OCS EIS/EA
BOEM 2024-0066
Docket Number: BOEM-2024-0055

SouthCoast Wind Project Final Environmental Impact Statement

November 2024

Volume II: Appendices

Bureau of Ocean Energy Management

Appendix A: Required Environmental Permits and Consultations

A.1 Required Environmental Permits

Table A-1 includes a summary of federal, state, and local permits or approvals that are required for the SouthCoast Wind Project's (Project) implementation.

Table A-1. Required environmental permits and consultations for the proposed Project

Agency/Regulatory Authority	Permit/Approval	Status
Federal (Portions of the Project within Federal Jurisdiction)		
Bureau of Ocean Energy Management (BOEM)	Construction and Operations Plan (COP) Approval	COP filed with BOEM February 15, 2021. Updates to the COP were submitted August 30, 2021, October 28, 2021, March 17, 2022, December 22, 2022, September 10, 2023, and July 31, 2024.
Department of Defense (DoD)	Informal Project Notification Form	Submitted May 2020.
National Marine Fisheries Service (NMFS)	Marine Mammal Protection Act Incidental Take Regulations and Letter of Authorization	Letter of Authorization Application for offshore construction and operations filed March 18, 2022, and deemed Complete by NMFS September 19, 2022.
U.S. Army Corps of Engineers (USACE)	Clean Water Act Section 404 and Rivers and Harbors Act Section 10 Individual Permit	Submitted December 2022; application deemed complete by USACE February 2, 2023.
U.S. Coast Guard (USCG)	Private Aids to Navigation authorization	Planned.
USCG	Local Notice to Mariners per Ports and Waterways Safety Act	Planned.
U.S. Environmental Protection Agency (USEPA)	Clean Air Act Outer Continental Shelf Air Permit	Submitted November 23, 2022; application deemed complete by USEPA April 7, 2023.
USEPA	National Pollutant Discharge Elimination System (NPDES) General Permit for Construction Activities	Submitted October 31, 2022; application deemed complete September 29, 2023.
USEPA	NPDES General Permit for Construction Activities (onshore at Brayton Point)	To be determined.
Federal Aviation Administration	Determination of No Hazard, if required	It is not currently anticipated that a Determination of No Hazard will be required for offshore structures in the lease area due to their location outside of 12 nautical miles (22 kilometers). Nor will this be required for the

Agency/Regulatory Authority	Permit/Approval	Status
		onshore substation or converter stations due to the maximum height of these structures. SouthCoast Wind Energy LLC continues to engage with the Federal Aviation Administration regarding whether any review and/or authorization is required for offshore equipment deployed to support horizontal directional drilling installation of the export cables.
Bureau of Safety and Environmental Enforcement	Oil Spill Response Plan	Filed with the COP February 15, 2021.
State (Portions of the Project within State Jurisdiction)		
Massachusetts Executive Office of Energy and Environmental Affairs (EEA)	Massachusetts Environmental Policy Act (MEPA) Environmental Notification Form (ENF) and/or Environmental Impact Report (EIR) and Certificate of Secretary of EEA	Project 1: Brayton Point ENF filed August 12, 2022. ENF certificate issued October 11, 2022. Project 1 Final EIR filed July 21, 2023. Supplemental Final EIR filed October 31, 2023. Certificate from EEA Secretary issued December 15, 2023. Project 2: ENF, Draft EIR, and Final EIR filings planned for Q1 2025.
Massachusetts Energy Facility Siting Board (MA EFSB)	Siting Petition pursuant to General Law (G.L.) c. 164, 69J and Certificate of Environmental and Public Need	Project 1: Brayton Point MA EFSB filed May 27, 2022. Decision anticipated in Quarter 1 2024. Project 2: Filing planned for Q4 2024.
Massachusetts Department of Public Utilities	Section 72 petition pursuant to G.L. c. 164, 72 and Zoning petition pursuant to G.L. c. 40A, 3	Project 1: Filed May 27, 2022, for Brayton Point. Project 2: Filing planned for Q4 2024.
Massachusetts Department of Environmental Protection	Chapter 91 Waterways License/Permit for dredge, fill, or structures in waterways or tidelands	Project 1: Filed December 20, 2023. Project 2: Filing planned for after completion of MEPA review.
	Section 401 Water Quality Certification	Project 1: Filed December 20, 2023. Project 2: Filing planned after completion of MEPA review.
Massachusetts Office of Coastal Zone Management	Coastal Zone Management Consistency Determination	Projects 1 and 2: Submitted February 15, 2021. Updates provided January 13, 2022. Consistency Determination anticipated in April 2024. Executed a third stay on November 8, 2023, extending the deadline for Coastal Zone Management's Federal Consistency Decision on or before April 10, 2024. Executed a fourth stay agreement on March 26, 2024, extending the deadline for Coastal Zone Management's Federal Consistency Decision on or before May 31, 2024. Executed a fifth stay agreement on

Agency/Regulatory Authority	Permit/Approval	Status
		May 15, 2024, extending the deadline for Coastal Zone Management's Federal Consistency Decision on or before July 31, 2024.
Massachusetts Department of Transportation	State Highway Access/Easement/Right-of-Way Permits (if required)	Projects 1 and 2: Filing planned prior to construction, if needed.
Massachusetts Historical Commission	Project Notification Form/Field Investigation Permits (980 Code of Massachusetts Regulations 70.00)	Projects 1 and 2: Brayton Point Project Notification Form submitted July 26, 2021. Brayton Point Terrestrial Archaeological Resources Assessment (Phase 1A Report) filed March 14, 2022.
	Section 106 Consultation	Projects 1 and 2: Initiated October 1, 2021. Notice of Intent provided November 1, 2021.
Massachusetts Board of Underwater Archaeological Resources	Section 106 Consultation	Initiated September 29, 2021. NOI provided November 1, 2021.
Massachusetts Fisheries and Wildlife – Natural Heritage & Endangered Species Program (NHESP)	Conservation and Management Permit (if needed) or No-Take Determination	Projects 1 and 2: Massachusetts's NHESP issued letter identifying state-listed protected species in proposed Brayton Point Project Area April 28, 2022 (NHESP Tracking No. 19-38917); determined that site is not mapped as Priority or Estimated Habitat.
Rhode Island Coastal Resources Management Council (RICRMC)	Coastal Zone Management Consistency Determination	Federal Consistency Concurrence issued December 19, 2023.
RICRMC	Freshwater Wetlands Permit	Project 1: Filed February 24, 2023. Updated filing March 6, 2023. Project 2: Planned.
RICRMC	Category B Assent and Submerged Lands License	Project 1: Filed February 24, 2023. Updated filing March 6, 2023. Project 2: Planned for Q4 2024.
Rhode Island Energy Facility Siting Board (RI EFSB)	Certificate of necessity/public utility	Project 1: Filed May 31, 2022. Project 2: Planned for Q4 2024.
Rhode Island Historical Preservation and Heritage Commission (RIHPHC)	Archaeological Permit	Projects 1 and 2: Phase 1 permit issued December 17, 2021. TARA (Phase 1A/1B Report) filed March 14, 2022. Marine Archaeological Resources Assessment submitted March 16, 2022.
RIHPHC	Section 106 Consultation	Initiated November 1, 2021.
Rhode Island Department of Environment	Water Quality Certification and Dredging Permit	Project 1: Filed March 17, 2023. Application deemed complete November 15, 2023. Secured

Agency/Regulatory Authority	Permit/Approval	Status
		401 Water Quality Certificate and Marine Dredge Permit March 14, 2024. Project 2: Planned.
Rhode Island Department of Environment	Rhode Island Pollution Discharge Elimination System General Permit for Stormwater Discharge Associated with Construction Activity	Projects 1 and 2: Planned.
Rhode Island Department of Transportation	Utility Permit/Physical Alteration Permit	Projects 1 and 2: Planned.
Local (Portions of the Project within Local Jurisdiction)		
Cape Cod Commission	Development of Regional Impact Review (if needed)	Planned (if needed).
Martha's Vineyard Commission	Development of Regional Impact Review (if needed)	Planned (if needed).
Falmouth, Somerset Planning and Zoning Boards	Local Planning/Zoning Approvals (if needed)	Falmouth Zoning Board: MA EFSB Zoning exemption petition filed November 17, 2021. Planned (if needed). Somerset Planning and Zoning Board: MA EFSB Zoning exemption petition filed May 27, 2022. Decision anticipated in Quarter 4 2024.
Somerset Conservation Commissions	Notice of Intent and Order of Conditions (Massachusetts Wetland Protection Act and municipal wetland non-zoning bylaws) (if needed)	Project 1: Filings planned for Quarter 1 2024. Project 2: Planned.
Swansea Conservation Commission	Notice of Intent and Order of Conditions (Massachusetts Wetlands Protection Act)	Notice of Intent filed on March 8, 2024.
Portsmouth Planning and Zoning Board(s)	Local Planning/Zoning Approval(s) (if needed)	Planned (if needed).
Falmouth, Edgartown, Oak Bluffs, Tisbury, and Nantucket Conservation Commissions	Notice of Intent and Order of Conditions (Massachusetts Wetlands Protection Act and municipal wetland non-zoning bylaws) (if needed)	Planned (if needed).
Falmouth, Portsmouth, and Somerset Department of Public Works, Board of Selectmen, and/or Town Council	Street Opening Permits/Grants of Location	Planned.

A.2 Consultation and Coordination

A.2.1 Introduction

This section discusses public, Tribal, and agency involvement leading up to the preparation and publication of the Final Environmental Impact Statement (EIS), including formal consultations, cooperating agency exchanges, the public scoping comment period, the Draft EIS public comment period, and correspondence. Interagency consultation, coordination, and correspondence throughout the development of this Final EIS occurred primarily through virtual meetings, teleconferences, and written communications (including email). BOEM coordinated with numerous agencies throughout the development of this document, as listed in Section A.2.5.2, *Cooperating Agencies*.

A.2.2 Consultations and Authorizations

The following section provides a summary and status of each consultation. The Bureau of Safety and Environmental Enforcement (BSEE), U.S. Army Corps of Engineers (USACE), and U.S. Environmental Protection Agency (USEPA) are co-action agencies for the Endangered Species Act (ESA), Magnuson-Stevens Fishery Conservation and Management Act (MSA), and National Historic Preservation Act (NHPA) consultations.

A.2.2.1 Coastal Zone Management Act

The Coastal Zone Management Act requires federal actions within the coastal zone or within the geographic location descriptions (i.e., areas outside the coastal zone in which an activity would have reasonably foreseeable coastal effects) affecting any land or water use or natural resource of the coastal zone be consistent with the enforceable policies of a state's federally approved coastal management program. A portion of the Project, specifically the export cable components, is within Massachusetts's and Rhode Island's designated coastal zone and will require a federal consistency review under the Coastal Zone Management Act. SouthCoast Wind Energy LLC's (SouthCoast Wind's) Construction and Operations Plan (COP) (SouthCoast Wind 2024) provided the necessary data and information under 15 Code of Federal Regulations (CFR) 930.58. The state's concurrence is required before BOEM may approve or approve with conditions the SouthCoast Wind COP per 30 CFR 585.628(f) and 15 CFR 930.130(1).

A.2.2.2 Endangered Species Act

Section 7(a)(2) of the ESA of 1973, as amended (16 United States Code [USC] 1531 et seq.), requires that each federal agency ensure that any action authorized, funded, or carried out by the agency is not likely to jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of critical habitat of those species. When the action of a federal agency may affect a protected species or its critical habitat, that agency is required to consult with either the National Marine Fisheries Service (NMFS) or U.S. Fish and Wildlife Service (USFWS), depending upon the jurisdiction. Pursuant to 50 CFR 402.07, BOEM has accepted designation as the lead federal agency for the purposes of fulfilling interagency consultation under Section 7 of the ESA for listed species under the jurisdiction of NMFS and USFWS. BOEM consulted on the proposed activities considered in this Final EIS with both NMFS and USFWS and prepared Biological Assessments for listed species under their respective jurisdictions. Consultation with USFWS and NMFS pursuant to Section 7 of the ESA concluded with the issuance of Biological Opinions from each agency in September 2023 and November 2024, respectively.

A.2.2.3 Government-to-Government Tribal Consultation

Executive Order 13175 commits federal agencies to engage in government-to-government consultation with Tribal Nations when federal actions have Tribal implications, and Secretarial Order No. 3317 requires U.S. Department of the Interior agencies to develop and participate in meaningful consultation with federally recognized Tribal Nations where a Tribal implication may arise. A June 29, 2018, memorandum outlines BOEM's current Tribal consultation policy (BOEM 2018). This memorandum states that "consultation is a deliberative process that aims to create effective collaboration and informed federal decision-making" and is in keeping with the spirit and intent of the NHPA and National Environmental Policy Act (NEPA), Executive and Secretarial Orders, and U.S. Department of the Interior Policy (BOEM 2018). BOEM implements Tribal consultation policies through formal government-to-government consultation, informal dialogue, collaboration, and other engagement.

From September 29 to November 1, 2021, BOEM initiated formal consultation with eight Tribal nations under the NHPA and invited them to be NHPA Section 106 consulting parties to the Project through individual letters mailed and emailed to Tribal leaders with the Delaware Tribe of Indians, Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, Mohegan Tribe of Connecticut, The Delaware Nation, The Narragansett Indian Tribe, The Shinnecock Indian Nation, and Wampanoag Tribe of Gay Head (Aquinnah). Five Tribal nations responded that they would like to participate as consulting parties to the Project: Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, The Narragansett Indian Tribe, The Shinnecock Indian Nation, and Wampanoag Tribe of Gay Head (Aquinnah). The Delaware Tribe of Indians and Mohegan Tribe of Connecticut did not respond to BOEM's initiation of consultation; however, BOEM has included these Tribal Nations in all consulting party communications and considers them consulting parties.

On October 8, 2021, BOEM sent a Memorandum of Understanding to the Delaware Tribe of Indians, Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, Mohegan Tribe of Connecticut, The Delaware Nation, The Narragansett Indian Tribe, The Shinnecock Indian Nation, and Wampanoag Tribe of Gay Head (Aquinnah) to establish a cooperating agency relationship with the purpose of preparing an EIS. One Tribe, the Delaware Nation, declined the invitation to be a consulting party on October 13, 2021.

On November 2, 2021, BOEM sent another set of letters and emails to Tribal leaders notifying them that the Notice of Intent (NOI) to prepare an EIS for the Project was issued that day and noted that the scoping comment period was open until December 2, 2021. The letter also offered a government-to-government consultation meeting to discuss the public scoping information for the Project and to request input regarding alternatives for consideration, the identification of historic properties, potential effects to historic properties, and potential measures to avoid, minimize and/or mitigate impacts on environmental and cultural resources to be analyzed in the EIS. BOEM held a government-to-government meeting with the Tribal Nations that responded—Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, and Wampanoag Tribe of Gay Head (Aquinnah)—on November 19, 2021. The Tribal Nations expressed interest in continuing consultation for offshore wind and emphasized the importance of early consultation in Project development.

On May 2, 2022, BOEM held a government-to-government meeting specifically with the Chairwoman, Tribal Historic Preservation Officer, and council members of the Wampanoag Tribe of Gay Head (Aquinnah). In the meeting, BOEM introduced and discussed the overall renewable energy program and process and summarized details and status of projects off the coast of New England. Topics identified for future discussion included cumulative visual simulations and resource impacts, the transmission process that is part of a lease, decommissioning process and oversight, proposed mitigation plans and agreements, and the Tribal capacity-building initiatives.

On June 1, 2022, BOEM held a government-to-government meeting with the Chairwoman and Council members of the Wampanoag Tribe of Gay Head (Aquinnah). This meeting was a follow up to the May 2, 2022 meeting to continue the collective conversation on various topics and Tribal concerns related to offshore wind development off the New England coast.

On June 2, 2022, the BOEM Director met in-person with the Mashpee Wampanoag Tribe to provide the Tribal Council with an overview of the current state of wind farm permitting off the coast of New England, including the Gulf of Maine; discuss and receive feedback on project and regional biological and economic concerns and potential mitigation strategies; discuss and receive feedback on cumulative visual impacts and simulations; discuss and receive feedback on other programmatic topics including transmission as part of a lease and capacity-building initiatives.

On September 1, 2022, BOEM held a government-to-government meeting with members of the Mashpee Wampanoag Tribe, the Wampanoag Tribe of Gay Head (Aquinnah), and the Mashantucket Pequot Tribal Nation. The meeting provided an overview of the SouthCoast Wind Project, including benthic habitat impacts, and overall concerns related to offshore wind permitting.

On January 17, 2024, BOEM held a government-to-government meeting with the Chairwoman of the Wampanoag Tribe of Gay Head (Aquinnah). This meeting was held in response to a letter sent on January 12, 2024, articulating concerns about offshore renewable energy. The meeting covered multiple offshore wind projects located off the New England coast. On February 7, 2024, BOEM held a government-to-government meeting with the Tribal Historic Preservation Officer from the Mashpee Wampanoag Tribe to discuss mitigation measures in the Section 106 Memorandum of Agreement.

On October 25, 2024, BOEM staff met with the Tribal Historic Preservation Officers from the Mashantucket Pequot Tribal Nation and the Wampanoag Tribe of Gay Head (Aquinnah) to discuss the SouthCoast Wind Section 106 Memorandum of Agreement. On November 1, 2024, BOEM staff met with the Tribal Historic Preservation Officers of the Mashantucket Pequot Tribal Nation, the Wampanoag

Tribe of Gay Head (Aquinnah), and the Mashpee Wampanoag Tribe to continue discussion about the SouthCoast Wind Section 106 Memorandum of Agreement.

A.2.2.4 National Historic Preservation Act

Section 106 of the NHPA (54 USC 306108) and its implementing regulations (36 CFR 800) require federal agencies to consider the effects of their undertakings on historic properties and afford the Advisory Council on Historic Preservation (ACHP) an opportunity to comment. BOEM has determined that the proposed Project is an undertaking subject to Section 106 review. The construction of wind turbine generators (WTGs) and offshore substation platforms (OSPs), installation of interarray cables, and development of staging areas are ground- or seabed-disturbing activities that may adversely affect archaeological resources. The presence of WTGs may also introduce visual elements out of character with the historic setting of historic structures or landscapes; in cases where historic setting is a contributing element of historic properties' eligibility for the National Register of Historic Places, the Project may adversely affect those historic properties.

The Section 106 regulations at 36 CFR 800.8 provide for use of the NEPA substitution process to fulfill a federal agency's NHPA Section 106 review obligations in lieu of the procedures set forth in 36 CFR 800.3 through 800.6. This process is commonly known as "NEPA substitution for Section 106" and BOEM is using this process and documentation required for the preparation of this EIS and the Record of Decision (ROD) to comply with Section 106. Appendix I of this Final EIS contains BOEM's Determination of Effect for NHPA Section 106 Consultation, which includes a description and summary of BOEM's NHPA Section 106 consultations. BOEM will continue consulting with the Massachusetts Historical Commission (the Massachusetts State Historic Preservation Officer [SHPO]), the Rhode Island Historical Preservation and Heritage Commission (RIHPHC), the Rhode Island SHPO, the Massachusetts Board of Underwater Archaeological Resources (BUAR), ACHP, federally recognized Tribal Nations, and other consulting parties regarding the Finding of Adverse Effect and the resolution of adverse effects.

BOEM has conducted five Section 106 consultation meeting(s) regarding the identification of historic properties, BOEM's Finding of Adverse Effect, and resolution of adverse effects on July 7, 2022; March 16, 2023; January 24, 2024; July 15, 2024; and October 8, 2024. BOEM fulfilled public involvement requirements for Section 106 of the NHPA through the NEPA public scoping and public meetings process, pursuant to 36 CFR 800.2(d)(3). The Scoping Summary Report (BOEM 2022), available on BOEM's Project-specific website, summarizes comments on historic preservation issues.

On September 29, 2021, BOEM initiated consultation with eight federally recognized Tribal nations: Delaware Tribe of Indians, Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, Mohegan Tribe of Connecticut, The Delaware Nation, The Narragansett Indian Tribe, The Shinnecock Indian Nation, and Wampanoag Tribe of Gay Head (Aquinnah) (Section A.2.2.3, *Government-to-Government Tribal Consultation*). The following five Tribal Nations notified BOEM of their interest in participating as a consulting party: the Mashantucket (Western) Pequot Tribal Nation on October 19, 2021; Mashpee Wampanoag Tribe on October 6, 2021; The Narragansett Indian Tribe on November 1, 2021; The Shinnecock Indian Nation on February 4, 2022; and Wampanoag Tribe of Gay Head

(Aquinnah) on November 1, 2021. The Delaware Tribe of Indians and Mohegan Tribe of Connecticut did not respond to BOEM's initiation of consultation; however, BOEM has included these Tribal nations in all consulting party communications and considers them consulting parties. One Tribe, The Delaware Nation, declined the invitation to be a consulting party on October 13, 2021. BOEM requested information from Tribal consulting parties on sites of religious and cultural significance to the Tribal nations that the proposed Project could affect, and BOEM offered its assistance in providing additional details and information on the proposed Project to the Tribal Nations.

From September 29 to October 7, 2021, BOEM corresponded with governments and organizations by mail and email to provide information about the Project and extend an invitation to be a consulting party to the NHPA Section 106 review of the COP. BOEM also used this correspondence to notify of its intention to use the NEPA process for Section 106 purposes, as described in 36 CFR 800.8(c), during its review. On November 1, 2021, BOEM notified consulting parties of its issuance of a NOI to prepare an EIS consistent with NEPA regulations to assess the potential impacts of the Proposed Action and alternatives. For additional information on Section 106 consultation and coordination, see Appendix I, Section I.2.2.3, *NHPA Section 106 Consultations.* Participants that have accepted consulting party status for the NHPA Section 106 Consultation are listed in Table A-2. During the consultations, additional parties were made known to BOEM and were added as they were identified; these additional parties are included in this list.

Table A-2. NHPA Section 106 consulting parties

Government or Organization Type	Participating Government or Organization Name
Federal agencies or facilities	ACHP BSEE National Park Service Naval Facilities Engineering Systems Command (NAVFAC) HQ USACE US Navy, Naval History and Heritage Command
Federally recognized Tribal Nations	Delaware Tribe of Indians Mashantucket (Western) Pequot Tribal Nation Mashpee Wampanoag Tribe Mohegan Tribe of Connecticut The Narragansett Indian Tribe The Shinnecock Indian Nation Wampanoag Tribe of Gay Head (Aquinnah)
SHPOs and state agencies	BUAR Massachusetts Historical Commission RIHPHC
Non-federally recognized tribes	Chappaquiddick Tribe of Wampanoag Nation
Local governments	Cape Cod Commission City of East Providence, Rhode Island City of New Bedford and New Bedford Port Authority, Massachusetts Martha's Vineyard Commission

Government or Organization Type	Participating Government or Organization Name
	Nantucket Historic District Commission Nantucket Historical Commission Nantucket Planning & Economic Development Commission (represented by Cultural Heritage Partners [CHP]) Town of Aquinnah, Massachusetts Town of Barnstable, Historical Commission, Massachusetts Town of Bristol, Rhode Island Town of Falmouth, Massachusetts Town of Jamestown, Rhode Island Town of Middletown, Rhode Island Town of Nantucket, Massachusetts (represented by CHP) Town of Somerset, Massachusetts, Historical Commission Town of South Kingstown, Rhode Island Town of Swansea, Massachusetts Town of Warren, Rhode Island Town of Westport, Massachusetts
Nongovernmental organizations or groups	Alliance to Protect Nantucket Sound Gay Head Lighthouse Advisory Board Nantucket Preservation Trust Oak Grove Cemetery Association of Falmouth, Inc. The Maria Mitchell Association
Lessee	SouthCoast Wind Energy LLC

A.2.2.5 Magnuson-Stevens Fishery Conservation and Management Act

Pursuant to Section 305(b) of the MSA, federal agencies are required to consult with NMFS on any action that may result in adverse effects on Essential Fish Habitat (EFH). NMFS regulations implementing the EFH provisions of the MSA can be found at 50 CFR 600. As provided for in 50 CFR 600.920(b), BOEM has accepted designation as the lead agency for the purposes of fulfilling EFH consultation obligations under Section 305(b) of the MSA. Certain Outer Continental Shelf (OCS) activities authorized by BOEM may result in adverse effects on EFH and, therefore, require consultation with NMFS. BOEM prepared and submitted an EFH Assessment to NMFS, which was deemed complete for EFH consultation to initiate on June 24, 2024. NMFS issued EFH conservation recommendations on September 23, 2024. BOEM will respond to NMFS regarding how it will proceed with the action, and relevant terms and conditions will be incorporated into the ROD.

A.2.2.6 Marine Mammal Protection Act

Section 101(a) of the Marine Mammal Protection Act (MMPA) (16 USC 1361) prohibits persons or vessels subject to the jurisdiction of the United States from taking any marine mammal in waters or on lands under the jurisdiction of the United States or on the high seas (16 USC 1372(a)(l), (a)(2)). Sections 101(a)(5)(A) and (D) of the MMPA provide exceptions to the prohibition on take, which give NMFS the authority to authorize the incidental but not intentional take of small numbers of marine mammals, provided certain findings are made and statutory and regulatory procedures are met. Entities seeking to obtain authorization for the incidental take of marine mammals under NMFS jurisdiction must submit such a request (in the form of an application). Incidental Take Authorizations may be issued as either (1) regulations and associated Letters of Authorization, or (2) an Incidental Harassment Authorization. Letters of Authorizations may be issued for up to a maximum period of 5 years, and Incidental Harassment Authorizations may be issued for a maximum period of 1 year. NMFS has also promulgated regulations to implement the provisions of the MMPA governing the taking and importing of marine mammals (50 CFR 216) and has published application instructions that prescribe the procedures necessary to apply for an Incidental Take Authorization. Applicants seeking to obtain authorization for the incidental take of marine mammals under NMFS' jurisdiction must comply with these regulations and application instructions in addition to the provisions of the MMPA.

Once NMFS determines an application is adequate and complete, NMFS has a corresponding duty to determine whether and how to authorize take of marine mammals incidental to the activities described in the application. To authorize the incidental take of marine mammals, NMFS evaluates the best available scientific information to determine whether the take would have a negligible impact on the affected marine mammal species or stocks and an immitigable impact on their availability for taking for subsistence uses. NMFS must also prescribe the "means of effecting the least practicable adverse impact" on the affected species or stocks and their habitat, and on the availability of those species or stocks for subsistence uses, as well as monitoring and reporting requirements.

SouthCoast Wind submitted an application for incidental take regulations and a Letter of Authorization to NMFS on March 18, 2022. The application was reviewed and considered complete on September 19, 2022. NMFS published a Notice of Receipt in the *Federal Register* on October 17, 2022. NMFS published the proposed Incidental Take Regulations in the *Federal Register* on June 25, 2024.

A.2.3 Clean Water Act and Rivers and Harbors Act

Under Section 404 of the Clean Water Act (CWA), USACE regulates the discharge of dredged or fill material into the waters of the United States, including wetlands. A permit from USACE is required regardless of whether a discharge of dredged or fill material is temporary or permanent. Under Section 10 of the Rivers and Harbors Act (RHA), USACE regulates construction of any structures and work that are located in or that affect navigable waters of the United States and prohibits obstructions to the navigable capacity of these waters. USACE's authority to prevent obstructions to navigation in navigable waters of the United States was extended to artificial islands, installations, and other devices located on the seafloor, to the seaward limit of the OCS, by Section 4(f) of the Outer Continental Shelf Lands Act of 1953 as amended (43 USC 1333; 33 CFR 320.2). A permit from USACE is required for structures that would be located on the seafloor of the OCS, as well as for structures or work that would affect the course, location, or condition of a navigable water of the United States. SouthCoast Wind submitted a Department of the Army permit application to USACE under Section 404 of the CWA and Section 10 of the RHA on February 2, 2023.

A.2.4 Clean Air Act

The OCS Air Regulations (40 CFR Part 55) establish the applicable air pollution control requirements, including provisions related to permitting, monitoring, reporting, fees, compliance, and enforcement, for facilities subject to the Clean Air Act Section 328. SouthCoast Wind submitted an OCS Air Permit application to USEPA on November 23, 2022. USEPA deemed the application complete on April 7, 2023.

A.2.5 Development of Final Environmental Impact Statement

This section provides an overview of the development of the Final EIS, including public scoping, cooperating agency involvement, and distribution of the Draft EIS for public review and comment.

A.2.5.1 Scoping

On November 1, 2021, BOEM issued an NOI to prepare an EIS consistent with NEPA regulations (42 USC 4321 et seq.) to assess the potential impacts of the Proposed Action and alternatives (86 Federal Register 60270). The NOI commenced a public scoping process for identifying issues and potential alternatives for consideration in the EIS. The formal scoping period was from November 1 through December 1, 2021. Three virtual scoping meetings were held on November 10, 15, and 18, 2021. During this timeframe, federal agencies, state and local governments, and the general public had the opportunity to help BOEM identify potential significant resources and issues, impact-producing factors, reasonable alternatives (e.g., size, geographic, seasonal, or other restrictions on construction and siting of facilities and activities), and potential mitigation measures to analyze in the EIS, as well as provide additional information. BOEM also used the NEPA scoping process to initiate the Section 106 consultation process under the NHPA (54 USC 300101 et seq.), as permitted by 36 CFR 800.2(d)(3), which requires federal agencies to assess the effects of projects on historic properties. Additionally, BOEM informed its Section 106 consultation by seeking public comment and input through the NOI regarding the identification of historic properties or potential effects on historic properties from activities associated with approval of the COP. The NOI requested comments from the public in written form, delivered by mail, or through the regulations.gov web portal. The public could also submit oral comments at the three virtual scoping meetings hosted by BOEM.

A Scoping Summary Report (BOEM 2022) summarizing the submissions received and the methods for analyzing them is available on BOEM's website at https://www.boem.gov/southcoast-wind. In addition, all public scoping submissions received can be viewed online at http://www.regulations.gov by typing "BOEM-2021-0062" in the search field. As detailed in the Scoping Summary Report, the resource areas or NEPA topics most referenced in the scoping comments include NEPA/Public Involvement Process; recreation and tourism; mitigation and monitoring; commercial fisheries and for-hire recreational fishing; birds; demographics, employment and economics; and others.

A.2.5.2 Cooperating Agencies

BOEM invited other federal agencies and state, Tribal, and local governments to consider becoming cooperating agencies in the preparation of the Final EIS. According to Council on Environmental Quality

(CEQ) guidelines, qualified agencies and governments are those with "jurisdiction by law or special expertise" (CEQ 1981). BOEM asked potential cooperating agencies to consider their authority and capacity to assume the responsibilities of a cooperating agency, and to be aware that an agency's role in the environmental analysis neither enlarges nor diminishes the final decision-making authority of any other agency involved in the NEPA process. BOEM also asked agencies to consider the "Factors for Determining Cooperating Agency Status" in Attachment 1 to CEQ's January 30, 2002, Memorandum for the Heads of Federal Agencies (CEQ 2002). BOEM held interagency meetings on August 6, 2021, September 23, 2021, January 5, 2022, March 8, 2022, October 28, 2022, and July 24, 2024, to discuss the environmental review process, schedule, responsibilities, consultation, and alternatives.

The following federal agencies and state governments have supported preparation of the Final EIS as cooperating agencies.

- NMFS
- USACE
- BSEE
- USEPA
- U.S. Coast Guard (USCG)
- Massachusetts Office of Coastal Zone Management
- Rhode Island Coastal Resources Management Council (RICRMC)
- New York State Department of State

NMFS is serving as a cooperating agency pursuant to 40 CFR 1501.8 because the scope of the Proposed Action and alternatives involve activities that have the potential to affect marine resources under its jurisdiction by law and special expertise. As applicable, permits and authorizations are issued pursuant to the MMPA, as amended (16 USC 1361 et seq.); the regulations governing the taking and importing of marine mammals (50 CFR 216); the ESA (16 USC 1531 et seq.); and the regulations governing the taking, importing, and exporting of threatened and endangered species (50 CFR 222–226). In accordance with 50 CFR 402, NMFS also serves as the Consulting Agency under Section 7 of the ESA for federal agencies proposing action that may affect marine resources listed as threatened or endangered. NMFS has additional responsibilities to conserve and manage fishery resources of the United States, which include the authority to engage in consultations with other federal agencies pursuant to the MSA and 50 CFR 600 when proposed actions may adversely affect EFH. The MMPA is the only authorization for NMFS that requires NEPA compliance. NMFS intents to adopt BOEM's Final EIS if, after independent review and analysis, NMFS determines the Final EIS to be sufficient to support the regulatory decision.

USACE is serving as a cooperating agency pursuant to 40 CFR 1501.8 because the scope of the Proposed Action and alternatives involves activities that could affect resources under USACE's jurisdiction by law and special expertise. As applicable, permits and authorizations are issued pursuant to Section 404 of the CWA and Sections 10 and 14 of the RHA of 1899. Under Section 404 of the CWA, USACE regulates the discharge of dredged or fill material into waters of the United States. The landward limit of jurisdiction in tidal waters (33 CFR § 328.4) extends to the high tide line, whereas the seaward limit is 3.5 miles (3 nautical miles [nm]), as measured from the baseline of the territorial seas. The baseline from which the 3.5-mile (3-nm) limit of the territorial seas is measured is generally the line on the shore reached by the ordinary low tides but may also lie across the mouth of bays or elsewhere when the coast is not in direct contact with the open sea. The limit of Section 404 jurisdiction in non-tidal waters (33 CFR 328.4(c)) is as follows: (1) In the absence of adjacent wetlands, the jurisdiction extends to the ordinary high water mark, or (2) when adjacent wetlands are present, the jurisdiction extends beyond the ordinary high water mark to the limit of the adjacent wetlands. When the water of the United States consists only of wetlands, the jurisdiction extends to the limit of the wetland. Under Section 10 of the RHA, USACE regulates construction of any structures and work that are located in or that affect "navigable waters of the U.S." In tidal waters, the shoreward limit of navigable waters extends to the mean high water mark while the seaward limit coincides with the limit of the territorial seas. USACE's authority to prevent obstructions to navigation in navigable waters of the United States was extended to artificial islands, installations, and other devices located on the seafloor, to the seaward limit of the OCS, by Section 4(f) of the Outer Continental Shelf Lands Act of 1953, as amended (43 USC 1333; 33 CFR 320.2).

BSEE is serving as a cooperating agency pursuant to 40 CFR 1501.8 because the scope of the Proposed Action and alternatives involves activities that could affect marine resources under its jurisdiction by law and special expertise; and safety, compliance, and enforcement issues. Pursuant to a December 2020 Memorandum of Agreement between BOEM and BSEE, BSEE conducts activities, consults, and advises BOEM on safety and environmental enforcement for renewable energy projects.

USEPA is serving as a cooperating agency pursuant to 40 CFR 1501.8 because the scope of the Proposed Action and alternatives involves activities that could affect resources under its jurisdiction by law and special expertise, including air quality and water quality. USEPA will also be providing authorization for an OCS air permit, an NPDES permit, and using the analysis of the EIS as information in the permit process.

USCG is serving as a cooperating agency pursuant to 40 CFR 1501.8 because the scope of the Proposed Action and alternatives involves activities that could affect navigation and safety issues that fall under its jurisdiction by law and special expertise. USCG is the Federal On Scene Coordinator for spills in the Lease Area. USCG encourages coordination with all stakeholders to ensure information regarding worst case discharges and response strategies are incorporated into the Area Contingency Plan.

Massachusetts Office of Coastal Zone Management, RICRMC, and New York State Department of State are serving as cooperating agencies pursuant to 40 CFR 1501.8 because they have special expertise with respect to potential impacts that may occur as a result of the Proposed Action.

A.2.5.3 Distribution of the Draft Environmental Impact Statement for Review and Comment

On February 17, 2023, BOEM published a Notice of Availability for the Draft EIS. The Draft EIS was made available in electronic format for public viewing at https://www.boem.gov/southcoast-wind. Hard copies and digital copies of the Draft EIS were delivered to entities as requested. The Notice of Availability commenced a 45-day public review and comment period of the Draft EIS. On April 4, 2023, BOEM announced a 15-day extension to the comment period, which concluded on April 18, 2023. BOEM held three virtual public hearings to solicit feedback and identify issues for consideration in preparing the Final EIS. Throughout the public review and comment period, government agencies, members of the public, and interested stakeholders had the opportunity to provide comments on the Draft EIS in various ways, including the following:

- In hard copy form, delivered by mail, enclosed in an envelope labeled "Mayflower Wind COP EIS" and addressed to Program Manager, Office of Renewable Energy, Bureau of Ocean Energy Management, 45600 Woodland Road, Sterling, Virginia 20166.
- Through the regulations.gov web portal by navigating to https://www.regulations.gov/, searching for docket number "BOEM-2023-0011," and submitting a comment.
- By attending one of the public meetings on the dates listed in the notice of availability and providing written or verbal comments.

BOEM reviewed and considered all comment submissions in the development of the Final EIS. BOEM's evaluation of public submissions focused on those comments within the submissions that were identified as substantive. EIS Appendix N, *Responses to Comments on the Draft Environmental Impact Statement*, describes the public comment processing methodology and includes comment responses. All public comment submissions received on the Draft EIS can be viewed online at https://www.regulations.gov/ by typing "BOEM-2023-0011" in the search field.

A.2.5.4 Distribution of the Final Environmental Impact Statement

The EIS is available in electronic form for public viewing at https://www.boem.gov/southcoast-wind. Hard copies and digital copies of the Final EIS can be requested by contacting the Program Manager, Office of Renewable Energy Programs in Sterling, Virginia. Publication of the Final EIS initiates a minimum 30-day mandatory waiting period, during which BOEM is required to pause before issuing a ROD. The ROD will state clearly whether BOEM intends to approve, approve with conditions, or disapprove the COP for construction, operation, and eventual decommissioning of the Project. Notification will be provided as indicated in Appendix M, *Distribution List,* of the Final EIS.

Appendix B: Supplemental Information and Additional Figures and Tables

B.1 Wetlands

Table B-1 summarizes National Wetland Inventory (NWI) wetland communities in the Massachusetts part of the wetlands geographic analysis area. Table B-2 quantifies the potential wetland impacts based on NWI data for the Falmouth onshore components for the SouthCoast Wind Project (Project). These tables are similar to Table 3.5.8-1 and Table 3.5.8-3 in Section 3.5.8, *Wetlands*, respectively, but show NWI data instead of Massachusetts Department of Environmental Protection (MassDEP) wetland data. Note that the NWI GIS data were used for the analysis in Rhode Island in Section 3.5.8, *Wetlands*, including the impacts disclosed for Alternatives C-1 and C-2, so that information is not repeated here.

Table B-1. NWI wetland communities in the Massachusetts part of the geographic analysis area

Wetland Community	Falmouth Onshore Project Area	Percent of Total
Estuarine and Marine Wetland	4,901	34%
Freshwater Emergent Wetland	992	7%
Freshwater Forested/Shrub Wetland	8,600	59%
Total	**14,493**	**100%**

Source: USFWS 2021

Table B-2. NWI wetland impacts in the Falmouth Onshore Project area—Proposed Action

Onshore Project Component	Wetland Community	Impact (acres)	% Relative to Wetlands in GAA	Duration
Falmouth Onshore				
Onshore Export Cable Routes				
Worcester Avenue Route	N/A	0	0	N/A
Shore Street Route Eastern Option	N/A	0	0	N/A
Shore Street Route Western Option	N/A	0	0	N/A
Central Park Route	N/A	0	0	N/A
Lawrence Lynch to Cape Cod Aggregates Route	N/A	0	0	N/A
Paper Road – Thomas B Landers Road Deviation	N/A	0	0	N/A
Onshore Substation Locations				
Lawrence Lynch	N/A	0	0	N/A
Cape Cod Aggregates	N/A	0	0	N/A

Onshore Project Component	Wetland Community	Impact (acres)	% Relative to Wetlands in GAA	Duration
Underground Transmission Route and Point of Interconnection				
Underground Transmission Route from Cape Cod Aggregates to POI	Freshwater Forested/ Shrub Wetland	0.06	<0.1	Long term (> 5 years)
Point of Interconnection (Falmouth Switching Station)	N/A	0	0	N/A

Source: USFWS 2021
Note: The disturbance area used to calculate the potential wetland impact areas from export cables is based on a 40-foot-wide corridor along the cable route, except for the cable route from Cape Cod Aggregates to POI, which is a 100-foot-wide corridor.
GAA = geographic analysis area; N/A = not applicable; POI = point of interconnection

B.1.1 Characteristic Wetland Communities in the Falmouth Onshore Project Area

B.1.1.1 Red Maple Swamp

Red maple (*Acer rubrum*) swamps are the most common forested wetlands in Massachusetts (COP Appendix J, Section 4.1.4.1; SouthCoast Wind 2024). Within these wetlands, red maple is the dominant species in the tree stratum. The shrub layer within red maple swamps in Eastern Massachusetts typically includes sweet pepper-bush, highbush blueberry, northern arrow-wood (*Viburnum dentatum*), spicebush, and greenbrier (*Smilax rotundifolia*). Ferns are typically abundant with cinnamon fern (*Osmundastrum cinnamomeum*) being the most common. Other ferns include sensitive fern (*Onoclea sensibilis*), royal fern (*Osmunda regalis*), marsh fern (*Thelypteris palustris*), and spinulose wood fern (*Dryopteris carthusiana*). Skunk cabbage (*Symplocarpus foetidus*) is one of the most common herbaceous species (COP Appendix J, Section 4.1.4.1; SouthCoast Wind 2024).

B.1.1.2 Atlantic White Cedar Bog

Atlantic white cedar bogs are semi-forested, acidic, dwarf-shrub wetlands (Natural Heritage and Endangered Species Program [COP Appendix J, Section 4.1.4.1; SouthCoast Wind 2024]). Short (6–30 feet [2-10 meters]) Atlantic white cedar (*Chamaecyparis thyoides*) trees dominate the open canopy. An open to nearly continuous, low (3 feet [1 meter]) shrub layer often includes small Atlantic white cedars. Scattered red maple may be present with occasional associates including white and pitch pine, grey birch (*Betula populifolia*), and black spruce (*Picea mariana*). Scattered tall shrubs may be present and include highbush blueberry and swamp azalea. A dense low shrub layer is frequently comprised of leatherleaf, sheep laurel (*Kalmia angustifolia*), black huckleberry, rhodora (*Rhododendron canadense*), and bog rosemary (*Andromeda polifolia var. glaucophylla*). There is typically a well-formed sphagnum moss (*Sphagnum spp*.) layer below the shrubs, and large and small cranberry (*Vaccinium macrocarpon and V. oxycoccos*), sundews (*Drosera* spp.), and pitcher plants (*Sarracenia purpurea*) may be present (COP Appendix J, Section 4.1.4.1; SouthCoast Wind 2024).

B.1.1.3 Kettlehole Level Bog

Kettlehole level bogs are unique peatland ecosystems that develop in valley bottoms without inlets or outlets. Species composition in this ecosystem includes sphagnum moss blueberries, leatherleaf (*Chamaedaphne calyculata*), and species of laurel (*Kalmia spp*.). The Natural Heritage and Endangered Species Program identifies this ecosystem as Imperiled (COP Appendix J, Section 4.1.4.1; SouthCoast Wind 2024).

B.1.1.4 Shrub Swamp

Shrub swamps are shrub-dominated wetlands and often occur within overhead electric utility rights-of-way as a result of previous tree clearing for installation of the utility and subsequent integrated vegetation management activities that targets removal of tree species while allowing for continued growth and establishment of low-growing species, such as shrubs. The species composition of shrub swamps is highly variable and can include meadowsweet (*Spiraea alba var. latifolia*), steeplebush (*Spirea tomentosa*), swamp azalea, silky dogwood (*Swida amomum*), winterberry (*Ilex verticillata*), sweet gale (*Myrica gale*), and arrowwood. Low-growing, weak-stemmed shrubs include dewberry (*Rubus hispidus*), water-willow (*Decodon verticillatus*), and Canadian burnet (Sanguisorba canadensis). The herbaceous layer often includes common arrowhead (*Sagittaria latifolia*), skunk cabbage, ferns, sedges (*Carex* spp.), bluejoint grass (Calamagrostis canadensis), bur reed (*Sparganium* spp.), virgin's-bower (*Clematis virginiana*), swamp candles (*Lysimachia terrestris*), clearweed (*Pilea pumila*), and turtlehead (*Chelone glabra*). Sphagnum moss is often abundant. Invasive species include reed canary-grass (*Phalaris arundinacea*), glossy buckthorn (Frangula alnus), common buckthorn (*Rhamnus alnifolia*), and purple loosestrife (*Lythrum salicaria*) (COP Appendix J, Section 4.1.4.1; SouthCoast Wind 2024).

B.1.1.5 Emergent Marsh

The deep emergent marsh wetland type occurs along rivers, streams, lakes, ponds, and other waterbodies. Water depths are less than 3 feet (1 meter), though some depth of water is usually always present in most years and influences the vegetation present. Often this wetland type is part of a wetland mosaic with shrub swamp and forested wetland bordering the emergent portions of the wetland. Vegetation consists primarily of herbaceous species and graminoids. These often include broad-leaved cattail (*Typha latifolia*), sphagnum moss, wool-grass (*Scirpus cyperinus*), common threesquare (*Schoenoplectus pungens*), bluejoint grass, reed canary-grass, rice cut-grass (*Leersia oryzoides*), tussock-sedge (*Carex stricta*), arrow-leaf tearthumb (*Persicaria sagittata*), beggar-ticks (*Bidens* spp.), bedstraw (*Galium* spp.), common arrowhead, slender-leaved goldenrod (*Euthamia caroliniana*), marsh-fern, marsh St. John's-wort (*Triadenum virginicum*), Joe-Pye-weeds (*Eutrochium* spp.), bonesets (*Eupatorium* spp.), and water-horehound (*Lycopus* spp.). Areas with more permanent open water often support floating-leaved plants like water-lilies (*Nymphaea odorata and Nuphar* spp.). Shrubs can include red osier dogwood (*Swida sericea*), leatherleaf (*Chamaedaphne calyculata*), sweet-gale, meadowsweet, steeplebush, and highbush blueberry; however, shrub cover is sparse (COP Appendix J, Section 4.1.4.1; SouthCoast Wind 2024).

B.1.1.6 Highbush Blueberry Thicket

Highbush blueberry thickets are peatlands that host tall shrubs and sometimes small red maple trees. Common species within this ecosystem include the namesake highbush blueberry along with other common blueberry species including swamp azalea (*Rhododendron viscosum*), winterberry (*Ilex verticillata*), and sweet pepperbush (COP Appendix J, Section 4.1.4.1; SouthCoast Wind 2024).

B.1.1.7 Vernal pools

Vernal pools are temporary pools or ponds, typically occurring within wetlands, that fill with water in the fall or winter due to rainfall and seasonal high groundwater levels and remain ponded through the spring and into summer. Often vernal pools dry up completely by the middle or end of the summer, or at least every few years, which prevents fish populations from becoming established within the pool. The absence of fish is critical to the reproductive success of many amphibian and invertebrate species that rely exclusively on vernal pools to provide breeding habitat, including wood frog (*Lithobates sylvaticus*), mole salamanders (*Ambystoma* spp.), and fairy shrimp (*Eubranchipus* spp.). For this reason, vernal pools are a unique and sensitive aquatic habitat, and have specific protections under both the Massachusetts Wetlands Protection Act regulations (310 Code of Massachusetts Regulations [CMR] 10.00) and the U.S. Army Corps of Engineers New England District's General Permits for the Commonwealth of Massachusetts for activities subject to Corps jurisdiction in waters of the U.S., including wetlands (COP Appendix J, Section 4.1.4.1; SouthCoast Wind 2024).

B.2 Climate and Meteorology

The Atlantic seaboard is classified as a mid-latitude climate zone based upon the Köppen Climate Classification System. The region is characterized by mostly moist subtropical conditions, generally warm and humid in the summer with mild winters. The Massachusetts climate is characterized by frequent and rapid changes in weather, large daily and annual temperature ranges, large variations from year to year, and geographic diversity. During the winter, the main weather feature in the northeastern United States is the northeaster (cold-core extratropical cyclone). During the summer, convective thunderstorms occur frequently. The Atlantic hurricane season runs from June 1 to November 30.

The National Climatic Data Center (NCDC) defines distinct climatological divisions to represent geographic areas that are nearly climatically homogeneous. Locations within the same climatic division are considered to share the same overall climatic features and influences. The site of the Proposed Action is located within the Massachusetts coastal division (NOAA 2021).

B.2.1 Ambient Temperature

According to NCDC data for the Massachusetts coastal division, the average annual temperature is 50.5 degrees Fahrenheit (°F) (10.3 degrees Celsius [°C]), the average winter (December–February) temperature is 31.7°F (-0.2°C) and the average summer (June–August) temperature is 69.6°F (20.9°C), based on data collected from 1987 through 2019. Table B-3 summarizes average temperatures at the individual recording stations within the general area of the proposed Project area. Data for some stations as seen in the table are reflective of different years of weather observations; however, the general pattern shows little difference across the listed locations.

Table B-3. Representative temperature data

Station	Annual Average °F/°C	Annual Maximum °F/°C	Annual Minimum °F/°C
Coastal Division	50.5/10.3	59.2/15.1	41.8/5.4
Nantucket	50.7/10.4	57.6/14.2	43.9/6.6
Martha's Vineyard	51.2/10.7	59.1/15.1	43.2/6.2
Hyannis	51.1/10.6	58.8/14.9	43.4/6.3
Buzzards Bay Buoy	50.4/10.2	N/A	N/A
Nantucket Sound Buoy	52.4/11.3	N/A	N/A

Sources: NOAA 2019a (Coastal Division 2019 data; Nantucket 2019 data; Martha's Vineyard 2019 data; Hyannis 2019 data), NOAA 2019b (Buzzards Bay Buoy 2009-2019 data; Nantucket Sound Buoy 2009-2019 data).
°C = degrees Celsius; °F = degrees Fahrenheit; N/A = not available.

B.2.2 Wind Conditions

Prevailing winds in the middle latitudes over North America flow mostly west to east ("westerlies"). Westerlies within the Lease Area vary in strength, pattern, and directionality. Extreme wind conditions on the U.S. East Coast are influenced by both winter storms and tropical systems. Several northeasters occur each winter season, while hurricanes are rarer but potentially more extreme. The tropical systems, therefore, define the wind farm design, based on extreme wind speeds (those with recurrence periods of 50 years or more).

Table B-4 summarizes wind conditions in the Massachusetts coastal division. This table shows the monthly average wind speeds, monthly average peak wind gusts, and the hourly peak wind gusts for each individual month. Data from 2009 through 2019 show that monthly wind speeds range from a low of 11.97 miles per hour (mph) (19.27 kilometers per hour [km/hr]) in July to a high of 17.02 mph (27.38 km/hr) in January. The monthly wind peak gusts reach a maximum during November at 21.23 mph (34.17 km/hr). The one-hour average wind gusts reach a maximum during October at 64.65 mph (104.04 km/hr).

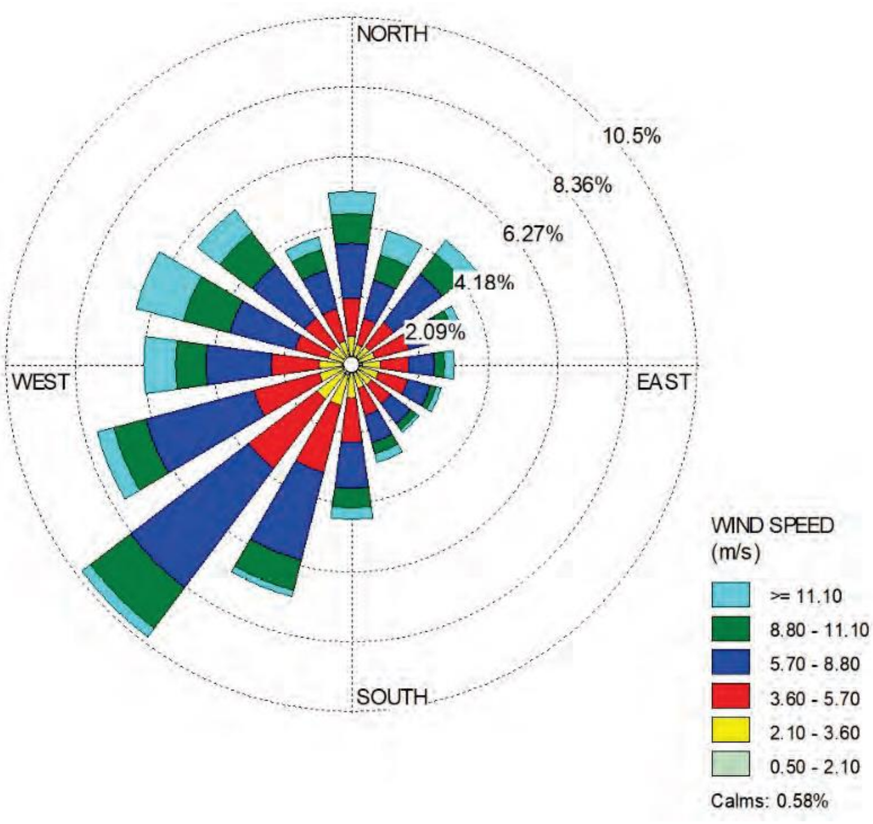
Table B-4. Representative wind speed data for the Massachusetts coastal division

Month	Monthly Average Wind Speed		Monthly Average Peak Gust		Peak One-Hour Average Gust	
	mph	km/hr	mph	km/hr	mph	km/hr
January	17.02	27.38	20.97	33.75	61.29	98.64
February	15.77	25.38	19.35	31.15	63.53	102.24
March	15.91	25.61	19.44	31.29	64.42	103.68
April	14.90	23.97	18.12	29.16	49.21	79.20
May	13.14	21.14	15.89	25.58	58.16	93.60

Month	Monthly Average Wind Speed		Monthly Average Peak Gust		Peak One-Hour Average Gust	
	mph	km/hr	mph	km/hr	mph	km/hr
June	12.31	19.81	14.93	24.03	44.52	71.64
July	11.97	19.27	14.49	23.32	57.04	91.80
August	12.48	20.08	15.14	24.37	59.95	96.48
September	13.92	22.40	17.08	27.48	51.90	83.52
October	16.45	26.48	20.40	32.82	64.65	104.04
November	17.01	27.38	21.23	34.17	57.71	92.88
December	15.99	25.73	19.84	31.93	59.50	95.76

Source: NOAA 2019b (National Data Buoy Center, Nantucket Sound Station 44020, 2009–2019).
km/hr = kilometer per hour; mph = miles per hour.

Throughout the year, wind direction is variable. However, seasonal wind directions are primarily focused from the west/northwest during the winter months (December–February) and from the south/southwest during the summer months (June–August). Figure B-1 shows a 5-year wind rose for Buoy Station 44020 (Nantucket Sound). Wind speeds are in meters per second. Percentages indicate how frequently the wind blows from that direction.



Source: NOAA 2019b.

Figure B-1. 5-year (2015–2019) wind rose for Nantucket Sound

B.2.3 Precipitation and Fog

Data from NCDC show that the annual average precipitation is 49.75 inches (126.37 centimeters) in the Massachusetts coastal division. Table B-5 shows monthly variations in average precipitation, which ranges from a high of 5.59 inches (14.20 centimeters) for October to a low of 3.30 inches (8.38 centimeters) in May.

Snowfall amounts can vary quite drastically within small distances. Data from the Martha's Vineyard Station (KMVY) shows that the annual snowfall average is approximately 23 inches (58.4 centimeters), and the month with the highest snowfall is February, averaging around 8 inches (20.3 centimeters).

Fog is a common occurrence along coastal Massachusetts. Fog is especially dense across the water south of Cape Cod toward the islands of Martha's Vineyard and Nantucket. Fog data were collected from 1997 to 2009 at the BUZM3 meteorological station located in Buzzard's Bay, approximately 25 miles (40 kilometers) from the Project area; and from 2007 to 2009 at the Martha's Vineyard Coastal Observatory (MVCO) meteorological station located 2 miles (3 kilometers) south of Martha's Vineyard (Merrill 2010). The data show that fog is most common in the Project area during the months of June, July, and August, with a typical range of 6 to 11 days per month with at least 1 hour of fog. In the winter, fog is much less frequent, with 3 or fewer days with at least 1 hour of fog.

Table B-5. Representative monthly precipitation data for the Massachusetts coastal division (2009–2019) [a]

Month	Average Precipitation	
	Inches	Centimeters
January	4.04	10.26
February	3.86	9.80
March	4.67	11.85
April	4.14	10.51
May	3.30	8.38
June	4.20	10.67
July	3.72	9.44
August	3.67	9.33
September	3.56	9.03
October	5.59	14.20
November	4.15	10.53
December	4.87	12.36
Annual Average	49.75	126.37

Source: NOAA 2019a.

[a] Precipitation is recorded in melted inches (snow and ice are melted to determine monthly equivalent). Data are representative of the Massachusetts coastal division.

The potential for icing conditions, i.e., atmospheric conditions that can lead to the deposition of ice from the atmosphere onto a structure, was also predicted based on data collected at the BUZM3 tower

(Merrill 2010). Icing is rare when the water temperature is greater than 43°F (6°C), so in most months of the year, and for many days during the winter months, there is no potential for icing to occur. The data show that moderate icing (defined by the Federal Aviation Administration as a rate of accumulation such that short encounters become potentially hazardous) is unlikely to occur more than 1 day per month, while the potential for light icing is above 5 days per month in December, January, and February. Icing would be unlikely to occur at any time from April through October.

B.2.4 Hurricanes and Tropical Storms

During the 160 years for which weather records have been kept, ten hurricanes have made landfall in Massachusetts and five others have passed through the Wind Farm Area without making landfall. The latest hurricane that made a direct landfall was Hurricane Bob in 1991. Out of those ten hurricanes, five ranked as Category 1 on the Saffir-Sampson Scale, two were Category 2 hurricanes, and three were Category 3 hurricanes. Since records have been kept, no Category 4 or 5 hurricanes have made landfall in Massachusetts. Of the hurricanes that passed through the Wind Farm Area without making landfall in Massachusetts, one was Category 2, one was Category 1, and three were tropical storms when they passed through the Wind Farm Area (NOAA 2018). The most recent of these storms was Beryl in 2006. The National Oceanic Atmospheric Administration (NOAA) 2019c defines the winds speeds and typical damage associated with each category of hurricane.

In addition to hurricanes, northeasters may occur several times per year in the fall and winter months. Wind gusts during the strongest northeasters can cause similar damage to a Category 1 hurricane, although northeasters typically are larger and last longer than hurricanes.

B.2.5 Mixing Height

The mixing height is the altitude above ground level to which air pollutants vertically disperse. The mixing height affects air quality because it acts as a lid on the height pollutants can reach. Lower mixing heights can allow less air volume for pollutant dispersion and lead to higher ground-level pollutant concentrations than do higher mixing heights. Table B-6 presents atmospheric mixing height data from the nearest measurement locations to the Project area (Nantucket and Chatham, Massachusetts). As shown in the table, the minimum average mixing height is 389 meters (1,276 feet), while the maximum average mixing height is 1,421 meters (4,662 feet).

Table B-6. Representative seasonal mixing height data

Season	Data Hours Included [a]	Average Mixing Height (meters/feet)	
		Nantucket	Chatham
Winter (December, January, February)	Morning: no-precipitation hours	780/2,559	668/2,192
	Morning: all hours	905/2,969	655/2,149
	Afternoon: no-precipitation hours	791/2,595	774/2,539
	Afternoon: all hours	890/2,920	747/2,451

Season	Data Hours Included [a]	Average Mixing Height (meters/feet)	
		Nantucket	Chatham
Spring (March, April, May)	Morning: no-precipitation hours	588/1,929	681/2,234
	Morning: all hours	734/2,408	664/2,178
	Afternoon: no-precipitation hours	746/2,447	1,218/3,996
	Afternoon: all hours	827/2,713	1,110/3,642
Summer (June, July, August)	Morning: no-precipitation hours	389/1,276	569/1,867
	Morning: all hours	448/1,470	568/1,863
	Afternoon: no-precipitation hours	609/1,998	1,421/4,662
	Afternoon: all hours	667/2,188	1,295/4,249
Fall (September, October, November)	Morning: no-precipitation hours	625/2,051	586/1,923
	Morning: all hours	739/2,425	583/1,913
	Afternoon: no-precipitation hours	765/2,510	1,036/3,399
	Afternoon: all hours	831/2,726	945/3,100
Annual Average	Morning: no-precipitation hours	595/1,952	620/2,034
	Morning: all hours	707/2,320	618/2,028
	Afternoon: no-precipitation hours	727/2,385	1,121/3,678
	Afternoon: all hours	804/2,638	1,028/3,373

B.2.6 Potential General Impacts of Offshore Wind Facilities on Meteorological Conditions

A known impact of offshore wind facilities on meteorological conditions is the wake effect. A wind turbine generator (WTG) extracts energy from the free flow of wind, creating turbulence downstream of the WTG. The resulting “wake effect” is the aggregated influence of the WTGs for the entire wind farm on the available wind resource and the energy production potential of any facility located downstream. Christiansen and Hasager (2005) observed offshore wake effects from existing facilities via satellite with synthetic aperture radar to last anywhere from 1.2 to 12.4 miles (2 to 20 kilometers) depending on ambient wind speed, direction, degree of atmospheric stability and the number of turbines within a facility. During stable atmospheric conditions, these offshore wakes can be longer than 43.5 miles (70 kilometers).

Under certain conditions, offshore wind farms also can affect temperature and moisture downwind of the facilities. For example, from September 2016 to October 2017, a study using aircraft observations accompanied by mesoscale simulations examined the spatial dimensions of micrometeorological impacts from a wind energy facility in the North Sea (Siedersleben et al. 2018). Measurements and associated modeling indicated that measurable redistribution of moisture and heat were possible up to 62 miles (100 kilometers) downwind of the wind farm. However, this occurred only when (a) there was a strong, sustained temperature inversion at or below hub height and (b) wind speeds were greater than approximately 13.4 mph (6 meters/second) (Siedersleben et al. 2018). Typically, air temperature will decrease with height above the sea surface in the lower atmosphere (i.e., the troposphere), and air will freely rise and disperse up to the mixing height (Holzworth 1972; Ramaswamy et al. 2006). A temperature inversion occurs when a warmer overlying air mass causes temperatures to increase with height; a strong inversion inhibits the further rise of cooler surface air masses, thus limiting the mixing height (Ramaswamy et al. 2006). Therefore, the North Sea study suggests that rapidly spinning turbines with hub heights at or above a strong inversion may induce mixing between air masses that would otherwise remain separated, which can significantly affect temperature and humidity downwind of a wind farm.

As shown in Table B-6, the minimum average mixing height in the region is much higher than the height of the top of the proposed WTG rotors (780–1,066 feet [238–325 meters]) or the WTG hubs (419–605 feet [128–184 meters]). Therefore, WTG hub heights are expected to remain well below the typical mixing height and associated temperature inversions over the open ocean in the Project region. Accordingly, the redistribution of moisture and heat due to rotor-induced vertical mixing, and any associated shifts to the microclimate, would be limited to the immediate vicinity of the Project.

B.3 Marine Mammals

There are 38 species of marine mammals within the Northwest Atlantic Outer Continental Shelf (OCS) region and 31 that have been documented or are considered likely to occur in the Project area (Table B-7). Species' federal protection status, occurrence in the geographic analysis area and Project area, critical habitat, population size trends, and mortality data must be considered to understand the potential impacts and their magnitude from the Proposed Action, action alternatives, and the No Action Alternative. The West Indian manatee (*Trichechus manatus*) is considered extralimital and rare and is not expected to occur in the Project area; thus, this species is not considered further. In addition, six species within the toothed whales and dolphins group were considered to have "hypothetical" occurrence and were excluded from the assessment of the Proposed Action (BOEM 2014). For an in-depth discussion of marine mammals in the vicinity of the Project area and the analysis of impacts, refer to Chapter 3, Section 3.5.6, *Marine Mammals*.

Table B-7. Marine mammal species documented or likely to occur in the Project area and their stock information

Species	Scientific Name	Stock	Best Population Estimate [a]	Status under MMPA [b]	Status under ESA	Relative Occurrence in Project Region [c]	Population trend [d]	Reference for Population Data
Baleen Whales (Mysticetes)								
Blue whale	*Balaenoptera musculus*	W. North Atlantic	402 [e]	Strategic	Endangered	Rare	Unavailable	Hayes et al. (2020)
Fin whale	*Balaenoptera physalus*	W. North Atlantic	6,802	Strategic	Endangered	Common	Unavailable	Hayes et al. (2021)
Humpback whale	*Megaptera novaeangliae*	Gulf of Maine	1,396	Non-Strategic	Not Listed	Common	+2.8%/year	Hayes et al. (2021)
Minke whale	*Balaenoptera acutorostrata*	Canadian East Coast	21,968	Non-Strategic	–	Common	Unavailable	Hayes et al. (2021)
North Atlantic right whale	*Eubalaena glacialis*	W. North Atlantic	338 [f]	Strategic	Endangered	Common	Decreasing	Hayes et al. (2023)
Sei whale	*Balaenoptera borealis*	Nova Scotia	6,292	Strategic	Endangered	Common	Unavailable	Hayes et al. (2021)
Toothed Whales (Odontocetes)								
Atlantic spotted dolphin	*Stenella frontalis*	W. North Atlantic	39,921	Non-Strategic	–	Rare	Decreasing	Hayes et al. (2020)
Atlantic white-sided dolphin	*Lagenorhynchus acutus*	W. North Atlantic	93,233	Non-Strategic	–	Common	Unavailable	Hayes et al. (2020)
Common bottlenose dolphin	*Tursiops truncatus*	W. North Atlantic, Northern Migratory Coastal	62,851	Strategic	–	Common	Decreasing	Hayes et al. (2021)
Pantropical spotted dolphin	*Stenella attenuata*	W. North Atlantic	6,593	Non-Strategic	–	Rare	Unavailable	Hayes et al. (2020)
Risso's dolphin	*Grampus griseus*	W. North Atlantic	35,215	Non-Strategic	–	Uncommon	Unavailable	Hayes et al. (2020)

Species	Scientific Name	Stock	Best Population Estimate [a]	Status under MMPA [b]	Status under ESA	Relative Occurrence in Project Region [c]	Population trend [d]	Reference for Population Data
Short beaked common dolphin	*Delphinus delphis*	W. North Atlantic	172,974	Non-Strategic	–	Common	Unavailable	Hayes et al. (2021)
Striped dolphin	*Stenella coeruleoalba*	W. North Atlantic	67,036	Non-Strategic	–	Rare	Unavailable	Hayes et al. (2020)
White-beaked dolphin	*Lagenorhynchus albirostris*	W. North Atlantic	536,016	Non-Strategic	–	Rare	Unavailable	Hayes et al. (2020)
Harbor porpoise	*Phocoena phocoena*	Gulf of Maine/Bay of Fundy	95,543	Non-Strategic	–	Common	Unavailable	Hayes et al. (2021)
Blainville's beaked whale	*Mesoplodon densirostris*	W. North Atlantic	10,107 [g]	Non-Strategic	–	Rare	Unavailable	Hayes et al. (2020)
Cuvier's beaked whale	*Ziphius cavirostris*	W. North Atlantic	5,744 [g]	Non-Strategic	–	Rare	Unavailable	Hayes et al. (2020)
Dwarf sperm whale	*Kogia sima*	W. North Atlantic	7,750[h]	Non-Strategic	–	Rare	Increasing [i]	Hayes et al. (2020)
Gervais' beaked whale	*Mesoplodon europaeus*	W. North Atlantic	10,107 [g]	Non-Strategic	–	Rare	Unavailable	Hayes et al. (2020)
Killer whale	*Orcinus orca*	W. North Atlantic	Unknown	Non-Strategic	–	Rare	Unavailable	Waring et al. (2015)
Long-finned pilot whale	*Globicephala melas*	W. North Atlantic	39,215	Non-Strategic	–	Uncommon	Unavailable	Hayes et al. (2020)
Pygmy sperm whale	*Kogia breviceps*	W. North Atlantic	7,750 [h]	Non-Strategic	–	Rare	Increasing [i]	Hayes et al. (2020)
Short-finned pilot whale	*Globicephala macrorhynchus*	W. North Atlantic	28,924	Non-Strategic	–	Rare	Unavailable	Hayes et al. (2020)
Sowerby's beaked whale	*Mesoplodon bidens*	W. North Atlantic	10,107 [g]	Non-Strategic	–	Rare	Unavailable	Hayes et al. (2020)
Sperm whale	*Physeter macrocephalus*	North Atlantic	4,349	Strategic	Endangered	Uncommon	Unavailable	Hayes et al. (2020)
True's beaked whale	*Mesoplodon mirus*	W. North Atlantic	10,107 [g]	Non-Strategic	–	Rare	Unavailable	Hayes et al. (2020)

Species	Scientific Name	Stock	Best Population Estimate [a]	Status under MMPA [b]	Status under ESA	Relative Occurrence in Project Region [c]	Population trend [d]	Reference for Population Data
Earless Seals (Pinnipeds)								
Harbor seals	*Phoca vitulina*	W. North Atlantic	61,336	Non-Strategic	–	Common	Unavailable	Hayes et al. (2021)
Gray seals	*Halichoerus grypus*	W. North Atlantic	27,300	Non-Strategic	–	Common	Increasing	Hayes et al. (2021)
Hooded seals	*Cystophora cristata*	W. North Atlantic	Unknown	Non-Strategic	–	Rare	Unavailable	Hayes et al. (2020)
Harp seal	*Phoca groenlandica*	W. North Atlantic	7.6 million	Non-Strategic	–	Uncommon	Unavailable	Hayes et al. (2020)

[a] Unless otherwise noted, best available abundance estimates are from NMFS stock assessment reports (Hayes et al. 2020, 2021, 2023).
[b] The MMPA defines a "strategic" stock as a marine mammal stock (a) for which the level of direct human-caused mortality exceeds the potential biological removal level; (b) which, based on the best available scientific information, is declining and is likely to be listed as a threatened species under the ESA within the foreseeable future; (c) which is listed as a threatened or endangered species under the ESA; or (d) is designated as depleted.
[c] Data from SouthCoast Wind COP Volume 2.
[d] Increasing = beneficial trend, not quantified; Decreasing = adverse trend, not quantified; Unavailable = population trend analysis not conducted on this species.
[e] The minimum population estimate is reported as the best population estimate in the most recently updated 2021 draft stock assessment report (SouthCoast Wind 2024).
[f] This estimate is based on the 2022 U.S Atlantic and Gulf of Mexico Marine Mammal Stock Assessments (Hayes et al. 2023).
[g] This estimate includes Gervais' beaked whales and Blainville's beaked whales for the Gulf of Mexico stocks, and all species of *Mesoplodon* undifferentiated beaked whales in the Atlantic.
[h] This estimate includes both dwarf and pygmy sperm whales.
i Increasing trend should be interpreted with caution (Hayes et al. 2020)
ESA = Endangered Species Act; MMPA = Marine Mammal Protection Act

B.4 Finfish

There are a variety taxa of state- and federally managed fishes managed finfish within the Northeast Continental Shelf Large Marine Ecosystem that have essential fish habitat (EFH) designated in the Project area (COP Volume 2, Section 6.7.2.2.1, Table 6-49 through Table 6-51; SouthCoast Wind 2024) or recorded catch in (COP Appendix V, Section 2.2, Table 2-5; SouthCoast Wind 2024) or in and around (COP Appendix V, Section 2.1, Table 2-1; SouthCoast Wind 2024) the Project area. These species are listed in Table B-8.

Table B-8. Relevant managed fish taxa in the Northeast Continental Shelf Large Marine Ecosystem

Taxa		
Acadian redfish (*Sebastes fasciatus*)	Albacore tuna (*Thunnus alalunga*)	Coastal and non-coastal sharks (for full list of shark species see COP Volume 2, Section 6.7.2.2.1, Table 6-51; SouthCoast Wind 2024)
American eel (*Anguilla rostrata*)	American plaice (*Hippoglossoides platessoides*)	Goosefish (*Lophius americanus*)
American shad (*Alosa sapidissima*)	Atlantic cod (*Gadus morhua*)	Hickory shad (*Alosa mediocris*)
Atlantic croaker (*Micropogonias undulatus*)	Atlantic halibut (*Hippoglossus hippoglossus*)	Ocean pout (*Macrozoarces americanus*)
Atlantic herring (*Clupea harengus*)	Atlantic mackerel (*Scomber scombrus)*	Pollock (*Pollachius pollachius)*
Atlantic menhaden (*Brevoortia tyrannus)*	Atlantic striped bass (*Morone saxatilis)*	River herring (*Alosa* spp.*)*
Atlantic sturgeon (*Acipenser oxyrinchus)*	Atlantic wolffish (*Anarhichas lupus)*	Scup (*Stenotomus chrysops)*
Barndoor skate (*Dipturus laevis*)	Black sea bass (*Centropristis striata*)	Cobia (*Rachycentron canadum*)
Bluefin tuna (*Thunnus thynnus*)	Bluefish (*Pomatomus saltatrix*)	Haddock (*Melanogrammus aeglefinus*)
Butterfish (*Peprilus triacanthus*)	Clearnose skate (*Raja eglanteria*)	Little skate (*Leucoraja erinacea*)
Skipjack tuna (*Katsuwonus pelamis)*	Smooth skate (*Mustelus canis)*	Offshore hake *(Merluccius albidus)*
Spanish mackerel (*Scomberomorus maculatus)*	Spiny dogfish (*Squalus acanthias)*	Red hake *(Urophycis chuss)*
Spot (*Leiostomus xanthurus)*	Summer flounder (*Paralichthys dentatus*)	Rosette skate (*Leucoraja garmani*)
Swordfish (*Xiphias gladius)*	Tautog (*Tautoga onitis*)	Silver hake (*Merluccius bilinearis)*
Thorny skate	Tilefish	Witch flounder

Taxa		
(Amblyraja radiata)	(*Caulolatilus microps and Lopholatilus chamaelonticeps)*	*(Glyptocephalus cynoglossus)*
Weakfish (*Cynoscion regalis*)	White hake (*Urophycis tenuis*)	Winter flounder (*Pseudopleuronectes americanus*)
White marlin (*Tetrapturus albidus)*	Windowpane (*Scopthalmus aquosus)*	Winter skate (*Leucoraja ocellata*)

B.5 Environmental Justice

The U.S. Census tracts with environmental justice communities in the geographic analysis area, as described in Section 3.6.4, *Environmental Justice*, are presented in the following tables. Table B-9 presents the tracts for Massachusetts based on Massachusetts Executive Office of Energy and Environmental Affairs data. Table B-10 presents the tracts for Rhode Island, Connecticut, Maryland, South Carolina, and Texas based on U.S. Environmental Protect Agency's Environmental Justice Screening and Mapping Tool's data.

Table B-9. U.S. census tracts with environmental justice populations in Massachusetts

B.6 Water Quality

SouthCoast Wind filed a National Pollutant Discharge Elimination System (NPDES) permit application for the high voltage direct current (HVDC) converter offshore substation platform (OSP) for Project 1 in October 2022 and revised applications on December 12, 2022, April 10, 2023, and August 25, 2023 (TetraTech and Normandeau Associates, Inc. 2023). An overview of the characteristics of the cooling water intake structure (CWIS) in the HVDC converter OSP is provided in Table B-11. Figure B-2 shows the indicative location of the HVDC converter OSP for Project 1. Figures B-3 to B-6 depict results of the modeled scenarios with the maximum seasonal temperature delta between ambient and thermal effluent during four seasons (Scenario 1: fall, Scenario 2: winter, Scenario 3: spring, and Scenario 4: summer) at the outfall location.

Table B-11. Characteristics of one SouthCoast Wind HVDC converter OSP

Configuration Parameter	SouthCoast Wind HVDC Converter OSP
Water Source	Atlantic Ocean
Cooling Water Intake System (CWIS)	Non-contact, once-through cooling. Each of the three intakes pipes (caissons) operates independently with its own seawater lift pump. No common entrance or shared piping between each intake caisson. Typical operations utilize no more than two seawater lift pumps, with the third serving only as a backup to the other two pumps (no operating scenario will utilize three seawater lift pumps simultaneously).

Configuration Parameter	SouthCoast Wind HVDC Converter OSP
Configuration of intake	Three, approximately 28-inch (0.7-m)-diameter vertical-shaft intake caissons, with flared ends to accommodate intake velocity requirements, set perpendicular to the seafloor, in the middle portion of the water column, located within the jacketed foundation structure. The discharge is in the middle portion of the water column. They are separated so that heated discharge is not withdrawn into the intake. The three intake caissons on the OSP are separated by approximately 3.3 feet (1 meter) distance from each other, with the first caisson located approximately 91.9 feet (28 meters) distance from the center of the platform coordinates. Note that the three intake caissons are independently operating structures with no common intake or entrance.
Configuration of discharge	The cooling water discharge includes one 36-inch (0.91-meter)-diameter vertical-shaft discharge caisson, located in the middle portion of the water column, and set perpendicular to the seafloor, located within the jacketed foundation structure. The discharge depth is 42.7 feet (13 meters) below the surface and the location of discharge is within a 20-meter radius from the center of the platform coordinates. This location/depth ensures sufficient distance is maintained between the lift pump caisson and the overboard water caisson.
Trash/debris bar rack	The intake caisson(s) will be equipped with a stainless steel trash or debris bar rack. The bar rack will consist of stainless steel bars approximately 0.8 inch (20 millimeters) wide, or similar, fixed to the bell mouth opening of the intake caisson. SouthCoast Wind will require the bar rack to be incorporated into the specific design elements of the OSP fabricator. However, the use of trash or debris bar racks is not optimal for a seawater lift pump caisson installed in an offshore environment. The use of a bar rack at the intake of the pump caisson will create maintenance concerns over time; the bar rack will biofoul with encrusting/fouling organisms and will require direct access to the pump caisson intake periodically for cleaning campaigns. The original design did not include a bar rack for this reason, but a bar rack will be added for compliance requirements of the NPDES permit application. SouthCoast Wind is considering a distance of 5 inches (12.7 cm) spacing between bars. The configuration details will be refined during the detailed design stage, which will include consultations with USEPA and other agencies to ensure appropriate spacing of bars is protective of marine organisms, as applicable within engineering constraints (e.g., flow velocity, biofouling).
Pump screens/strainers	Each seawater intake caisson is equipped with an in-built pump strainer with a typical outer screen size of 3/8 inch (9.5 millimeters), intended to protect the seawater lift pump impeller from debris in the water column. The strainers are retractable on the seawater lift pump for cleaning. At deck level 1 of the OSP, each pump flowline is also equipped with a dedicated filter (typical mesh size of 250 micrometers), intended to protect the equipment and ensure reliable operation of the CWIS. The filter is provided with an automated backwash cleaning system. No chemicals are involved in the cleaning cycles.
Number of traveling screens/ screen wells	N/A – no traveling screens
Water depth of withdrawal, below surface at MLLW	Proposed 74 feet (22.6 meters) below the water surface at MLLW and contingent on NPDES permit requirements.

Configuration Parameter	SouthCoast Wind HVDC Converter OSP
Water depth of withdrawal, above seafloor	Proposed 81 feet (24.7 meters) above seafloor and contingent on NPDES permit requirements.
Through-screen velocity (calculated from Design Intake Flow [DIF])	**Intake velocity will not exceed 0.5 feet (0.2 meters) per second** to meet the velocity-based impingement compliance option. A maximum velocity of less than or equal to 0.5 feet (0.2 meters) per second will be integrated into the engineering design of the CWIS to ensure compliance. The intake velocity of 0.5 feet (0.2 meters) per second (or less) will be ensured to be the design limit velocity at the bar rack, accomplished by ensuring the CWIS intake bell mouth diameter is sized in relation to the lift pump maximum flow rate (i.e., determined at the maximum power of the motor driving the pump or the pump curve, whichever is greater) and that the bell mouth face velocity is not exceeding 0.5 feet (0.2 meters) per second. See NPDES permit application Section 6.2 (Tetratech and Normandeau Associates Inc., 2023) for intake velocity calculation, based on parameters below, including pump data from a submersible seawater lift pump deployed on another project with a similar cooling duty requirement of 50.16 Btu/h (14.7 megawatts): • Maximum cooling seawater flow required DIF: 9.9 MGD (2 x 780 m^3/h = 1,560 m^3/h), including contingency • Selected pump maximum operational flow (Qmax): (780 m^3/h), based on representative pump data • CWIS intake bell mouth diameter: 4.74 ft (1.445 m) • CWIS intake bell mouth area: 17.66 ft^2 (1.64 m^2) • CWIS intake velocity (face velocity): < 0.5 ft/s (0.15 m/s) • Cross-sectional open area of caisson inlet = 17.65 ft^2 (1.640 m^2), adjusted for the area occupied by the bar rack (0.936 ft^2 [0.087 m^2]) = 16.72 ft^2 [1.553 m^2])
Seawater lift pumps (intake pumps)	The seawater cooling system is a once-through (open loop) system. The maximum heat duty of the offshore substation platform (OSP) is 50.16 Btu/h (14.7 MW). This maximum heat duty of 50.16 Btu/h (14.7 MW) requires a maximum seawater flow of 9.9 MGD (i.e.,1,560 m3/h, including contingency) for cooling. Up to two raw seawater vertical lift pumps are required to fulfill the cooling duty. Each seawater lift pump has a rated maximum nameplate flow capacity of 900 cubic meters per hour, but maximum operational flow would not exceed 780 cubic meters per hour per pump, resulting in a maximum design intake flow (DIF) of 9.9 MGD, with two pumps operating. Only two of the three pumps would be used under normal operating conditions, with the third pump only serving as a spare/backup. Each seawater lift pump supplies once-through, non-contact cooling water to a plate heat exchanger, to facilitate heat exchange/cooling with the seawater cooling system (of 7.35 megawatt heat duty capacity per heat exchanger). Internal cooling flow is controlled with the use of a 3-way valve while maintaining a constant speed with seawater once-through (open loop) cooling. In addition, a variable frequency drive (VFD) on each of the seawater lift pump motors, to accomplish the following: 1. The seawater lift pumps are equipped with VFDs for slow start-up of the seawater supply lines. 2. Fine-scale control of the flow volume, based on cooling requirements.

Configuration Parameter	SouthCoast Wind HVDC Converter OSP
	3. In order to prevent freezing of the standby line, a VFD is used to operate the standby seawater lift pump at minimum flow capacity during the winter season (still within the maximum 9.9 MGD DIF for the facility)
Maximum Discharge Temperature	**86°F (30°C)**
Total DIF	**9.9 MGD** = maximum design intake flow required for cooling of the OSP. Two of the seawater lift pumps operating at approximately 87% of their rated nameplate capacity will provide up to 9.9 MGD (DIF) during normal operating conditions (up to 4.95 MGD each to supply the required cooling water. During normal operating conditions, each individual seawater lift pump will provide up to 4.95 MGD to ensure reliable, safe operating conditions at the unmanned OSP. Seawater Lift Pump settings can be controlled with or without variable frequency drive. Internal cooling flow is controlled by use of a 3-way valve while maintaining a constant speed with the seawater once-through (open loop cooling). The system is designed for a rated nameplate capacity of each seawater lift pump of 900 m^3/h. However, SouthCoast Wind is seeking 9.9 MGD maximum design intake flow (DIF) in the NPDES permit to align with the expected maximum operational conditions (two pumps operating at up to 780 m^3/h each), as the seawater lift pumps are not designed to operate at 100% of their total rated nameplate capacity to meet the cooling needs of the OSP.
Flow Reduction from Design Capacity	While 9.9 MGD is the DIF, a 50% flow reduction potential from DIF could be achieved by use of single-pump operation (4.95 MGD), or dual-pumps each operating at reduced capacity during low-load operating conditions.
Closed-cycle recirculating cooling	None. Closed-cycle (closed-loop) cooling using air or seawater is not an available technology for SouthCoast – Project 1.
Monitoring parameters and sensor locations	The three intake structures will include the following instrumentation: • Temperature & water conductivity monitoring devices installed at the seawater lift pump intake. • The intake seawater flowline has an inline flow meter installed upstream of the seawater filter at the topside of the converter station. • Temperature and flow monitoring devices are installed at the feed line and at the discharge outlet of the seawater heat exchanger. Mechanical sampling connections located at the return line of seawater.
Chlorination System	The CWIS is equipped with an antifouling system to prevent marine growth in the pump caissons and the Seawater System, which consists of Hypochlorite Generator Packages. The Hypochlorite Generator Packages produces Sodium Hypochlorite (NaOCl) by seawater electrolysis. The hypochlorite is injected into the pump caissons near the suction level of the Seawater Lift Pumps. Hypochlorite Generator Packages are designed to achieve a hypochlorite solution flow rate of sufficient concentration, corresponding with a 1 to 4 ppm equivalent free chlorine concentration in the seawater intake lines. This method of continuous injection into the pump caisson is preferred because at a low dosage of NaOCl (i.e., 2 mg/l, 95 kg/day), the residual free chlorine at the outlet would be negligible and oxidized in the water with no negative impact.

Appendix C: Project Design Envelope and Maximum-Case Scenario

SouthCoast Wind Energy LLC (SouthCoast Wind) would implement a Project Design Envelope (PDE) concept. This concept allows SouthCoast Wind to define and bracket proposed project characteristics for environmental review and permitting while maintaining a reasonable degree of flexibility for selection and purchase of project components such as wind turbine generators (WTGs), foundations, submarine cables, and offshore substation platforms (OSPs).

The Bureau of Ocean Energy Management (BOEM) invited SouthCoast Wind and other lessees to submit construction and operations plans (COPs) using the PDE concept—providing sufficiently detailed information within a reasonable range of parameters to analyze a “maximum-case scenario” within those parameters for each affected environmental resource. BOEM identified and verified that the maximum-case scenario based on the PDE provided by SouthCoast Wind and analyzed in this Environmental Impact Statement (EIS) could reasonably occur if approved. This approach is intended to provide flexibility for lessees and allow BOEM to analyze environmental impacts in a manner that minimizes the need for subsequent environmental and technical reviews. In addition, the PDE approach may enable BOEM to expedite review by beginning National Environmental Policy Act (NEPA) evaluations of COPs before a lessee has finalized all its design decisions.

This EIS assesses the impacts of the reasonable range of project designs that are described in the SouthCoast Wind COP by using the “maximum-case scenario” process. The maximum-case scenario analyzes the aspects of each design parameter that would result in the greatest impact for each physical, biological, and socioeconomic resource. This Final EIS considers the interrelationship between aspects of the PDE rather than simply viewing each design parameter independently. This EIS also analyzes the planned action impacts of the maximum-case scenario alongside other reasonably foreseeable past, present, and future actions.

Certain resources evaluated in this EIS may have multiple maximum-case scenarios, and the most impactful design parameters may not be the same for all resources. A summary of SouthCoast Wind’s PDE parameters is provided in Table C-1. Table C-2 details the full range of maximum-case design parameters for the proposed Project and which parameters are relevant to the analysis for each EIS Section in Chapter 3, *Affected Environment and Environmental Consequences*.

Table C-1. Summary of PDE parameters

Project Parameter Details
General (Layout and Project Size)
• Up to 147 WTGs • Up to 5 OSPs • Up to a total of 149 WTG/OSP positions • 1 nautical mile (nm) x 1 nm (1.9 kilometers x 1.9 kilometers) grid layout with east–west and north–south orientation • Project to be developed in two parts or projects: Project 1 refers to the development in the northern portion of the Lease Area and associated interconnection, and Project 2 refers to the development in the southern portion of the Lease Area and associated interconnection.
Foundations
• Monopile, piled jacket, and/or suction-bucket jacket (maximum 85 suction-bucket jacket foundations for Project 2) • Scour protection for up to all foundations • Seabed penetration up to 262.4 feet (80 meters) depth • Foundation piles would be installed using a pile-driving hammer and/or drilling techniques such as using a hydraulic impact hammer, vibratory hammer, or water jetting
Wind Turbine Generators
• Rotor diameter up to 918.6 feet (280 meters) • Blade length up to 452.8 feet (138 meters) • Hub height up to 605.1 feet (184.4 meters) above mean lower low water (MLLW) • Upper blade tip height up to 1,066.3 feet (325 meters) above MLLW • Lowest blade tip height (air gap) 75.5 feet (23 meters) above highest astronomical tide
Offshore Substation Platforms
• Up to five OSPs • OSPs installed atop a monopile, piled jacket, and/or suction-bucket jacket • OSPs may use high voltage direct current (HVDC) or high voltage alternating current (HVAC) technology • Total OSP structure height up to 344.5 feet (105 meters) above MLLW • Scour protection for all foundations • Maximum length and width of topside structure 360.9 feet by 328.1 feet (110 meters by 100 meters; with ancillary facilities) • Foundation piles to be installed using a pile-driving hammer and/or drilling techniques such as using a hydraulic impact hammer, vibratory hammer, or water jetting. • Each HVDC converter OSP will use less than 10 million gallons per day of once-through non-contact cooling water and a maximum end-of-pipe discharge temperature of 86°F (30°C)
Interarray Cables
• Anticipated burial depth of 3.2 to 8.2 feet (1 to 2.5 meters) • Nominal interarray cable voltage: 60 kilovolt (kV) to 72.5 kV • Maximum interarray cable diameter of 1.24 inches (800 millimeter) • Maximum total interarray cable length is 497.1 miles (800 kilometers) • Preliminary layout available; however, final layout pending • Cable lay, installation, and burial: Activities may involve use of a jetting remotely operated vessel (ROV), mechanical cutting ROV system, plowing (pre-cut and mechanical)

Project Parameter Details
Falmouth Offshore Export Cables [a]
• Up to 5 offshore export cables (4 power cables and 1 communications cable) • Nominal export cable voltage: 200 kV to 345 kV HVAC or ±525 kV HVDC • Maximum total export cable corridor length is 87 miles (140 kilometers) • Maximum export cable length is 434.9 miles (700 kilometers • Anticipated burial depth of 3.2 to 13.1 feet (1 to 4 meters); target burial depth of 6 feet (1.8 meters) • Up to 9 cable / pipeline crossings • Cable lay, installation, and burial: Activities may involve use of a jetting tool (jetting ROV or jetting sled), vertical injection, mechanical cutting ROV system, plowing (pre-cut and mechanical)
Brayton Point Offshore Export Cables
• Up to 6 offshore export cables (2 cable bundles consisting of 2 power cables and 1 communications cable per bundle) • Nominal export cable voltage: ±320 kV HVDC • Maximum total export cable corridor length is 124 miles (200 kilometers) • Maximum export cable length is 744 miles (1,200 kilometers) • Anticipated burial depth of 3.2 to 13.1 feet (1 to 4 meters); target burial depth of 6 feet (1.8 meters) • Up to 16 cable/pipeline crossings • Cable lay, installation, and burial: Activities may involve use of a jetting tool (jetting ROV or jetting sled), vertical injection, mechanical cutting ROV system, plowing (pre-cut and mechanical)
Falmouth Landfall Site [a]
• Three landfall locations under consideration: Worcester Avenue (preferred), Central Park, and Shore Street
Brayton Point Landfall Site
• Two landfall locations under consideration: the western (preferred) and eastern (alternate) shorelines of Brayton Point • Aquidneck Island, Portsmouth, Rhode Island; several locations under consideration for intermediate landfall across the island
Falmouth Onshore Export Cable Corridor[a]
• Up to 12 onshore export cables and up to five communications cables • Nominal underground onshore export cable voltage: 200 kV to 345 kV HVAC • Maximum onshore export cable length is 6.4 statute miles (10.3 kilometers)
Brayton Point Onshore Export Cable Corridor
• Up to 6 onshore export cables and up to two communications cables • Nominal underground onshore export cable voltage: ±320 kV HVDC • Maximum onshore export cable length is 0.7 mile (1.1 kilometer)
Brayton Point Onshore Export Cable Corridor on Aquidneck Island (intermediate landfall)
• Up to 4 onshore export cables and up to two communications cables • Nominal underground onshore export cable voltage: ±320 kV HVDC • Onshore export cable corridor length is 3 miles (4.8 kilometers) across Aquidneck Island

Project Parameter Details
Falmouth Onshore Substation/Interconnection [a]
• Two Falmouth locations under consideration - Lawrence Lynch (preferred) and Cape Cod Aggregates (alternate) • Up to 26 acres (10.5 hectares) permanent area • New 345-kV overhead (preferred) or underground (alternate) transmission line in existing right-of-way up to 2.1 miles (3.4 kilometers) in length • Transmission line to Falmouth point of interconnection would be designed, permitted, and constructed by interconnection transmission owner
Brayton Point Converter Station/Interconnection
• One Brayton Point location under consideration – existing National Grid substation • Up to two new HVDC converter stations • Up to 7.5 acres (3 hectares) permanent area for each converter station • New 345-kV underground transmission route to existing Brayton Point point of interconnection, up to 0.2 mile (0.3 kilometer) on Brayton Point property

[a] To be developed only if Falmouth is the selected point of interconnection for Project 2.

OSP Suction-Bucket Jacket (COP Volume 1 Table 3-3)																				
Number of OSPs	Up to 5	X	X	X	X	X		X	X	X		X	X	X	X	X	X	X	X	X
Diameter of suction bucket at seabed (seabed centerline diameter)	180.4 feet (55.0 meters)				X			X	X	X		X	X				X		X	
Foundation diameter (pile or bucket diameter at mudline)	65.6 feet (20.0 meters)				X			X	X	X		X	X				X		X	
Number of legs/discrete contact points with seabed per substructure	Up to 4 foundations and 1 bucket per foundation				X			X	X	X		X	X				X		X	
Depth of penetration below seabed with scour protection	65.6 feet (20.0 meters)				X			X	X	X		X	X				X		X	
Distance between adjacent legs at seabed	65.6 feet (20.0 meters)				X			X	X	X		X	X				X		X	
Total foundation footprint contacting seabed per foundation [a]	4.90 acres (1.98 hectares)				X			X	X	X		X	X				X		X	

Design Parameter	Maximum Design Parameters	3.4.1 Air Quality	3.4.2 Water Quality	3.5.1 Bats	3.5.2 Benthic Resources	3.5.3 Birds	3.5.4 Coastal Habitat and Fauna	3.5.5 Finfish, Invertebrates, and Essential Fish Habitat	3.5.6 Marine Mammals	3.5.7 Sea Turtles	3.5.8 Wetlands and Other Waters of the United States	3.6.1 Commercial Fisheries and For-Hire Recreational Fishing	3.6.2 Cultural Resources	3.6.3 Demographics, Employment, and Economics	3.6.4 Environmental Justice	3.6.5 Land Use and Coastal Infrastructure	3.6.6 Navigation and Vessel Traffic	3.6.7 Other Uses (Marine Minerals, Military Use, Aviation, Scientific Research, and Surveys)	3.6.8 Recreation and Tourism	3.6.9 Visual Resources
PARAMETERS PER OSP FOUNDATION STRUCTURE (COP Volume 1 Table 3-3) – Option B Integrated																				
OSP Pin-Pile Jacket (COP Volume 1 Table 3-3)																				
Number of OSPs	Up to 5	X	X	X	X	X		X	X	X		X	X	X	X	X	X	X	X	X
Diameter at seabed (seabed centerline diameter)	213 feet x 105 feet (65 meters x 32 meters)				X			X	X	X		X	X				X		X	
Foundation diameter (pile or bucket diameter at mudline)	11.7 feet (3.57 meters)				X			X	X	X		X	X				X		X	
Number of legs/discrete contact points with seabed per substructure	Up to 6 foundations and up to 3 piles per foundation				X			X	X	X		X	X				X		X	
Depth of penetration below seabed with scour protection	277.2 feet (84.5 meters)				X			X	X	X		X	X				X		X	
Foundation diameter/leg spacing at mean sea level (MSL)	114.8–168.0 feet (35–50 meters				X			X	X	X		X	X				X		X	
Total foundation footprint contacting seabed per foundation [a]	7.54 acres (3.05 hectares)				X			X	X	X		X	X				X		X	
PARAMETERS PER OSP FOUNDATION STRUCTURE (COP Volume 1 Table 3-3) – Option C DC Converter																				
OSP Pin-Pile Jacket (COP Volume 1 Table 3-3)																				
Number of OSPs	Up to 5	X	X	X	X	X		X	X	X		X	X	X	X	X	X	X	X	X
Diameter at seabed (seabed centerline diameter)	279 feet x 197 feet (85 meters x 60 meters)				X			X	X	X		X	X				X		X	
Foundation diameter (pile or bucket diameter at mudline)	12.8 feet (3.9 meters)				X			X	X	X		X	X				X		X	
Number of legs/discrete contact points with seabed	4 foundations and 1 to 4 piles / foundation = 4 to 16 piles				X			X	X	X		X	X				X		X	
Depth of penetration below seabed with scour protection	262.4 feet (80 meters)				X			X	X	X		X	X				X		X	
Total foundation footprint contacting seabed per foundation [a]	9.79 acres (3.96 hectares)				X			X	X	X		X	X				X		X	
PERMANENT SEABED DISTURBANCE (COP Volume 1 Table 3-36; Table 3-37)																				
Monopile WTG Substructures (COP Volume 1 Table 3-37)																				
Total permanent footprint per foundation [a]	2.52 acres (1.02 hectares)		X		X			X	X	X		X	X				X		X	
Total permanent footprint for 147 WTG foundations [a]	370.44 acres (149.94 hectares)		X		X			X	X	X		X	X				X		X	
Pin-Pile Jacket WTG Substructures (COP Volume 1 Table 3-37)																				
Total permanent footprint per foundation [a]	2.61 acres (1.05 hectares)		X		X			X	X	X		X	X				X		X	
Total permanent footprint for 147 WTG foundations [a]	383.67 acres (154.35 hectares)		X		X			X	X	X		X	X				X		X	
Pin-Pile Jacket OSP Substructures (COP Volume 1 Table 3-36)																				
Total permanent footprint per OSP foundation [a]	9.8 acres (3.7 hectares)		X		X			X	X	X		X	X				X		X	
Total permanent footprint for 2 OSP foundations [a]	19.6 acres (7.4 hectares)		X		X			X	X	X		X	X				X		X	

Design Parameter	Maximum Design Parameters	3.4.1 Air Quality	3.4.2 Water Quality	3.5.1 Bats	3.5.2 Benthic Resources	3.5.3 Birds	3.5.4 Coastal Habitat and Fauna	3.5.5 Finfish, Invertebrates, and Essential Fish Habitat	3.5.6 Marine Mammals	3.5.7 Sea Turtles	3.5.8 Wetlands and Other Waters of the United States	3.6.1 Commercial Fisheries and For-Hire Recreational Fishing	3.6.2 Cultural Resources	3.6.3 Demographics, Employment, and Economics	3.6.4 Environmental Justice	3.6.5 Land Use and Coastal Infrastructure	3.6.6 Navigation and Vessel Traffic	3.6.7 Other Uses (Marine Minerals, Military Use, Aviation, Scientific Research, and Surveys)	3.6.8 Recreation and Tourism	3.6.9 Visual Resources
Suction Bucket Jacket WTG Substructures (COP Volume 1 Table 3-37)																				
Total permanent footprint per foundation [a]	4.90 acres (1.98 hectares)		X		X			X	X	X		X	X				X		X	
Total permanent footprint for 147 WTG foundations (assumes 85 suction-bucket jacket substructures [maximum considered under the Proposed Action] and pin-pile jackets for the remaining 62 WTG positions) [a]	578.32 acres (233.4 hectares)		X		X			X	X	X		X	X				X		X	
TEMPORARY SEABED DISTURBANCE DURING CONSTRUCTION																				
Monopile WTG Substructures (COP Volume 1 Table 3-37; Table 3-38)																				
Disturbance due to jack-up or anchored vessels per foundation	2.96 acres (1.2 hectares)		X		X			X	X	X		X	X				X		X	
Total temporary seabed disturbance beyond permanent footprint per foundation	0.5 acre (0.2 hectare)		X		X			X	X	X		X	X				X		X	
Total temporary seabed disturbance beyond permanent footprint for 147 WTG foundations	73.5 acres (29.4 hectares)		X		X			X	X	X		X	X				X		X	
Pin-Pile Jacket WTG Substructures (Table 3-37; Table 3-38)																				
Disturbance due to jack-up or anchored vessels per foundation	2.96 acres (1.2 hectares)		X		X			X	X	X		X	X				X		X	
Total temporary seabed disturbance beyond permanent footprint per foundation	0.5 acre (0.2 hectare)		X		X			X	X	X		X	X				X		X	
Total temporary seabed disturbance beyond permanent footprint for 147 WTG foundations	73.5 acres (29.4 hectares)		X		X			X	X	X		X	X				X		X	
Pin-Pile Jacket OSP Substructures (COP Volume 1 Table 3-36; Table 3-38)																				
Disturbance due to jack-up or anchored vessels per foundation	2.96 acres (1.2 hectares)		X		X			X	X	X		X	X				X		X	
Total temporary seabed disturbance beyond permanent footprint per foundation	0.5 acre (0.2 hectare)		X		X			X	X	X		X	X				X		X	
Total temporary seabed disturbance beyond permanent footprint for 2 OSP foundations	1.0 acres (0.4 hectare)		X		X			X	X	X		X	X				X		X	
Suction Bucket Jacket WTG Substructures (COP Volume 1 Table 3-37; Table 3-38)																				
Disturbance due to jack-up or anchored vessels per foundation	2.96 acres (1.2 hectares)		X		X			X	X	X		X	X				X		X	
Total temporary seabed disturbance beyond permanent footprint per foundation	0.6 acre (0.3 hectare)		X		X			X	X	X		X	X				X		X	
Total temporary seabed disturbance beyond permanent footprint for 147 WTG foundations (assumes 85 suction-bucket jacket substructures [maximum considered under the Proposed Action] and pin-pile jackets for the remaining 62 WTG positions)	82 acres (37.9 hectares)		X		X			X	X	X		X	X				X		X	
Installation Timeframe																				
Monopile																				
Approximate duration per foundation	4 hours	X	X	X	X	X		X	X	X		X					X		X	
Number of piles driven per day	2	X	X	X	X	X		X	X	X		X					X		X	

Design Parameter	Maximum Design Parameters	3.4.1 Air Quality	3.4.2 Water Quality	3.5.1 Bats	3.5.2 Benthic Resources	3.5.3 Birds	3.5.4 Coastal Habitat and Fauna	3.5.5 Finfish, Invertebrates, and Essential Fish Habitat	3.5.6 Marine Mammals	3.5.7 Sea Turtles	3.5.8 Wetlands and Other Waters of the United States	3.6.1 Commercial Fisheries and For-Hire Recreational Fishing	3.6.2 Cultural Resources	3.6.3 Demographics, Employment, and Economics	3.6.4 Environmental Justice	3.6.5 Land Use and Coastal Infrastructure	3.6.6 Navigation and Vessel Traffic	3.6.7 Other Uses (Marine Minerals, Military Use, Aviation, Scientific Research, and Surveys)	3.6.8 Recreation and Tourism	3.6.9 Visual Resources
Piled Jacket																				
Approximate duration per foundation	2 hours	X	X	X	X	X		X	X	X		X					X		X	
Number of piles driven per day	8	X	X	X	X	X		X	X	X		X					X		X	
Temporary Seabed Disturbance During WTG Construction (COP Volume 1 Table 3-37; Table 3-38)																				
Area of seabed preparation per foundation monopile	0.5 acre (0.2 hectare)		X		X			X	X	X		X	X				X		X	
Area of seabed preparation per foundation pin-pile jacket	0.5 acre (0.2 hectare)		X		X			X	X	X		X	X				X		X	
Area of seabed preparation per foundation suction-bucket jacket	0.6 acre (0.3 hectare)		X		X			X	X	X		X	X				X		X	
Area of disturbance per jack-up vessel (vessel spuds including all legs)	0.37 acre (0.15 hectare)		X		X			X	X	X		X	X				X		X	
Number of vessel visits per WTG location	6 to 8	X	X		X			X	X	X		X	X	X	X		X		X	
Temporary Seabed Disturbance During OSP Construction (COP Volume 1 Table 3-36; Table 3-38)																				
Area of seabed preparation per foundation pin-pile jacket	0.5 acre (0.2 hectare)		X		X			X	X	X		X	X				X		X	
Number of vessel visits per OSP location	4	X	X		X			X	X	X		X	X	X	X		X		X	
Temporary Seabed Disturbance During WTG/OSP Construction (COP Volume 1 Table 3-38)																				
Total jack-up vessel spud seabed footprint area (149 WTG/OSP locations)	441.8 acres (178.8 hectares)		X		X			X	X	X		X	X				X		X	
INTERARRAY and EXPORT CABLES																				
Interarray Cable (COP Volume 1 Table 3-12; Table 3-30)																				
Cable diameter	1.24 inches (800 millimeter)		X		X	X		X	X	X		X	X				X	X		
Nominal cable voltage (AC)	72.5 kV				X			X	X	X										
Number of WTGs per interarray cable string	1 to up to 9				X								X	X			X	X		
Seabed preparation (assumes local boulder removal and grapnel run over entire length; sand wave and boulder field clearance is not expected in the Lease Area in preparation for interarray cable installation)	99 acres (40 hectares)		X		X	X		X	X	X		X	X	X		X	X			
Cable installation (assumed 19.7 feet [6 meters] of surface impact around each cable)	1,186 acres (480 hectares)		X		X	X		X	X	X		X	X	X		X	X			
Cable protection (assumes mattresses or rock placement at cable crossings and as needed; assumes 10 percent of the interarray cable will require additional protection; a 19.7-foot (6-meter)-wide rock berm would be constructed along these cable sections)	122 acres (50 hectares)		X		X	X						X	X	X			X	X	X	
Total area disturbed	1,408 acres (570 hectares)		X		X	X		X	X	X		X	X	X		X	X		X	
Interarray cable length	497.1 miles (800 kilometers)	X			X	X		X	X	X		X	X	X			X	X	X	
Target burial depth	8.2 feet (2.5 meters)				X	X		X	X	X		X	X				X	X	X	
Number of cable/pipeline crossings	Up to 10				X													X		

Design Parameter	Maximum Design Parameters	3.4.1 Air Quality	3.4.2 Water Quality	3.5.1 Bats	3.5.2 Benthic Resources	3.5.3 Birds	3.5.4 Coastal Habitat and Fauna	3.5.5 Finfish, Invertebrates, and Essential Fish Habitat	3.5.6 Marine Mammals	3.5.7 Sea Turtles	3.5.8 Wetlands and Other Waters of the United States	3.6.1 Commercial Fisheries and For-Hire Recreational Fishing	3.6.2 Cultural Resources	3.6.3 Demographics, Employment, and Economics	3.6.4 Environmental Justice	3.6.5 Land Use and Coastal Infrastructure	3.6.6 Navigation and Vessel Traffic	3.6.7 Other Uses (Marine Minerals, Military Use, Aviation, Scientific Research, and Surveys)	3.6.8 Recreation and Tourism	3.6.9 Visual Resources
Offshore Export Cable (COP Volume 1 Table 3-29; Table 3-14) – Falmouth [b]																				
Number of export cables	Up to 5	X	X		X	X		X	X	X		X	X	X		X	X	X	X	
Nominal cable voltage	345 kV (HVAC) ±525 kV (HVDC)				X			X	X	X										
Burial depth	13.1 feet (4 meters)				X	X		X	X	X		X	X				X	X	X	
Export cable diameter (excluding cable protection)	13.8 inches (350.0 millimeters)		X		X	X		X	X	X		X	X				X	X		
Maximum Length of export cable	434.9 miles (700 kilometers)	X	X		X	X		X	X	X		X	X				X	X		
Length of Offshore cable corridor	87.0 miles (140 kilometers)		X		X	X		X	X	X		X	X				X	X		
Export cable corridor width	3,280.8 feet (1,000 meters)		X		X	X		X	X	X		X	X				X	X		
Number of cable/pipeline crossings (COP Volume 1 Table 3-15)	Up to 9				X													X		
Typical separation distance of export cable	328 feet (100 meters)		X		X	X						X	X				X	X		
Seabed preparation (per cable) (assumes suction hopper dredger over 5 percent of route; boulder field clearance 10 percent of route; grapnel run over the entire route)	138 acres (56 hectares)		X		X	X		X	X	X		X	X	X		X	X			
Cable installation (per cable) (assumes surface impact of 19.7 feet [6 meters] around each cable)	186 acres (75 hectares)		X		X	X		X	X	X		X	X	X		X	X			
Cable protection (per cable) (an estimated 10 percent of the route will require additional cable protection. It is assumed that a 19.7 foot- (6 meter)-wide rock berm will be constructed)	27 acres (11 hectares)		X		X	X		X	X	X		X	X	X		X	X			
Total seabed disturbance area (per cable)	351 acres (142 hectares)		X		X	X		X	X	X		X	X	X		X	X		X	
Total seabed disturbance area (5 cables)	1,753 acres (709 hectares)		X		X	X		X	X	X		X	X	X		X	X		X	
Offshore Export Cable (COP Volume 1 Table 3-29; Table 3-14) – Brayton Point																				
Number of export cable bundles (each bundle consisting of two power cables and one communication cable)	Up to 2	X	X		X	X		X	X	X		X	X	X		X	X	X	X	
Nominal cable voltage (HVDC)	±320 kV				X			X	X	X										
Export cable diameter (excluding cable protection)	6.9 inches (175.0 millimeters)		X		X	X		X	X	X		X	X				X	X		
Burial depth	13.1 feet (4 meters)				X	X		X	X	X		X	X				X	X	X	
Maximum length of export cable	744 miles (1,200 kilometers)	X	X		X	X		X	X	X		X	X				X	X		
Length of Offshore cable corridor	124 miles (200 kilometers)		X		X	X		X	X	X		X	X				X	X		
Export cable corridor width	2,300 feet (700 meters)		X		X	X		X	X	X		X	X				X	X		
Number of cable/pipeline crossings (COP Volume 1 Table 3-15)	Up to 16				X													X		
Typical separation distance of export cable	164 feet (50 meters)		X		X	X						X	X				X	X		
Seabed preparation (per cable bundle) (boulder field clearance 10 percent of route; grapnel run over the entire route)	65 acres (26 hectares)		X		X	X		X	X	X		X	X	X		X	X			
Cable installation (per cable bundle) (assumes surface impact of 19.7 feet [6 meters] around each cable)	242 acres (98 hectares)		X		X	X		X	X	X		X	X	X		X	X			

Design Parameter	Maximum Design Parameters	3.4.1 Air Quality	3.4.2 Water Quality	3.5.1 Bats	3.5.2 Benthic Resources	3.5.3 Birds	3.5.4 Coastal Habitat and Fauna	3.5.5 Finfish, Invertebrates, and Essential Fish Habitat	3.5.6 Marine Mammals	3.5.7 Sea Turtles	3.5.8 Wetlands and Other Waters of the United States	3.6.1 Commercial Fisheries and For-Hire Recreational Fishing	3.6.2 Cultural Resources	3.6.3 Demographics, Employment, and Economics	3.6.4 Environmental Justice	3.6.5 Land Use and Coastal Infrastructure	3.6.6 Navigation and Vessel Traffic	3.6.7 Other Uses (Marine Minerals, Military Use, Aviation, Scientific Research, and Surveys)	3.6.8 Recreation and Tourism	3.6.9 Visual Resources
Cable protection (per cable bundle) (an estimated 15 percent of the route will require additional cable protection. It is assumed that a 19.7-foot (6-meter)-wide rock berm will be constructed	56 acres (23 hectares)		X		X	X		X	X	X		X	X	X		X	X			
Seabed disturbance area (per cable bundle)	363 acres (147 hectares)		X		X	X		X	X	X		X	X	X		X	X		X	
Total seabed disturbance area (2 cables bundles)	727 acres (294 hectares)		X		X	X		X	X	X		X	X	X		X	X		X	
Onshore Components Falmouth (COP Volume 1 Table 3-18; Table 3-19; Table 3-34; Table 3-39) [b]																				
Landfall locations	Worcester Avenue; Shore Street; or Central Park		X	X		X	X				X		X	X	X	X			X	X

Number of converter stations (HVDC)	Up to 2		X	X		X	X				X		X			X				
Converter station (HVDC) (temporary and permanent impacts)	10 acres each (4.0 hectares)		X	X		X	X				X		X			X				
Alternate Brayton Point underground transmission line	0.2 acre (0.10 hectare)		X	X		X	X				X		X			X				

[a] Footprint includes combined area of foundation, scour protection, and mud mats
[b] To be developed only if Falmouth is the selected point of interconnection for Project 2.

Appendix D: Planned Activities Scenario

Contents

List of Tables

This page intentionally left blank.

D.1 Ongoing and Planned Activities Scenario

This appendix describes the other ongoing and planned activities that could occur in the geographic analysis area for each resource and contribute to baseline conditions and trends for resources considered in this Environmental Impact Statement (EIS). The SouthCoast Wind Project (Project) is the construction, operations and maintenance (O&M), and conceptual decommissioning of a wind energy facility proposed by SouthCoast Wind Energy LLC (SouthCoast Wind) in its Construction and Operations Plan (COP) within the Bureau of Ocean Energy Management (BOEM) Renewable Energy Lease Area OCS-A 0521, approximately 26 nautical miles (nm) (48 kilometers [km]) south of Martha's Vineyard and 20 nm (37 km) south of Nantucket, Massachusetts.

The geographic analysis area varies for each resource as described in the individual resource sections of Chapter 3, *Affected Environment and Environmental Consequences*. BOEM anticipates that impacts could occur from the start of Project construction in 2024 through Project decommissioning. Construction of the Project is anticipated to be completed in approximately 3 years, and the decommissioning phase of the Project is anticipated to be around 35 years after construction is completed.[1] The geographic analysis area is defined by the anticipated geographic extent of impacts for each resource. For the mobile resources—bats, birds, finfish, and invertebrates; marine mammals; and sea turtles—the species potentially affected are those that occur in the area of impact of the Proposed Action. The geographic analysis area for these mobile resources is the general range of the species. The purpose is to capture the cumulative impacts on each of those resources that would be affected by the Proposed Action, as well as the impacts that would still occur under the No Action Alternative.

In this appendix, distances in miles are in statute miles (miles used in the traditional sense) or nm (miles used specifically for marine navigation). This appendix uses statute miles more commonly and refers to them simply as *miles*, whereas nm are referred to by name.

D.2 Ongoing and Planned Activities

This section includes a list and description of ongoing and planned activities that could contribute to baseline conditions and trends in the geographic analysis area for each resource topic analyzed in this EIS. Projects or actions that are considered speculative per the definition provided in 43 Code of Federal

---

[1] SouthCoast Wind's lease with BOEM (Lease OCS-A 0521) has an operations term of 33 years that commences on the date of COP approval (https://www.boem.gov/sites/default/files/renewable-energy-program/State-Activities/MA/Lease-OCS-A-0521.pdf; see also 30 CFR 585.235(a)(3)). SouthCoast Wind would need to request and be granted an extension of its operations term from BOEM to operate the proposed Project for 35 years. While SouthCoast Wind has not made such a request, this EIS uses the longer period to avoid possibly underestimating any potential effects.

Regulations (CFR) 46.30[2] are noted in subsequent tables but excluded from the cumulative impact analysis in Chapter 3.

Ongoing and planned activities described in this section consist of 11 types of actions: (1) offshore wind energy development activities; (2) undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); (3) tidal energy projects; (4) dredging and port improvement projects; (5) marine minerals use and ocean-dredged material disposal; (6) military use; (7) marine transportation; (8) fisheries use, management, and monitoring surveys; (9) global climate change; (10) oil and gas activities; and (11) onshore development activities.

BOEM analyzed the possible extent of future other offshore wind energy development activities on the Atlantic Outer Continental Shelf (OCS) to determine reasonably foreseeable cumulative effects measured by installed power capacity. Attachment 2, Table D2-1, represents the status of projects as of October 1, 2022. The methodology for developing the scenario is the same as for the Vineyard Wind 1 project and details of the scenario development are described in the Vineyard Wind 1 Final EIS (BOEM 2021a).

D.2.1 Offshore Wind Energy Development Activities

D.2.1.1 Site Characterization Studies

A lessee is required to provide the results of site characterization activities with its site assessment plan (SAP) and COP. For the purposes of the cumulative impact analysis, BOEM makes the following assumptions, which represent the maximum-case scenario for survey and sampling activities:

- Site characterization would occur on all existing leases and potential export cable routes.
- Site characterization would likely take place in the first 3 years following execution of a lease, based on the fact that a lessee would likely want to generate data for its COP at the earliest possible opportunity.
- Lessees would likely survey most or all of the proposed Lease Area during the 5-year site assessment term to collect required geophysical information for siting of a meteorological tower, two buoys, and commercial facilities (wind turbines). The surveys may be completed in phases, with the meteorological tower and buoy areas likely to be surveyed first.
- Lessees would not use air guns, which are typically used for deep-penetration two-dimensional or three-dimensional exploratory seismic surveys to determine the location, extent, and properties of oil and gas resources (BOEM 2016).

---

[2] 43 CFR 46.30 – Reasonably foreseeable future actions include those federal and non-federal activities not yet undertaken, but sufficiently likely to occur, that a responsible official of ordinary prudence would take such activities into account in reaching a decision. The federal and non-federal activities that BOEM must take into account in the analysis of cumulative impacts include, but are not limited to, activities for which there are existing decisions, funding, or proposals identified by BOEM. Reasonably foreseeable future actions do not include those actions that are highly speculative or indefinite.

Table D-1 describes the typical site characterization surveys, the types of equipment and method used, and which resources the survey information would inform.

Table D-1. Site characterization survey assumptions

Survey Type	Survey Equipment and Method	Resource Surveyed or Information Used to Inform
HRG surveys	Side-scan sonar, sub-bottom profiler, magnetometer, multi- beam echosounder	Shallow hazards, archaeological, bathymetric charting, benthic habitat
Geotechnical/sub-bottom sampling	Vibracores, deep borings, cone penetration tests	Geological, marine archaeology
Biological	Grab sampling, benthic sled, underwater imagery/sediment profile imaging	Benthic habitat
	Aerial digital imaging; visual observation from boat or airplane	Birds, marine mammals, sea turtles
	Ultrasonic detectors installed on survey vessels used for other surveys	Bat
	Visual observation from boat or airplane	Marine fauna (marine mammals and sea turtles)
	Direct sampling of fish and invertebrates	Fish and invertebrates

Source: BOEM 2016.
HRG = high-resolution geophysical

D.2.1.2 Site Assessment Activities

After SAP approval, a lessee can evaluate the meteorological conditions, such as wind resources, with the approved installation of meteorological towers and buoys. Meteorological buoys have become the preferred meteorological and oceanographic (metocean) data collection platform for developers, and BOEM expects that most future site assessments would use buoys instead of towers (BOEM 2021b). For newly issued plans, BOEM is no longer considering the installation of met towers. The installation and operation of meteorological buoys involves substantially less activity and a much smaller footprint than the construction and operation of a meteorological tower. Site assessment activities have been approved or are in the process of being approved for multiple lease areas consisting of one to three meteorological buoys per SAP (Attachment 2, Table D2-1). Site assessment activities would likely take place starting within 1 to 2 years of lease execution, because preparation of an SAP (and subsequent BOEM review) takes time. The No Action Alternative and cumulative analyses consider these site assessment activities.

D.2.1.3 Construction and Operation of Offshore Wind Facilities

Attachment 2, Table D2-1 lists all offshore wind development activities that BOEM considers reasonably foreseeable by lease areas and projects.

D.2.2 Commercial Fisheries Cumulative Fishery Effects Analysis

Table D-2 depicts future construction of offshore wind projects from Maine to North Carolina including development of Lease Areas OCS-A 0520 and OCS-A 0522 that are proposed offshore Massachusetts adjacent to SouthCoast Wind. Also included are all of the projects currently in various stages of planning within BOEM's offshore leases from Massachusetts to North Carolina. Projected construction dates for each offshore wind project are listed in Attachment 2, Table D2-1, and each project will require a National Environmental Policy Act (NEPA) process with an EIS or environmental assessment prior to approval.

Table D-2 summarizes (1) the incremental number of construction locations that are projected to be active in each region during each year between 2021 and 2030; (2) the number of operational foundations in each region at the beginning of each year between 2021 and 2030; and (3) the total number of active construction locations and operational foundations across the Atlantic OCS by year.

Note that the Kitty Hawk project is included despite its location in the National Oceanic and Atmospheric Administration (NOAA) National Marine Fisheries Service (NMFS) South Atlantic Region. Fishing vessels operating in fisheries managed by the NMFS Greater Atlantic Regional Office regularly harvest in this area. It is also likely that vessels participating in fisheries managed by the NMFS Southeast Regional Office would be affected by the Kitty Hawk project.

BOEM assumes proposed offshore wind projects would include the same or similar components as the proposed Project: wind turbines, offshore and onshore cable systems, offshore substation platform (OSP), onshore O&M facilities, and onshore interconnection facilities. BOEM further assumes that other potential offshore wind projects would employ the same or similar construction, O&M, and conceptual decommissioning activities as the proposed Project. However, offshore wind projects would be subject to evolving economic, environmental, and regulatory conditions. Lease areas may be split into multiple projects, expanded, or removed, and development in a particular lease area may occur in phases over long periods of time. Research currently being conducted in combination with data gathered regarding physical, biological, socioeconomic, and cultural resources during development of initial offshore wind projects in the United States could affect the design and implementation of future projects, as could advancements in technology. For the analysis of ongoing and planned activities the proposed projects included in Attachment 2, Table D2-1 are analyzed in Chapter 3 of this EIS. For a list of mitigation measures that were considered in the impact analysis in Chapter 3 of this EIS, please see Appendix G, *Mitigation and Monitoring*.

[a] BOEM recognizes that the estimates presented within this cumulative analysis are likely high, conservative estimates; however, BOEM believes that this analysis appropriately captures the potential cumulative impacts and errs on the side of maximum impacts.
[b] New England Wind Phase I and Phase 2 would collectively have no more than 130 foundations, and the maximum number of foundations for Phase I would be 64.
[c] Beacon Wind 1 and Beacon Wind 2 would collectively have no more than 157 foundations. BOEM made the assumption to split the foundation numbers evenly across both projects.
CVOW = Coastal Virginia Offshore Wind; GSOE = Garden State Offshore Energy

D.2.3 Incorporation by Reference of Cumulative Impacts Study and the Analyses Therein

BOEM has completed a study of impact-producing factors (IPFs) on the North Atlantic OCS to consider in an offshore wind development cumulative impacts scenario (BOEM 2019). The study is incorporated in this document by reference. The study identifies cause-and-effect relationships between renewable energy projects and resources potentially affected by such projects. It further classifies those relationships into a manageable number of IPFs through which renewable energy projects could affect resources. It also identifies the types of actions and activities to be considered in a cumulative impact scenario. The study identifies actions and activities that may affect the same physical, biological, economic, or cultural resources as renewable energy projects, and observes that such actions and activities may have the same IPFs as offshore wind projects.

The BOEM (2019) study identifies the relationships between IPFs associated with specific ongoing and planned activities in the North Atlantic OCS to consider in a NEPA cumulative impacts scenario. These IPFs and their relationships were used in the EIS analysis of cumulative impacts.

As discussed in the BOEM (2019) study, reasonably foreseeable activities other than offshore wind projects may also affect the same resources as the proposed Project or other offshore wind projects, possibly via the same IPFs or via IPFs through which offshore wind projects do not contribute. This appendix lists reasonably foreseeable non-offshore wind activities that may contribute to the cumulative impacts of the proposed Project.

D.2.4 Undersea Transmission Lines, Gas Pipelines, and Other Submarine Cables

Several in-service and abandoned submarine telecommunications cables are present in the offshore export cable corridor and in the vicinity of the Lease Area (COP Volume 2, Figure 14-6, Table 14-2; SouthCoast Wind 2024). The Brayton Point export cable corridor could have up to 13 crossings of planned cables and up to 3 crossings of existing pipelines. The Falmouth export cable corridor could have up to 2 crossings of existing cables and more than 7 crossings of planned cables associated with the Vineyard Wind and New England Wind 1 projects and New England Wind offshore wind projects.

The offshore wind projects listed in Attachment 2, Table D2-1 that have a COP under review are presumed to include at least one identified cable route. Cable routes have not yet been announced for the remainder of the projects.

D.2.5 Tidal Energy Projects

The Bourne Tidal Test Site located in the Cape Cod Canal near Bourne, Massachusetts, is a testing platform for tidal turbines that was installed in late 2017 by the Marine Renewable Energy Collaborative. The Bourne Tidal Test Site offers a test platform for tidal turbines (MRECo 2017, 2018). On behalf of the Marine Renewable Energy Collaborative of New England, Barrett Energy Resources Group, LLC (BERG) filed a Draft Pilot License Application dated November 3, 2021. The Draft Pilot License Application is an application to interconnect and operate a marine hydrokinetic test facility (the Bourne Tidal Test Site) (Barrett 2021).

The Roosevelt Island Tidal Energy Project is in the East Channel of the East River, a tidal strait connecting Long Island Sound with the Atlantic Ocean in New York Harbor. In 2005, Verdant Power petitioned the Federal Energy Regulatory Commission (FERC) for permission for the first U.S. commercial license for tidal power. In 2012, FERC issued a 10-year license to install up to 1 megawatt (MW) of power (30 turbines/10 TriFrames) at the Roosevelt Island Tidal Energy Project (FERC 2012a; Verdant Power 2022).

The Cobscook Bay Tidal Project, located in Maine, is a FERC-licensed tidal project that began operations in 2012 (FERC 2012b). The project owner, Ocean Renewable Power Company, informed FERC in a March 14, 2017, submittal that it did not intend to file a notice of intent (NOI) to relicense the project or a Pre-Application Document at the time. The Ocean Renewable Power Company anticipates that the project infrastructure, environmental monitoring and data analysis efforts, resource information documentation, and collaborative relationships with existing marine users will continue through the duration of the existing pilot license term through 2022 and potentially beyond (PNNL 2020). The Western Passage Tidal Energy Project, a proposed tidal energy site in the Western Passage, received a preliminary permit from FERC in 2016. The preliminary permit allows developers to study a project but does not authorize construction (PNNL 2021).

D.2.6 Dredging and Port Improvement Projects

The following dredging and port improvement projects have been proposed or studied at ports that may be used by the Project in Massachusetts, Rhode Island, Connecticut, South Carolina, Texas, and Maryland, and are either funded/under construction projects or are considered reasonably foreseeable.

- **Point Judith, Port of Galilee, Rhode Island.** The Rhode Island Department of Environmental Management (RIDEM), which operates the Port of Galilee, a Narragansett-based commercial fishing port, began four projects in 2022 in the north bulkhead area of the port totaling nearly $15 million in investments. At the end of 2023, RIDEM was in the third phase of a multi-year investment with work aimed at the replacement of bulkheads and docks, water supply, electrical, and security upgrades, and improvements to bolster the port against the effects of climate change (Office of the Governor of Rhode Island 2022; State of Rhode Island Department of Environmental Management 2023).
- **Port of Davisville, Rhode Island.** The Rhode Island Fiscal Year 2023 budget included $60 million and $35 million, respectively, for infrastructure upgrades to the Port of Davisville and the South Quay Marine Terminal in East Providence to support offshore wind activities on the U.S. East Coast. The funding for the Port of Davisville would support construction of the port’s Terminal 5 Pier and completion of required dredging, preparation of about 34 acres to accommodate additional cargo laydown, and reconstruction and hardening of the existing surface of Pier 1 (Buljan 2022).
- **Massachusetts Port Authority.** The Port of Massachusetts is implementing an $850 million port upgrade project to accommodate larger freight vessels. Project work includes dredging of Boston Harbor, construction of a new berth, and installation of new ship-to-shore cranes (Glenn 2021).

- **Port of New Bedford, Massachusetts.** The New Bedford Port Authority recently completed a $17 million project to expand the North Terminal at the Port of New Bedford; adding 150,000 square feet of terminal space. The bulkhead was constructed using up to 97,000 yards of contaminated dredge material (Port of New Bedford 2022; Standard Times 2022). Additionally, the New Bedford Port Authority has been awarded $24 million to reconstruct and extend Leonard's Wharf to support commercial fishing and the offshore wind industry (Standard Times 2023).
- **New London Heavy Lift Port, Connecticut.** The Connecticut Port Authority is conducting a project to redevelop the Port of New London State Pier as a heavy-lift capable port facility, in partnership with terminal operator Gateway Terminal, and joint venture partners Ørsted and Eversource. Heavy-lift capability would support various cargoes including wind turbine construction staging and pre-assembly, including construction support for the South Fork, Revolution Wind, and Sunrise offshore wind projects. Environmental permits for in-water work and onshore construction were issued in December 2021(Connecticut Port Authority 2021a; 2021b; CT Examiner 2022). Operations began at the port in 2023 though a portion of the site remains under construction (CT Insider 2023).
- **Sparrows Point Port, Maryland.** The Sparrows Point Container Terminal project will construct a new container terminal and intermodal yard located on 330 acres within the Tradepoint Atlantic industrial development site on Sparrows Point. In addition to onshore development, the project would include the widening and deepening of an existing channel and connection into the Brewerton Federal Navigation channel. USACE is currently preparing an EIS for the project (88 FR 87414).
- **Port of Charleston, South Carolina.** Construction is currently underway at the Port of Charleston on a near-dock rail-served cargo yard and inner-harbor barge operation. The $400 million Navy Base Intermodal Facility and $150 million inner-harbor barge operation includes the construction of almost 80,000 feet of rail track and will establish a designated marine highway to move shipping containers. Construction on the project is anticipated to be complete by July 2025 (South Carolina Ports Authority 2022).
- **Port of Corpus Christi, Texas.** The $681.6 million Channel Improvement Project to widen the channel to 530 feet and deepen to 54 feet is in the final construction phase and is estimated to be complete in early 2025 (Port of Corpus Christi 2023).

D.2.7 Marine Minerals Use and Ocean Dredged Material Disposal

To help meet the sand resource needs of coastal communities, BOEM-funded reconnaissance or design-level OCS studies along the East Coast from Rhode Island to Florida have identified potential future sand resources in many areas. Sand resources identified nearest the Project include OCS locations offshore Massachusetts and Rhode Island; many of these potential sand resources are within 5 miles of the Project Lease Area and associated planned infrastructure (e.g., export cables) (Mabee and Woodruff 2016; King et al. 2016). Topographic profiles and grain size analyses were performed on sediment samples collected at 18 Massachusetts beaches experiencing erosion were taken during the summer and winter seasons from 2014 through 2016 to evaluate seasonal and spatial variability. This information will be used primarily to match native-beach material with compatible offshore sand resources for beach nourishment projects (BOEM 2016).

U.S. Environmental Protection Agency (USEPA) Region 1 is responsible for designating and managing ocean disposal sites for all materials except dredged material in the region of the Project. Under Section 103 of the Marine Protection, Research and Sanctuaries Act (MPRSA) (33 USC 1401 et seq.), USACE regulates the transportation of dredged material for purposes of dumping it into ocean water. There is one USEPA-designated open-ocean disposal site along the southern Massachusetts/Rhode Island Coast, the Rhode Island Sound Disposal Site located approximately 10 miles northeast of Block Island. The Rhode Island Sound Disposal Site was first used in 2003 and was last used in 2019 (USACE 2022). The Eastern Long Island Sound Disposal Site offshore New London, Connecticut is designated for offshore disposal and is in use (USACE 2022).

D.2.8 Military Use

The Lease Area is within the Narragansett Bay Operations Area. The Narragansett Bay Operations Area extends from the shoreline seaward to approximately 180 nm from land at its farthest point; the subsurface portion of the Narragansett Bay Operations Area has the same boundaries as the surface water portion. The offshore Narragansett Bay Range Complex provides infrastructure for U.S. Atlantic Fleet training and testing exercises (U.S. Navy 2018). The offshore Narragansett Bay Range Complex also supports training and testing by other services (Ecology & Environment 2016).

Military activities with the Narragansett Bay Range Complex can include various vessel training exercises, submarine and antisubmarine training, and U.S. Air Force exercises. The U.S. Navy, the U.S. Coast Guard (USCG), and other military entities have numerous facilities in the region. Major onshore regional facilities include Joint Base Cape Cod, Naval Station Newport, Newport Naval Undersea Warfare Center, Naval Submarine Base New London, and USCG Academy (BOEM 2013; Rhode Island Coastal Resources Management Council 2010). The U.S. Atlantic Fleet also conducts training and testing exercises in the Narraganset Bay Operations Area, and the Newport Naval Undersea Warfare Center routinely performs testing in the area (BOEM 2013).

D.2.9 Marine Transportation

Marine transportation in the region is diverse and sourced from many ports and private harbors. Commercial vessel traffic in the region includes research, tug/barge, tankers (such as those used for liquid petroleum), cargo, cruise ships, smaller passenger vessels, and commercial fishing vessels. Recreational vessel traffic includes private motorboats and sailboats. A number of federal agencies, state agencies, educational institutions, and environmental non-governmental organizations participate in ongoing research offshore including oceanographic, biological, geophysical, and archaeological surveys. The Northeast Regional Planning Body anticipates that major vessel traffic routes will be relatively stable in the region for the foreseeable future, but that coastal developments and market demands that are unknown at this time could affect them (Northeast Regional Planning Body 2016). Most vessel traffic, excluding recreational vessels, tends to travel within established vessel traffic routes and the number of trips, as well as the number of unique vessels, has remained consistent (USCG 2021). In response to future offshore wind projects in the New York Bight, multiple additional fairways and a new anchorage may be established to route existing vessel traffic around wind energy projects (USCG

2021). Two Maritime Highway Routes are designated in the Atlantic Coast by the U.S. Department of Transportation Maritime Administration; Marine Highway M-95 (Atlantic Ocean Coastal Waters) that extends from Florida to Maine and Marine Highway M-295 that includes the East River (New York Harbor), Long Island Sound (New York and Connecticut) to Block Island Sound (Rhode Island) (USDOT 2022).

D.2.10 National Marine Fisheries Service Activities

Research and enhancement permits may be issued for marine mammals protected by the Marine Mammal Protection Act (MMPA) and for threatened and endangered species protected under the federal Endangered Species Act (ESA). NMFS is anticipated to continue issuing research permits under Section 10(a)(1)(A) of the ESA to allow take of certain ESA-listed species for scientific research. Scientific research permits issued by NMFS currently authorize studies on ESA-listed species in the Atlantic Ocean. Current fisheries management and ecosystem monitoring surveys conducted by or in coordination with the Northeast Fisheries Science Center (NEFSC) could overlap with offshore wind lease areas in the New England region and south into the Mid-Atlantic region. Surveys include (1) the NEFSC Bottom Trawl Survey, a more than 50-year multispecies stock assessment tool using a bottom trawl; (2) the NEFSC Sea Scallop/Integrated Habitat Survey, a sea scallop stock assessment and habitat characterization tool, using a bottom dredge and camera tow; (3) the NEFSC Surfclam/Ocean Quahog Survey, a stock assessment tool for both species using a bottom dredge; and (4) the NEFSC Ecosystem Monitoring Program, a more than 40-year shelf ecosystem monitoring program using plankton tows and conductivity, temperature, and depth units. These surveys are anticipated to continue within the region, regardless of offshore wind development.

The regulatory process administered by NMFS, which includes stock assessments for all marine mammals and 5-year reviews for all ESA-listed species, assists in informing decisions on take authorizations and the assessment of project-specific and cumulative impacts that consider ongoing and planned activities in biological opinions. Stock assessments completed regularly under the MMPA include estimates of potential biological removal that stocks of marine mammals can sustainably absorb. MMPA take authorizations require that a proposed action have no more than a negligible impact on species or stocks, and that a proposed action impose the least practicable adverse impact on the species. MMPA authorizations are reinforced by monitoring and reporting requirements so that NMFS is kept informed of deviations from what has been approved. Biological opinions for federal and non-federal actions are similarly grounded in status reviews and conditioned to avoid jeopardy and to allow continued progress toward recovery. These processes help to ensure that, through compliance with these regulatory requirements, a proposed action would not have a measurable impact on the conservation, recovery, and management of the resource.

D.2.10.1 Directed Take Permits for Scientific Research and Enhancement

NMFS issues permits for scientific research on protected species. These research permits include the authorization of directed take for activities, such as capturing animals and taking measurements and biological samples to study their health, tagging animals to study their distribution and migration, photographing and counting animals to get population estimates, taking animals in poor health to an animal hospital, and filming animals. NMFS also issues permits for enhancement purposes; these permits are issued to enhance the survival or recovery of a species or stock in the wild by taking actions that increase an individual's or population's ability to recover in the wild. Scientific research and enhancement permits have been issued previously for satellite, acoustic, and multi-sensor tagging studies on large and small cetaceans; research on reproduction, mortality, health, and conservation issues for NARWs; and research on population dynamics of harbor and gray seals. Reasonably foreseeable future impacts from scientific research and enhancement permits include physical and behavioral stressors (e.g., restraint and capture, marking, implantable and suction tagging, biological sampling).

D.2.10.2 Fisheries Use and Management

NMFS implements regulations to manage commercial and recreational fisheries in federal waters, including those within which the Project would be located; the State of Massachusetts regulates commercial fisheries in state waters (within 3 nm of the coastline). There are no aquaculture leases in the vicinity of the Falmouth landfall locations (SouthCoast Wind 2024). There are nine approved aquaculture leases located near the Brayton Point offshore export cable in and near the Sakonnet River that are mostly for oysters but also for clams, scallops, and quahogs (RIDEM 2022). The Project (including landfall and potential marshalling and O&M port locations) overlaps four of NMFS's eight regional councils to manage federal fisheries: Mid-Atlantic Fishery Management Council (MAFMC), which includes New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia, and North Carolina; South Atlantic Fishery Management Council, which includes North Carolina, South Carolina, Georgia, and part of Florida; the Gulf of Mexico Fishery Management Council, which includes part of Florida, Louisiana, Alabama, Mississippi, and Texas; and New England Fishery Management Council (NEFMC), which includes Maine, New Hampshire, Massachusetts, Rhode Island, and Connecticut (NEFMC 2022). The councils manage species with many Fishery Management Plans (FMPs) that are frequently updated, revised, and amended and coordinate with each other to jointly manage species across jurisdictional boundaries (MAFMC 2022). Many of the fisheries managed by the councils are fished for in state waters or outside of the Mid-Atlantic region, so the council works with the Atlantic States Marine Fisheries Commission (ASMFC). The ASMFC is composed of the 15 Atlantic coast states and coordinates the management of marine and anadromous resources found in the states' marine waters. In addition, the states and NMFS, under the framework of ASMFC's *Amendment 3 to the Interstate Fishery Management Plan for American Lobster*, cooperatively manage the American lobster resource and fishery (NOAA 1997).

The FMPs of the councils and ASMFC were established, in part, to manage fisheries to avoid overfishing. They accomplish this through an array of management measures, including annual catch quotas, minimum size limits, and closed areas. These various measures can further reduce (or increase) the size of landings of commercial fisheries in the Northeast and Mid-Atlantic regions.

NMFS also manages highly migratory species, such as tuna and sharks, that can travel long distances and cross domestic boundaries. Table D-3 summarizes other FMPs and actions in the region.

Table D-3. Other fishery management plans

Area	Plan and Projects
ASMFC	ASMFC Five-Year Strategic Plan 2019–2023 (ASMFC 2019) ASMFC 2022 Action Plan (ASMFC 2021) Management, Policy and Science Strategies for Adapting Fisheries Management to Changes in Species Abundance and Distribution Resulting from Climate Change (ASMFC 2018).
Massachusetts	Massachusetts Shellfish Initiative 2021–2025 Strategic Plan (MSI 2021).
Rhode Island	Rhode Island 2018 Shellfish Sector Management Plan (RIDEM 2018) Rhode Island Department of Environmental Management Division of Marine Fisheries Strategic Plan (2021–2025) (RIDEM 2021).
Connecticut	Town of Groton, Connecticut Shellfish Management Plan (Town of Groton 2020).
Maryland	The Maryland Department of Natural Resources implements fishery management plans for the following species: American eel, Atlantic croaker, black drum, black sea bass, blue crab within the Chesapeake Bay, blue crab within coastal bays, bluefish, brook trout, catfish, eastern oyster, hard clam within coastal bays, horseshoe crab, largemouth bass, Spanish and king mackerel, red drum, alewife and blueback river herring, American and hickory shad, spot, spotted seatrout, striped bass, summer flounder, tautog, weakfish, and yellow perch (Maryland DNR 2024).
South Carolina	S.C. Sea Grant Consortium Strategic Plan, 2024–2027 (S.C. Sea Grant Consortium 2024).
Texas	The Texas Parks and Wildlife Department implements fisheries management programs including operation of hatcheries and development of artificial reefs and habitat projects (TPWD 2024).

D.2.11 Global Climate Change

Climate change results primarily from the increasing concentration of greenhouse gas (GHG) emissions in the atmosphere, which causes planet-wide physical, chemical, and biological changes, substantially affecting the world's oceans and lands. Changes include increases in global atmospheric and oceanic temperature, shifting weather patterns, rising sea levels, and changes in atmospheric and oceanic chemistry (Blunden and Arndt 2020). Section 7.6.1.4 of the *Programmatic EIS for Alternative Energy Development and Production and Alternate Use of Activities on the Outer Continental Shelf* (MMS 2007) describes global climate change with respect to assessing renewable energy development. Key drivers of climate change are increasing atmospheric concentrations of carbon dioxide (CO_2) and other GHGs, such as methane (CH_4) and nitrous oxide (N_2O). These GHGs reduce the ability of solar radiation to reradiate out of Earth's atmosphere and into space. Although all three of these GHGs have natural sources, the majority of these GHGs are released from anthropogenic activity. Since the industrial revolution, the rate at which solar radiation is reradiated back into space has slowed due to increasing GHG concentrations in the atmosphere, resulting in a net increase of energy in the Earth's system (Solomon et al. 2007). This energy increase presents as heat, raising the planet's temperature and causing climate change.

Fluorinated gases are a type of GHG released in trace amounts but are highly efficient at preventing solar radiation from being re-radiated back into space. They have a much longer lifespan than CO_2, CH_4, and N_2O. Fluorinated gases have no natural sources, are either a product or byproduct of manufacturing, and can have 23,000 times the warming potential of an equal amount of CO_2. These gases include hydrofluorocarbons, perfluorocarbons, nitrogen trifluoride, and sulfur hexafluoride. These gases are currently being phased out; however, sulfur hexafluoride is still used in wind turbine generator (WTG) switchgears and OSP high-voltage and medium-voltage gas-insulated switchgears.

The Intergovernmental Panel on Climate Change released a special report in October 2018 that compared risks associated with an increase of global warming of 1.5 degrees Celsius (°C) and an increase of 2°C. The report found that climate-related risks depend on the rate, peak, and duration of global warming, and that an increase of 2°C was associated with greater risks associated with climatic changes such as extreme weather and drought; global sea level rise; impacts on terrestrial ecosystems; impacts on marine biodiversity, fisheries, and ecosystems and their functions and services to humans; and impacts on health, livelihoods, food security, water supply, and economic growth (IPCC 2018). Higher global temperatures increase the chances of sea level rise by the end of the century, with a projected relative seal level rise of 0.6 to 2.2 meters along the contiguous U.S. coastline by 2100 (NOAA 2022). Expected relative sea level rise would cause tide and storm surge heights to increase, leading to a shift in the U.S. coastal flood regimes by 2050 with major and moderate high tide flood events occurring as frequently as moderate and minor high tide flood events occur today (NOAA 2022).

Global emissions of GHGs have impacts whose local effects are increasingly elucidated through research. For example, a recent study concerning North Atlantic right whale provides evidence that the whale's feeding area moved north following relocation of its food source related to climate change, and whale mortality may have increased because of fewer controls on fishing activities in the new, more northerly area (Meyer-Gutbrod et al. 2021). Climate change is predicted to affect Northeast fishery species in different ways (Hare et al. 2016), and the NMFS biological opinion discusses in detail the potential impacts of global climate change on protected species that occur within the Proposed Action area (NMFS 2013).

Local emissions, such as those from maintenance of and accidental chemical leaks from wind energy projects, would contribute incrementally to global GHG emissions. However, the largest climate impact from wind energy projects is expected to be beneficial: the energy generated by wind energy projects is expected to displace energy generated by combustion of fossil fuels, which would lead to reductions in regional emissions of air pollutants and GHGs from fossil-fueled power plants.

Table D-4 summarizes regional plans and policies that are in place to address climate change, and

Table D-5 summarizes resiliency plans.

Table D-4. Climate change plans and policies

Plans and Policies	Summary/Goal
Massachusetts	
Global Warming Solutions Act of 2008	Framework to reduce GHG emissions by requiring 25% reduction in emissions from all sectors below 1990 baseline emissions level in 2020, at least 80% reduction in 2050. Full implementation of these policies is projected to result in total net reduction of 25.0 million metric tons of carbon dioxide equivalent, or 26.4% below 1990 baseline level (Commonwealth of Massachusetts 2018a).
Massachusetts Clean Energy and Climate Plan for 2025 and 2030	Interim policy that updates the 2015 and 2020 climate plans. Policies that aim to reduce GHG emissions in the commonwealth across all sectors; full implementation of policies would result in reducing emissions by at least 50% below 1900 level in 2030 (Commonwealth of Massachusetts 2020a).
An Act Creating a Next-Generation Roadmap for Massachusetts Climate Policy (2021)	Requires the Secretary of the Executive Office of Energy and Environmental Affairs to set interim emissions limit and sector-specific sublimit every 5 years. Calls for the 2030 emissions limit to be at least 50% below the 1990 baseline, the 2040 emissions limit to be at least 75% below the 1990 baseline, and a 2050 emissions limit that achieves at least net zero statewide GHG emissions, provided that in no event shall the emissions in 2050 be higher than a level 85% below the 1990 baseline (Commonwealth of Massachusetts 2021).
Massachusetts 2050 Decarbonization Roadmap (2020)	Framework for long-term and short-term strategies to reach net zero statewide greenhouse gas emissions by 2050 (Commonwealth of Massachusetts 2020b).
Executive Order 569, Establishing an Integrated Climate Strategy for the Commonwealth and "Act to Promote Energy Diversity" (2016)	Calls for large procurements of offshore wind and hydroelectric resources (Commonwealth of Massachusetts 2016).
Environmental Bond Bill and An Act to Advance Clean Energy (2018)	Sets new targets for offshore wind, solar, and storage technologies; expands Renewable Portfolio Standard requirements for 2020–2029; establishes a Clean Peak Standard; and permits fuel switching in energy efficiency programs.
Massachusetts State Hazard Mitigation and Climate Adaptation Plan 2018	Updated 2013 plan to comprehensively integrate climate change impacts and adaptation strategies with hazard mitigation planning while complying with federal requirements for state hazard mitigation plans and maintaining eligibility for federal disaster recovery and hazard mitigation funding under the Stafford Act. The plan received FEMA-approval and is effective through September 2023 (Commonwealth of Massachusetts 2018b).
Rhode Island	
Resilient Rhode Island Act (2014)	The 2014 Resilient Rhode Island Act established the Executive Climate Change Coordinating Council. It also set specific GHG emissions reduction targets; established an advisory board and a science and technical advisory board to assist the council; and incorporated consideration of climate change impacts into the powers and duties of all state agencies. The Executive Climate Change Coordinating Council is charged with developing and tracking the implementation of a plan to achieve GHG emissions reductions below 1990 levels of 10% by 2020, 45% by 2035, and 80% by 2050 (State of Rhode Island 2014).

Plans and Policies	Summary/Goal
Rhode Island 2021 Act on Climate (Section 42, Chapter 6.2)	The 2021 Act on Climate sets mandatory, enforceable climate emissions reduction goals leading the state to achieve net-zero emissions economy-wide by 2050. This legislation updates the previous 2014 Resilient Rhode Island Act.
Connecticut	
Executive Order 3 (2019)	Executive Order 3 established a framework for monitoring and reporting on the state's implementation of GHG emissions reduction strategies set forth in the previous Governor's Council on Climate Change, and a framework to develop a statewide Adaptation and Resilience Plan for Connecticut (State of Connecticut 2019).
Executive Order 21-3 (2021)	Executive Order 21-2 establishes policies for energy efficiency and resiliency, including conducting a State Vulnerability Assessment of state government assets and operations and climate resilience project pipeline (State of Connecticut 2021a).
Maryland	
Climate Solutions Now Act of 2022 (Article II, Section 17(b), Chapter 38).	The Climate Solutions Now Act of 2022 calls for Maryland to reduce GHG by 60% as compared to a 2006 baseline by 2031 and for the Maryland economy to reach net-zero emissions by 2045.
Maryland's Climate Pollution Reduction Plan (2023)	Establishes plans to achieve net-zero emissions by 2045 through incentives for home electrification, electric vehicles, and commercial building efficiency and investments in infrastructure and natural and working lands (Maryland Department of the Environment 2023).
South Carolina	
Charleston, South Carolina Climate Action Plan (2021)	Establishes a five-year framework for the city of Charleston to reduce emissions by 56% by 2030 and to net-zero by 2050 (City of Charleston 2021).
Texas	
Texas Coastal Resiliency Master Plan (2023)	Texas General Land Office 2023 *Texas Coastal Resiliency Master Plan* is the third installment of a statewide plan to protect and promote a vibrant and resilient Texas coast (Texas General Land Office 2023). The Resiliency Master Plan identifies ten actions to coordinate Texas's coastal resiliency needs: • Managing coastal habitats • Managing gulf shorelines • Managing bay shorelines • Improving community resilience • Adapting to changing conditions • Managing watersheds • Growing key knowledge and experience • Enhancing emergency preparation and response • Addressing under-represented needs • Maintaining coastal economic growth

Table D-5. Resiliency plans and policies in the Lease Area

Plans and Policies	Summary
Massachusetts	
Municipal Vulnerability Preparedness grant program (2017)	Created as part of Executive Order 568, the Municipal Vulnerability Preparedness grant program provides support for cities and towns in Massachusetts to identify climate hazards, assess vulnerabilities, and develop action plans to improve resilience to climate change (Climate Change Clearinghouse for the Commonwealth 2022).
Coastal Grant and Resilience Program	Provide financial and technical support for local and regional efforts to increase community understanding of coastal storm and climate impacts, evaluate vulnerabilities, conduct adaptation planning, redesign and retrofit vulnerable public facilities and infrastructure, and restore shorelines to enhance natural resources and provide storm damage protection. The Town of Falmouth was awarded a grant in 2022 for a project to address erosion along the Eel River Inlet shoreline (Commonwealth of Massachusetts 2022).
Rhode Island	
Rhode Island Executive Order 17-10: Action Plan to Stand Up to Climate Change (2017)	Executive Order 17-10 established the office of the Rhode Island Resiliency Officer. The Rhode Island Executive Climate Change Coordinating Council works with the Resiliency Officer to develop climate preparedness strategies.
Rhode Island Shoreline Change Special Area Management Plan (Rhode Island Coastal Resources Management Council 2018)	The Shoreline Change Special Area Management Plan (SAMP) provides information, guidance, and a suite of tools to empower state and local decision makers as they plan for, recover from, and successfully adapt to the impacts of coastal storms, erosion, and sea level rise (Rhode Island Coastal Resources Management Council 2018).
Connecticut	
Public Act No. 21-115 An Act Concerning Climate Change Adaptation (2021)	This act authorizes Connecticut municipalities to establish a municipal stormwater authority, broadens the authority of municipal flood and erosion control boards to include flood prevention and climate resilience and allows municipalities to form joint boards, and establishes an Environmental Infrastructure Fund (State of Connecticut 2021b).
Taking Action on Climate Change and Building a More Resilient Connecticut for All – Phase I Report (Office of the Governor of Connecticut 2021)	The Phase I report implements provisions of Executive Order 3, including a report on the progress on mitigation strategies and recommendations. Continued reporting on implementation of the mitigation strategies was also called for annually in the Executive Order. The framework for inventory of vulnerable assets and operations and the report from state agencies on adaptation strategies in their planning processes required under Executive Order Objective 2 is to be included in the Phase 2 report.
Maryland	
Maryland Senate Bill 457: Resilience Authorities (2020)	This bill authorizes local governments to establish and fund a resilience authority to fund large-scale infrastructure projects aimed as addressing the effects of climate change.

South Carolina	
Disaster Relief and Resilience Act (2020)	Establishes the South Carolina Office of Resilience to coordinate disaster recovery and resilience efforts within South Carolina, creates the Disaster Relief and Resilience Reserve Fund to finance disaster recovery efforts and hazard mitigation projects, and creates the Resilience Revolving Fund to provide low-interest loans to local governments to perform floodplain buyouts and restoration.
Strategic Statewide Resilience and Risk Reduction Plan (2023)	Serves as the framework to guide state investment in flood mitigation projects and the adoption of programs and policies to protect the people and property of South Carolina from the damage and destruction of extreme weather events (South Carolina Office of Resilience 2023).
Texas	
Texas Coastal Resiliency Master Plan (2017)	The Texas Coastal Resiliency Master Plan was developed to direct future management of Texas coastline in support of sustaining resilient communities and coastal ecosystems (Texas General Land Office 2017).
Texas Infrastructure Resiliency Fund (2019)	The Texas Infrastructure Resiliency Fund was established to finance flood mitigation and protection projects and related planning efforts. It includes funds for federal matching to implement projects already eligible for partial federal funding; floodplain management for flood planning, protection, mitigation, or adaption projects; flood plan implementation for projects included in the state flood plan; and the Hurricane Harvey fund to implement projects related to Hurricane Harvey recovery.

D.2.12 Oil and Gas Activities

The proposed Project area is in the North Atlantic Planning Area of the OCS Oil and Gas Leasing Program (National OCS Program). On September 8, 2020, the White House issued a presidential memorandum for the Secretary of the Interior on the withdrawal of certain areas of the United States OCS from leasing disposition for 10 years, including the areas currently designated by BOEM as the South Atlantic and Straits of Florida Planning Areas (White House 2020a). The South Atlantic Planning Area includes the OCS off South Carolina, Georgia, and northern Florida. On September 25, 2020, the White House issued a similar memorandum for the Mid-Atlantic Planning Area that lies south of the northern administrative boundary of North Carolina (White House 2020b). This withdrawal prevents consideration of these areas for any leasing for purposes of oil and gas exploration, development, or production during the 10-year period beginning July 1, 2022 and ending June 30, 2032. However, currently, there has been no decision by the Secretary of the Interior regarding future oil and gas leasing in the North Atlantic or remainder of the Mid-Atlantic Planning Areas. Existing leases in the withdrawn areas are not affected.

BOEM issues geological and geophysical permits to obtain data for hydrocarbon exploration and production; locate and monitor marine mineral resources; aid in locating sites for alternative energy structures and pipelines; identify possible manmade, seafloor, or geological hazards; and locate potential archaeological and benthic resources. Geological and geophysical surveys are typically classified into categories by equipment type and survey technique. There are currently no such permits under review for areas offshore Massachusetts or Rhode Island (BOEM 2022).

Several liquefied natural gas ports are on the East Coast of the United States. Table D-6 lists existing and proposed liquified natural gas ports on the East Coast that provide (or may provide in the future) services such as natural gas export, natural gas supply to the interstate pipeline system or local distribution companies, storage of liquified natural gas for periods of peak demand, or production of liquified natural gas for fuel and industrial use (FERC 2022).

Table D-6. Liquid natural gas terminals in the eastern United States

Terminal Name	Type	Company	Jurisdiction	Distance from Project (approximate)	Status
Everett, MA	Import terminal	GDF SUEZ— DOMAC	FERC	90 miles north	Existing
Offshore Boston, MA	Import terminal	Neptune LNG	MARAD/USCG	100 miles north	Existing
Offshore Boston, MA	Import terminal, authorized to re-export delivered LNG	Excelerate Energy—Northeast Gateway	MARAD/USCG	95 miles north (Buoy B)	Existing
Cove Point, MD (Chesapeake Bay)	Import terminal/ Export Terminal	Dominion—Cove Point LNG	FERC	340 miles southwest	Existing
Elba Island, GA (Savannah River)	Import terminal	El Paso—Southern LNG	FERC	835 miles southwest	Existing
Elba Island, GA (Savannah River)	Import Terminal/ Export terminal	Southern LNG Company	FERC	835 miles southwest	Existing
Jacksonville, FL	Export terminal	Eagle LNG Partners	FERC	960 miles southwest	Proposed

Source: FERC 2022.
DOMAC = Distrigas of Massachusetts Corporation; GDF = Gaz de France; FL = Florida; GA = Georgia; LNG = liquified natural gas; MA = Massachusetts; MARAD = U.S. Department of Transportation Maritime Administration; MD = Maryland.

D.2.13 Onshore Development Activities

Onshore development activities that may contribute to cumulative impacts include visible infrastructure, such as onshore wind turbines and cell towers, port development, and other energy projects, such as transmission and pipeline projects. Coastal development projects permitted through regional planning commissions, counties, and towns may also contribute to cumulative impacts. These may include residential, commercial, and industrial developments spurred by population growth in the region (Table D-7).

Table D-7. Existing, approved, and proposed onshore development activities

Type	Description
Local planning documents	*Massachusetts* Town of Falmouth Local Comprehensive Plan (Town of Falmouth 2016). City of New Bedford City Master Plan (City of New Bedford 2010). Town of Somerset Master Plan (Town of Somerset 2020).
	Rhode Island Town of Bristol 2016 Comprehensive Community Plan (Town of Bristol 2016). Town of Portsmouth Comprehensive Community Plan (Town of Portsmouth 2021). Town of North Kingstown Comprehensive Plan (Town of North Kingstown 2019). Town of Tiverton 2018 Comprehensive Plan (Town of Tiverton 2018). Providence Tomorrow, City of Providence Comprehensive Plan (City of Providence 2014). Aquidneck Island Planning Commission (AIPC 2022).
	Connecticut City of New London Strategic Plan (City of New London 2017).
	Maryland Baltimore County Master Plan 2030 (Baltimore County Department of Planning 2023).
	South Carolina Charleston 2021 City Plan (Charleston Planning Commission 2021).
	Texas Corpus Christi, Plan CC Comprehensive Plan (City of Corpus Christi 2016).
Onshore wind projects	According to the USGS, there are no onshore wind projects within the 42.8-mile (68.9-kilometer) viewshed of the Project (USGS 2022).
Communications towers	There are numerous communications towers in communities within the viewshed of the Project. For example, there are 17 communications towers and 102 antennas within a 3-mile radius of Falmouth, Massachusetts; 55 communications towers and 360 antennas within a 3-mile radius of Brayton Point, Massachusetts; and 96 communications towers and 396 antennas within a 3-mile radius of the Port of New Bedford, Massachusetts (AntennaSearch.com 2022).

Type	Description
Development projects	*Massachusetts* City of New Bedford • The South Coast Rail project aims to restore commuter rail service between Boston and southeastern Massachusetts, including the City of New Bedford. Phase 1 construction is underway and will be complete by the end of 2023 (Massachusetts Bay Transportation Authority 2022). • An Offshore Wind Control Center is proposed by the offshore wind project developer, Vineyard Wind in the City of New Bedford. The development is contingent on Commonwealth Wind being selected by the state (Buljan 2021). Town of Falmouth • The Town of Falmouth intends to improve street safety and accessibility for motorists, pedestrians, and bicyclists through the development of a Complete Streets Prioritization Plan. If approved, the project would be eligible for up to $400,000 in construction funding from MassDOT (Cape Cod Commission 2022). Town of Somerset • The Town of Somerset received $32,100 as part of the Shared Streets and Spaces Grant Program through Mass DOT to extend bike lanes to improve connections to the South Coast Bikeway (Town of Somerset 2022). • Brayton Point LLC Redevelopment Project proposed by Brayton Point LLC (2021). Martha's Vineyard • None identified.
	Rhode Island Town of Bristol • The Walley Beach/Halsey C. Herreshoff Park Seawall Repair project aims to restore the existing seawall along the seaside park. Proposed activities include replacing lost material and providing protective measures for the lawn. The project began in Spring 2021 and construction is ongoing (East Bay Rhode Island 2022). Town of Portsmouth • On May 20, 2021, a planned 3.16 MW, 18.3-acre solar project located on West Main Road in the Town of Portsmouth was approved by the town's Zoning Board of Review (West Main Solar 1, LLC 2021). Town of Tiverton • Two solar projects in the Town of Tiverton are currently in the planning stage: Brayton Road Solar and Cook Farm Solar Project. The Brayton Road Solar project received preliminary plan approval in 2021 and is expected to be approved by the Planning Board in 2022. The Cook Farm Solar project has received final plan approval from the Planning Board but has not begun construction (Newport Daily News 2021).
Port studies/ upgrades	*Massachusetts* • *Massachusetts Port Authority.* The Port of Massachusetts is implementing an $850 million port upgrade project to accommodate larger freight vessels. Project work includes dredging of Boston Harbor, constructing a new berth, and installing new ship-to-share cranes (Glenn 2021). • *Port of New Bedford.* The New Bedford Port Authority is conducting a $17 million project to expand the North Terminal at the Port of New Bedford, adding 150,000 square feet of terminal space. The bulkhead will be constructed using up to 97,000 yards of

Type	Description
	contaminated dredge material. Construction is anticipated to commence in May 2022 (Port of New Bedford 2022; Standard Times 2022).
	Rhode Island • *Point Judith, Port of Galilee, Rhode Island.* The Rhode Island Department of Environmental Management, which operates the Port of Galilee, a Narragansett-based commercial fishing port, is conducting four projects in 2022 in the north bulkhead area of the port totaling nearly $15 million in investments. The proposed Rhode Island Fiscal Year 2023 budget includes approximately $50 million in State Fiscal Recovery Funding to continue the work of upgrading essential infrastructure at the Port of Galilee. The proposed investment would fund the replacement of bulkheads and docks, water supply, electrical, and security upgrades, and improvements to bolster the port against the effects of climate change (Office of the Governor of Rhode Island 2022). • *Port of Davisville, Rhode Island.* The Rhode Island Fiscal Year 2023 budget includes $60 million and $35 million, respectively, for infrastructure upgrades to the Port of Davisville and the South Quay Marine Terminal in East Providence to support offshore wind activities on the U.S. East Coast. The funding for the Port of Davisville would support construction of the port's Terminal 5 Pier and completion of required dredging, preparation of about 34 acres to accommodate additional cargo laydown, and reconstruction and hardening of the existing surface of Pier 1 (Buljan 2022).
	Connecticut • *New London Heavy Lift Port.* The Connecticut Port Authority is conducting a project to redevelop the Port of New London State Pier as a heavy-lift capable port facility, in partnership with terminal operator Gateway Terminal, and joint venture partners Ørsted and Eversource. Heavy-lift capability would support various cargoes including wind turbine construction staging and pre-assembly, including construction support for the South Fork, Revolution Wind, and Sunrise offshore wind projects. Environmental permits for in-water work and onshore construction were issued in December 2021. Construction is anticipated to be completed by 1Q 2023 (Connecticut Port Authority 2021a; 2021b; CT Examiner 2022).
	Maryland • *Sparrows Point Port*. The Sparrows Point Container Terminal project will construct a new container terminal and intermodal yard located on 330 acres within the Tradepoint Atlantic industrial development site on Sparrows Point. In addition to onshore development, the project would include the widening and deepening of an existing channel and connection into the Brewerton Federal Navigation channel. USACE is currently preparing an EIS for the project (88 FR 87414).
	South Carolina • *Port of Charleston*. Construction is currently underway at the Port of Charleston on a near-dock rail-served cargo yard and inner-harbor barge operation. The $400 million Navy Base Intermodal Facility and $150 million inner-harbor barge operation includes the construction of almost 80,000 feet of rail track and will establish a designated marine highway to move shipping containers. Construction on the project is anticipated to be complete by July 2025 (South Carolina Ports Authority 2022).
	Texas

Type	Description
	• *Port of Corpus Christi*. The $681.6 million Channel Improvement Project to widen the channel to 530 feet and deepen to 54 feet is in the final construction phase and is estimated to be complete in early 2025 (Port of Corpus Christi 2023).

Attachment 1: Ongoing and Future Non-Offshore Wind Activity Analysis

This page intentionally left blank.

BOEM developed the following tables based on its 2019 study *National Environmental Policy Act Documentation for Impact-Producing Factors in the Offshore Wind Cumulative Impacts Scenario on the North Atlantic Outer Continental Shelf* (BOEM 2019), which evaluates potential impacts associated with ongoing and future non-offshore wind activities.

Table D1-1. Summary of activities and the associated impact-producing factors for air quality

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	Accidental releases of air toxics HAPs are due to potential chemical spills. Ongoing releases occur in low frequencies. These may lead to short-term periods of toxic pollutant emissions through surface evaporation. According to the U.S. Department of Energy, 31,000 barrels of petroleum are spilled into U.S. waters from vessels and pipelines in a typical year. Approximately 40.5 million barrels of oil were lost as a result of tanker incidents from 1970 to 2009, according to International Tanker Owners Pollution Federation Limited, which collects data on oil spills from tankers and other sources. From 1990 to 1999, the average annual input to the coastal Northeast was 220,000 barrels of petroleum and offshore it was up to less than 70,000 barrels.	Accidental releases of air toxics or HAPs will be due to potential chemical spills. Gradually increasing vessel traffic over the next 40 years would increase the risk of accidental releases. These may lead to short-term periods of toxic pollutant emissions through evaporation. Air quality impacts will be short-term and limited to the local area at and around the accidental release location.
Air emissions: Construction and decommissioning Air emissions: O&M Air emissions: Power generation emissions reductions	Air emissions originate from combustion engines and electric power generated by burning fuel. These activities are regulated under the CAA to meet set standards. Air quality has generally improved over the last 40 years; however, some areas in the Northeast have experienced a decline in air quality over the last 2 years. Some areas of the Atlantic coast remain in nonattainment for ozone, with the source of this pollution from power generation. Many of these states have made commitments toward cleaner energy goals to improve this, and offshore wind is part of these goals. Primary processes and activities that can affect the air quality impacts are expansions and modifications to existing fossil fuel power plants, onshore and offshore activities involving renewable energy facilities, and various construction activities.	Many Atlantic states have committed to clean energy goals, with offshore wind being a large part of that. Other reductions include transitioning to onshore wind and solar. The No Action Alternative without implementation of other future offshore wind projects would likely result in increased air quality impacts regionally due to the need to construct and operate new energy generation facilities to meet future power demands. These facilities may consist of new natural-gas-fired power plants, coal-fired, oil-fired, or clean-coal-fired plants. These types of facilities would likely have larger and continuous emissions and result in greater regional scale impacts on air quality.

CAA = Clean Air Act; hazmat = hazardous materials; HAPs = hazardous air pollutants

Table D1-2. Summary of activities and the associated impact-producing factors for bats

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded and would result in high-intensity, low-exposure level, long-term, but localized intermittent risk to bats in nearshore waters. Direct impacts are not expected to occur as recent research has shown that bats may be less sensitive to TTS than other terrestrial mammals (Simmons et al. 2016). Indirect impacts (i.e., displacement from potentially suitable habitats) could occur as a result of construction activities, which could generate noise sufficient to cause avoidance behavior (Schaub et al. 2008). Construction activity would be temporary and highly localized.	Similar to ongoing activities, noise associated with pile driving activities would be limited to nearshore waters, and these high-intensity, but low-exposure risks would not be expected to result in direct impacts. Some indirect impacts (i.e., displacement from potentially suitable foraging habitats) could occur as a result of construction activities, which could generate noise sufficient to cause avoidance behavior (Schaub et al. 2008). Construction activity would be temporary and highly localized, and no population-level effects would be expected.
Noise: Construction	Onshore construction occurs regularly for generic infrastructure projects in the bats geographic analysis area. There is a potential for displacement caused by equipment if construction occurs at night (Schaub et al. 2008). Any displacement would only be temporary. No individual or population level impacts would be expected. Some bats roosting in the vicinity of construction activities may be disturbed during construction but would be expected to move to a different roost farther from construction noise. This would not be expected to result in any impacts as frequent roost switching is a common component of a bat's life history (Hann et al. 2017; Whitaker 1998).	Onshore construction is expected to continue at current trends. Some behavioral responses and avoidance of construction areas may occur (Schaub et al. 2008). However, no injury or mortality would be expected.
Presence of structures: Migration disturbances	There may be few structures scattered throughout the offshore bats geographic analysis area, such as navigation and weather buoys and light towers. Migrating bats can easily fly around or over these sparsely distributed structures, and no migration disturbance would be expected. Bat use of offshore areas is very limited and generally restricted to spring and fall migration. Very few bats would be expected to encounter structures on the OCS and no population-level effects would be expected.	The infrequent installation of future new structures in the marine environment of the next 40 years is expected to continue. As described under Ongoing Activities, these structures would not be expected to cause disturbance to migrating tree bats in the marine environment.
Presence of structures: Turbine strikes	There may be few structures in the offshore bats geographic analysis area, such as navigation and weather buoys, turbines, and light towers. Migrating tree bats can easily fly around or over these sparsely distributed structures, and no strikes would be expected.	The infrequent installation of future new structures in the marine environment of the next 40 years is expected to continue. As described under Ongoing Activities, these structures would not be expected to result in increased collision risk to migrating tree bats in the marine environment.
Land disturbance: onshore construction	Onshore construction activities are expected to continue at current trends. Potential direct effects on individuals may occur if construction activities include tree removal when bats are potentially present. Injury or mortality may occur if trees being removed are occupied by bats at the time of removal. While there is some potential for indirect impacts associated with habitat loss, no individual or population-level effects would be expected.	Future non-offshore wind development would continue to occur at the current rate. This development has the potential to result in habitat loss and could result in injury or mortality of individuals.

Table D1-3. Summary of activities and the associated impact-producing factors for benthic resources

Associated IPFs: Sub-IFPs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See the Water Quality table for a discussion of ongoing accidental releases. Accidental releases of hazmat occur periodically, mostly consisting of fuels, lubricating oils, and other petroleum compounds. Because most of these materials tend to float in seawater, they rarely contact benthic resources. The chemicals with potential to sink or dissolve rapidly often dilute to non-toxic levels before they affect benthic resources. The corresponding impacts on benthic resources are rarely noticeable.	Gradually increasing vessel traffic over the next 40 years would increase the risk of accidental releases. See previous cell and the Water Quality table for details.
Accidental releases: Invasive species	Invasive species are periodically released accidentally during ongoing activities, including the discharge of ballast water and bilge water from marine vessels. The impacts on benthic resources (e.g., competitive disadvantage, smothering) depend on many factors, but can be noticeable, widespread, and permanent.	No future activities were identified within the geographic analysis area other than ongoing activities.
Accidental releases: Trash and debris	Ongoing releases of trash and debris occurs from onshore sources, fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, lines and pipeline laying. However, there does not appear to be evidence that ongoing releases have detectable impacts on benthic resources.	No future activities were identified within the geographic analysis area other than ongoing activities.
Anchoring	Regular vessel anchoring related to ongoing military, survey, commercial, and recreational activities continue to cause temporary to permanent impacts in the immediate area where anchors and chains meet the seafloor. These impacts include increased turbidity levels and the potential for direct contact to cause injury and mortality of benthic resources, as well as physical damage to their habitats. All impacts are localized; turbidity is temporary; injury and mortality are recovered in the short term; and physical damage can be permanent if it occurs in eelgrass beds or hard bottom.	No future activities were identified within the geographic analysis area other than ongoing activities.
EMFs	EMFs continuously emanate from existing telecommunication and electrical power transmission cables. New cables generating EMFs are infrequently installed in the geographic analysis area. Some benthic species can detect EMFs, although EMFs do not appear to present a barrier to movement. The extent of impacts (behavioral changes) is likely less than 50 feet (15.2 meters) from the cable and the intensity of impacts on benthic resources is likely undetectable.	No future activities were identified within the geographic analysis area other than ongoing activities.
Cable emplacement and maintenance	Cable maintenance activities infrequently disturb benthic resources and cause temporary increases in suspended sediment; these disturbances would be local and limited to the emplacement corridor. New cables are infrequently added near shore. Cable emplacement/maintenance activities injure and kill benthic resources, and result in temporary to long-term habitat alterations. The intensity of impacts depends on the time (season) and place (habitat type) where the activities occur. (See also the IPFs of Seabed profile alterations and Sediment deposition and burial.)	No future activities were identified within the geographic analysis area other than ongoing activities.
Noise: Onshore/offshore construction	See finfish, invertebrates, and EFH table. Detectable impacts of construction noise on benthic resources rarely, if ever, overlap from multiple sources.	See finfish, invertebrates, and EFH table. Detectable impacts of construction noise on benthic resources would rarely, if ever, overlap from multiple sources.
Noise: G&G	See finfish, invertebrates, and EFH table. Detectable impacts of G&G noise on benthic resources rarely, if ever, overlap from multiple sources.	See finfish, invertebrates, and EFH table. Detectable impacts of G&G noise on benthic resources would rarely, if ever, overlap from multiple sources.
Noise: O&M	See finfish, invertebrates, and EFH table.	See finfish, invertebrates, and EFH table.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can cause injury and/or mortality to benthic resources in a small area around each pile and can cause short-term stress and behavioral changes to individuals over a greater area. The extent depends on pile size, hammer energy, and local acoustic conditions.	No future activities were identified within the geographic analysis area other than ongoing activities.
Noise: Cable laying/trenching	Infrequent trenching activities for pipeline and cable laying, as well as other cable burial methods, emit noise. These disturbances are local, temporary, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	New or expanded submarine cables and pipelines are likely to occur in the geographic analysis area. These disturbances would be infrequent over the next 40 years, local, temporary, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.
Port utilization: Expansion	See finfish, invertebrates, and EFH table.	See finfish, invertebrates, and EFH table.

Associated IPFs: Sub-IFPs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear are periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. The lost gear, moved by currents, can disturb, injure, or kill benthic resources, creating small, short-term, localized impacts.	Future new cables would present additional risk of gear loss, resulting in small, short-term, localized impacts (disturbance, injury).
Presence of structures: Hydrodynamic disturbance	See finfish, invertebrates, and EFH table.	See finfish, invertebrates, and EFH table.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables continuously create uncommon relief in a mostly sandy seascape. Structure-oriented fishes are attracted to these locations. Increased predation upon benthic resources by structure-oriented fishes can adversely affect populations and communities of benthic resources. These impacts are local and permanent.	New cables installed in the geographic analysis area over the next 40 years would likely require hard protection atop portions of the route (see the "cable emplacement and maintenance" row in this table). Any new towers, buoy, or piers would also create uncommon relief in a mostly flat, sandy seascape. Structure-oriented fishes could be attracted to these locations. Increased predation upon benthic resources by structure-oriented fishes could adversely affect populations and communities of benthic resources. These impacts are expected to be local and to be permanent as long as the structures remain.
Presence of structures: Habitat conversion	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables continuously provide uncommon hard-bottom habitat. A large portion is homogeneous sandy seascape but there is some other hard and/or complex habitat. Benthic species dependent on hard-bottom habitat can benefit on a constant basis, although the new habitat can also be colonized by invasive species (e.g., certain tunicate species). Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitat to the new hard-structure habitat.	Any new towers, buoy, piers, or cable protection structures would create uncommon relief in a mostly sandy seascape. Benthic species dependent on hard-bottom habitat could benefit, although the new habitat could also be colonized by invasive species (e.g., certain tunicate species). Soft bottom is the dominant habitat type in the region, and species that rely on this habitat would not likely experience population-level impacts (Guida et al. 2017; Greene et al. 2010).
Presence of structures: Cable infrastructure	The presence of cable infrastructure, especially hard protection atop cables, causes impacts through entanglement/gear loss/damage, fish aggregation, and habitat conversion.	See other sub-IPFs within Presence of structures.
Discharges/intakes	The gradually increasing amount of vessel traffic is increasing the cumulative permitted discharges from vessels. Many discharges are required to comply with permitting standards established to ensure potential impacts on the environment are minimized or mitigated. However, there does not appear to be evidence that the volumes and extents have any impact on benthic resources.	There is the potential for new ocean dumping/dredge disposal sites in the Northeast. Impacts (disturbance, reduction in fitness) of infrequent ocean disposal to benthic resources are short-term because spoils are typically recolonized naturally. In addition, USEPA has established dredge spoil criteria and it regulates the disposal permits issued by USACE; these discharges are required to comply with permitting standards established to ensure potential impacts on the environment are minimized or mitigated.
Cable emplacement and maintenance: Seabed profile alterations	Ongoing sediment dredging for navigation purposes results in localized short-term impacts (habitat alteration, injury, and mortality) on benthic resources through this IPF. Dredging typically occurs only in sandy or silty habitats, which are abundant in the geographic analysis area and are quick to recover from disturbance. Therefore, such impacts, while locally intense, have little impact on benthic resources in the geographic analysis area.	No future activities were identified within the geographic analysis area other than ongoing activities.
Cable emplacement and maintenance: Sediment deposition and burial	Ongoing sediment dredging for navigation purposes results in fine sediment deposition. Ongoing cable maintenance activities also infrequently disturb bottom sediments; these disturbances are local, limited to the emplacement corridor. Sediment deposition could have adverse impacts on some benthic resources, especially eggs and larvae, including smothering and loss of fitness. Impacts may vary based on season/time of year. Where dredged materials are disposed, benthic resources are smothered. However, such areas are typically recolonized naturally in the short term. Most sediment dredging projects have time-of-year restrictions to minimize impacts on benthic resources. Most benthic resources in the geographic analysis area are adapted to the turbidity and periodic sediment deposition that occur naturally in the geographic analysis area.	USACE and/or private ports may undertake dredging projects periodically. Where dredged materials are disposed, benthic resources are buried. However, such areas are typically recolonized naturally in the short term. Most benthic resources in the geographic analysis area are adapted to the turbidity and periodic sediment deposition that occur naturally in the geographic analysis area.

EFH = Essential Fish Habitat; EMFs = electromagnetic fields; hazmat = hazardous materials

Table D1-4. Summary of activities and the associated impact-producing factors for birds

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See the Water Quality table for a quantitative analysis of these risks. Ongoing releases are frequent/chronic. Ingestion of hydrocarbons can lead to morbidity and mortality due to decreased hematological function, dehydration, drowning, hypothermia, starvation, and weight loss (Briggs et al. 1997; Haney et al. 2017; Paruk et al. 2016). Additionally, even small exposures that result in feather oiling can lead to sublethal effects that include changes in flight efficiencies and result in increased energy expenditure during daily and seasonal activities including chick provisioning, commuting, courtship, foraging, long-distance migration, predator evasion, and territory defense (Maggini et al. 2017). These impacts rarely result in population-level impacts.	Gradually increasing vessel traffic over the next 40 years would increase the potential risk of accidental releases and associated impacts, including mortality, decreased fitness, and health effects on individuals. Impacts are unlikely to affect populations.
Accidental releases: Trash and debris	Trash and debris are accidentally discharged through onshore sources; fisheries use; dredged material ocean disposal; marine minerals extraction; marine transportation, navigation, and traffic; survey activities; and cables, lines, and pipeline laying on an ongoing basis. In a study from 2010, students at sea collected more than 520,000 bits of plastic debris per square mile. In addition, many fragments come from consumer products blown out of landfills or tossed out as litter (Law et al. 2010). Birds may accidentally ingest trash mistaken for prey. Mortality is typically a result of blockages caused by both hard and soft plastic debris (Roman et al. 2019).	As population and vessel traffic increase gradually over the next 40 years, accidental release of trash and debris may increase. This may result in increased injury or mortality of individuals. However, there does not appear to be evidence that the volumes and extents would have any impact on bird populations.
Light: Vessels	Ocean vessels have an array of lights including navigational lights, deck lights, and interior lights. Such lights can attract some birds. The impact is localized and temporary. This attraction would not be expected to result in an increased risk of collision with vessels. Population-level impacts would not be expected.	Gradually increasing vessel traffic over the next 40 years would increase the potential for bird and vessel interactions. While birds may be attracted to vessel lights, this attraction would not be expected to result in increased risk of collision with vessels. No population-level impacts would be expected.
Light: Structures	Buoys, towers, and onshore structures with lights can attract birds. Onshore structures like houses and ports emit a great deal more light than offshore buoys and towers. This attraction has the potential to result in an increased risk of collision with lighted structures (Hüppop et al. 2006). Light from structures is widespread and permanent near the coast, but minimal offshore.	Light from onshore structures is expected to gradually increase in proportion with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Cable emplacement and maintenance	Cable emplacement and maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances will be temporary and generally limited to the emplacement corridor. Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances will be temporary and limited to the emplacement corridor. Suspended sediment could impair the vision of diving birds that are foraging in the water column (Cook and Burton 2010). However, given the localized nature of the potential impacts, individuals would be expected to successfully forage in nearby areas not affected by increased sedimentation and no biologically significant impacts on individuals or populations would be expected.	Future new cables, would occasionally disturb the seafloor and cause temporary increases in suspended sediment, resulting in localized, short-term impacts. Impacts would be temporary and localized, with no biologically significant impacts on individuals or populations.
Noise: Aircraft	Aircraft routinely travel in the geographic analysis area for birds. With the possible exception of rescue operations and survey aircraft, no ongoing aircraft flights would occur at altitudes that would elicit a response from birds. If flights are at a sufficiently low altitude, birds may flush, resulting in non-biologically significant increased energy expenditure. Disturbance, if any, would be localized and temporary and impacts would be expected to dissipate once the aircraft has left the area.	Aircraft noise is likely to continue to increase as commercial air traffic increases; however, very few flights would be expected to be at a sufficiently low altitude to elicit a response from birds. If flights are at a sufficiently low altitude, birds may flush, resulting in non-biologically significant increased energy expenditure. Disturbance, if any, would be localized and temporary and impacts would be expected to dissipate once the aircraft has left the area.
Noise: G&G	Infrequent site characterization surveys and scientific surveys produce high-intensity impulsive noise around sites of investigation. These activities could result in diving birds leaving the local area. Non-diving birds would be unaffected. Any displacement would only be temporary during non-migratory periods, but impacts could be greater if displacement were to occur in preferred feeding areas during seasonal migration periods.	Same as ongoing activities, with the addition of possible future oil and gas surveys.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water could result in intermittent, temporary, localized impacts on diving birds due to displacement from foraging areas if birds are present in the vicinity of pile-driving activity. The extent of these impacts depends on pile size, hammer energy, and local acoustic conditions. No biologically significant impacts on individuals or populations would be expected.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Noise: Onshore construction	Onshore construction is routinely used in generic infrastructure projects. Equipment could potentially cause displacement. Any displacement would only be temporary and no individual fitness or population-level impacts would be expected.	Onshore construction will continue at current trends. Some behavior responses could range from escape behavior to mild annoyance, but no individual injury or mortality would be expected.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Noise: Vessels	Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Sub-surface noise from vessels could disturb diving birds foraging for prey below the surface. The consequence to birds would be similar to noise from G&G but likely less because noise levels are lower.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Presence of structures: Entanglement, gear loss, gear damage	Each year, 2,551 seabirds die annually from interactions with U.S. commercial fisheries on the Atlantic (Sigourney et al. 2019). Even more die due to abandoned commercial fishing gear (nets). In addition, recreational fishing gear (hooks and lines) is periodically lost on existing buoys, pilings, hard protection, and other structures and has the potential to entangle birds.	No future activities were identified within the geographic analysis area for birds other than ongoing activities.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various hard protections atop cables create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these objects. These impacts are local and can be short-term to permanent. These fish aggregations can provide localized, short-term to permanent, beneficial impacts on some bird species because it could increase prey species availability.	New cables, installed incrementally in the geographic analysis area for birds over the next 20 to 40 years, would likely require hard protection atop portions of the cables (see cable emplacement and maintenance row). Any new towers, buoys, or piers would also create uncommon relief in a mostly flat seascape. Structure-oriented fishes could be attracted to these locations. Abundance of certain fishes may increase. These impacts are expected to be local and may be short-term to permanent. These fish aggregations can provide localized, short-term to permanent beneficial impacts on some bird species due to increased prey species availability.
Presence of structures: Migration disturbances	A few structures may be scattered about the offshore geographic analysis area for birds, such as navigation and weather buoys and light towers. Migrating birds can easily fly around or over these sparsely distributed structures.	The infrequent installation of future new structures in the marine or onshore environment over the next 40 years would not be expected to result in migration disturbances.
Presence of structures: Turbine strikes, displacement, and attraction	A few structures may be in the offshore geographic analysis area for birds, such as navigation and weather buoys, turbines, and light towers. Given the limited number of structures currently in the geographic analysis area, individual- and population-level impacts due to displacement from current foraging habitat would not be expected. Stationary structures in the offshore environment would not be expected to pose a collision risk to birds. Some birds like cormorants and gulls may be attracted to these structures and opportunistically roost on these structures.	The installation of future new structures in the marine or onshore environment over the next 40 years would not be expected to result in an increase in collision risk or to result in displacement. Some potential for attraction and opportunistic roosting exists but would be expected to be limited given the anticipated number of structures.
Traffic: Aircraft	General aviation accounts for approximately two bird strikes per 100,000 flights (Dolbeer et al. 2019). In addition to general aviation, aircraft are used for scientific and academic surveys in marine environments.	Bird fatalities associated with general aviation would be expected to increase with the current trend in commercial air travel. Aircraft will continue to be used to conduct scientific research studies as well as wildlife monitoring and pre-construction surveys. These flights would be well below the 100,000 flights and no bird strikes would be expected to occur.
Land disturbance: Onshore construction	Onshore construction activity will continue at current trends. There is some potential for indirect impacts associated with habitat loss and fragmentation.	Future non-offshore wind development would continue to occur at the current rate. This development has the potential to result in habitat loss but would not be expected to result in injury or mortality of individuals.

hazmat = hazardous materials

Table D1-5. Summary of activities and the associated impact-producing factors for coastal habitats and fauna

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See the Water Quality table for a discussion of ongoing accidental releases. Accidental releases of fuel/fluids/ hazmat have the potential to cause habitat contamination and harm to the species that build biogenic coastal habitats (e.g., eelgrass, oysters, mussels, slipper limpets, salt marsh cordgrass) from releases and/or cleanup activities. Only a portion of the ongoing releases contact coastal habitats in the geographic analysis area. Impacts are small, localized, and temporary.	See the Water Quality table for a discussion of accidental releases.
Accidental releases: Trash and debris	Ongoing releases of trash and debris occur from onshore sources, fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, lines and pipeline laying. As population and vessel traffic increase, accidental releases of trash and debris may increase. Such materials may be obvious when they come to rest on shorelines; however, there does not appear to be evidence that the volumes and extents would have any detectable impact on coastal habitats.	No future activities were identified within the geographic analysis area for coastal habitats other than ongoing activities.
Anchoring	Vessel anchoring related to ongoing military, survey, commercial, and recreational activities will continue to cause temporary to permanent impacts in the immediate area where anchors and chains meet the seafloor. These impacts include increased turbidity levels and potential for direct contact to cause physical damage to coastal habitats. All impacts are localized; turbidity is short-term and temporary; physical damage can be permanent if it occurs in eelgrass beds or hard bottom.	No future activities were identified within the geographic analysis area for coastal habitats other than ongoing activities.
EMF	EMFs continuously emanate from existing telecommunication and electrical power transmission cables. New cables generating EMFs are infrequently installed in the analysis area. The extent of impacts is likely less than 50 feet from the cable, and the intensity of impacts on coastal habitats is likely undetectable.	No future activities were identified within the geographic analysis area for coastal habitats other than ongoing activities.
Light: Vessels	Navigation lights and deck lights on vessels would be a source of ongoing light. The extent of impacts is limited to the immediate vicinity of the lights, and the intensity of impacts on coastal habitats is likely undetectable.	Light is expected to continue to increase gradually with increasing vessel traffic over the next 40 years. The extent of impacts would likely be limited to the immediate vicinity of the lights, and the intensity of impacts on coastal habitats would likely be undetectable.
Light: Structures	Ongoing lights from navigational aids and other structures onshore and nearshore. The extent of impacts is likely limited to the immediate vicinity of the lights, and the intensity of impacts on coastal habitats is likely undetectable.	No future activities were identified within the geographic analysis area for coastal habitats other than ongoing activities.
Cable emplacement and maintenance	Ongoing cable maintenance activities infrequently disturb bottom sediments; these disturbances are local and limited to the emplacement corridor (see the Sediment deposition and burial IPF).	No future activities were identified within the geographic analysis area other than ongoing activities.
Noise: Onshore/offshore construction	Ongoing noise from construction occurs frequently near shores of populated areas in New England and the mid-Atlantic, but infrequently offshore. Noise from construction near shore is expected to gradually increase over the next 40 years in line with human population growth along the coast of the geographic analysis area. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary.	No future activities were identified within the analysis area other than ongoing activities.
Noise: G&G	Site characterization surveys and scientific surveys are ongoing. The intensity and extent of the resulting impacts are difficult to generalize but are local and temporary.	Site characterization surveys, scientific surveys, and exploratory oil and gas surveys are anticipated to occur infrequently over the next 40 years. Site characterization surveys typically use sub-bottom profiler technologies that generate less-intense sound waves similar to common deep-water echosounders. The intensity and extent of the resulting impacts are difficult to generalize but are likely local and temporary.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can reach coastal habitats. The extent depends on pile size, hammer energy, and local acoustic conditions.	No future activities were identified within the analysis area other than ongoing activities.
Noise: Cable laying/trenching	Rare but ongoing trenching for pipeline and cable laying activities emits noise; cable burial via jet embedment also causes similar noise impacts. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise on coastal habitats are discountable compared to the impacts of the physical disturbance and sediment suspension.	New or expanded submarine cables and pipelines may occur in the geographic analysis area infrequently over the next 40 years. These disturbances would be temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise on coastal habitats are discountable compared to the impacts of the physical disturbance and sediment suspension.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Habitat conversion	Various structures, including pilings, piers, towers, riprap, buoys, and various means of hard protection, are periodically added to the seascape, creating uncommon relief in a mostly flat seascape and converting previously existing habitat (whether hard-bottom or soft-bottom) to a type of hard habitat, although it differs from the typical hard-bottom habitat in the analysis area, namely, coarse substrates in a sand matrix. The new habitat may or may not function similarly to hard-bottom habitat typical in the region (Kerckhof et al. 2019; HDR 2019). Soft bottom is the dominant habitat type on the OCS, and structures do not meaningfully reduce the amount of soft-bottom habitat available (Guida et al. 2017; Greene et al. 2010). Structures can also create an artificial reef effect, attracting a different community of organisms.	Any new cable or pipeline installed in the geographic analysis area would likely require hard protection atop portions of the route (see cells to the left). Such protection is anticipated to increase incrementally over the next 40 years. Where cables would be buried deeply enough that protection would not be used, presence of the cable would have no impact on coastal habitats.
Presence of structures: Transmission cable infrastructure	Various means of hard protection atop existing cables can create uncommon hard-bottom habitat. Where cables are buried deeply enough that protection is not used, presence of the cable has no impact on coastal habitats.	See above.
Land disturbance: Erosion and sedimentation	Ongoing development of onshore properties, especially shoreline parcels, periodically causes short-term erosion and sedimentation of coastal habitats.	No future activities were identified within the geographic analysis area other than ongoing activities.
Land disturbance: Onshore construction	Ongoing development of onshore properties, especially shoreline parcels, periodically causes short-term to permanent degradation of onshore coastal habitats.	No future activities were identified within the geographic analysis area other than ongoing activities.
Land disturbance: Onshore, land use changes	Ongoing development of onshore properties, especially shoreline parcels, periodically causes the conversion of onshore coastal habitats to developed space.	No future activities were identified within the geographic analysis area other than ongoing activities.
Cable emplacement and maintenance: Seabed profile alterations	Ongoing sediment dredging for navigation purposes results in localized, short-term impacts on coastal habitats through this IPF. Dredging typically occurs only in sandy or silty habitats, which are abundant in the analysis area and are quick to recover from disturbance. Therefore, such impacts, while locally intense, have little effect on the general character of coastal habitats.	No future activities were identified within the geographic analysis area other than ongoing activities.
Cable emplacement and maintenance: Sediment deposition and burial	Ongoing sediment dredging for navigation purposes results in fine sediment deposition within coastal habitats. Ongoing cable maintenance activities also infrequently disturb bottom sediments; these disturbances are local, limited to the emplacement corridor. No dredged material disposal sites were identified within the geographic analysis area.	No future activities were identified within the geographic analysis area other than ongoing activities.

hazmat = hazardous materials

Table D1-6. Summary of activities and the associated impact-producing factors for commercial fisheries and for-hire recreational fishing

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Anchoring	Impacts from anchoring occur due to ongoing military, survey, commercial, and recreational activities. The short-term, localized impact on this resource is the presence of a navigational hazard (anchored vessel) to fishing vessels.	Impacts from anchoring may occur on a semi-regular basis over the next 40 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. Anchoring could pose a temporary (hours to days), localized (within a few hundred meters of anchored vessel) navigational hazard to fishing vessels.
Cable emplacement and maintenance	New cable emplacement and infrequent cable maintenance activities disturb the seafloor, increase suspended sediment, and cause temporary displacement of fishing vessels. These disturbances would be local and limited to the emplacement corridor.	Future new cables and cable maintenance would occasionally disturb the seafloor and cause temporary displacement in fishing vessels and increases in suspended sediment resulting in local, short-term impacts. If the cable routes enter the geographic analysis area for this resource, short-term disruption of fishing activities would be expected.
Noise: Construction, trenching, operations and maintenance	Noise from construction occurs frequently in coastal habitats in populated areas in New England and the Mid-Atlantic, but infrequently offshore. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. Infrequent offshore trenching could occur in connection with cable installation. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Low levels of elevated noise from operational WTGs likely have low to no impacts on fish and no impacts at a fishery level. Noise is also created by O&M of marine minerals extraction, which has small, local impacts on fish, but likely no impacts at a fishery level.	Noise from construction near shore is expected to gradually increase in line with human population growth along the coast of the geographic analysis area for this resource. Noise from dredging and sand and gravel mining could occur. New or expanded marine minerals extraction may increase noise during their O&M over the next 40 years. Impacts from construction, operations, and maintenance would likely be small and local on fish, and not seen at a fishery level. Periodic trenching would be needed for repair or new installation of underground infrastructure. These disturbances would be temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise on commercial fish species are typically less prominent than the impacts of the physical disturbance and sediment suspension. Therefore, fishery-level impacts are unlikely.
Noise: G&G	Ongoing site characterization surveys and scientific surveys produce noise around sites of investigation. These activities can disturb fish and invertebrates in the immediate vicinity of the investigation and can cause temporary behavioral changes. The extent depends on equipment used, noise levels, and local acoustic conditions.	Site characterization surveys, scientific surveys, and exploratory oil and gas surveys are anticipated to occur infrequently over the next 40 years. Seismic surveys used in oil and gas exploration create high-intensity impulsive noise to penetrate deep into the seabed, potentially resulting in injury or mortality to finfish and invertebrates in a small area around each sound source and short-term stress and behavioral changes to individuals over a greater area. Site characterization surveys typically use sub-bottom profiler technologies that generate less-intense sound waves more similar to common deep-water echosounders. The intensity and extent of the resulting impacts are difficult to generalize but are likely local and temporary.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when ports or marinas, piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can cause injury and/or mortality to finfish and invertebrates in a small area around each pile and can cause short-term stress and behavioral changes to individuals over a greater area, leading to temporary local impacts on commercial fisheries and for-hire recreational fishing. The extent depends on pile size, hammer energy, and local acoustic conditions.	No future activities were identified in the analysis area other than ongoing activities.
Noise: Vessels	Vessel noise is anticipated to continue at levels similar to current levels. While vessel noise may have some impact on behavior, it is likely limited to brief startle and temporary stress responses. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels.	Planned new barge route and dredging disposal sites would generate vessel noise when implemented.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance, including dredging. Port utilization is expected to increase over the next 40 years.	Ports would need to perform maintenance and upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size. Port utilization is expected to increase over the next 40 years, with increased activity during construction. The ability of ports to receive the increase in vessel traffic may require port modifications, such as channel deepening, leading to local impacts on fish populations. Port expansions could also increase vessel traffic and competition for dockside services, which could affect fishing vessels.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Navigation hazard and allisions	Structures in and near the cumulative lease areas that pose potential navigation hazards include offshore wind turbines, buoys, and shoreline developments such as docks and ports. An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. Two types of allisions occur: drift and powered. A drift allision generally occurs when a vessel is powered down due to operator choice or power failure. A powered allision generally occurs when an operator fails to adequately control their vessel movements or is distracted.	No known reasonably foreseeable structures are proposed to be located in the geographic analysis area that could affect commercial fisheries. Vessel allisions with non-offshore wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. The lost gear, moved by currents, can disturb habitats and potentially harm individuals, creating small, localized, short-term impacts on fish, but likely no impacts at a fishery level.	No future activities were identified in the analysis area other than ongoing activities.
Presence of structures: Habitat conversion and fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly sandy seascape. A large portion is homogeneous sandy seascape but there is some other hard and/or complex habitat. Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitat to the new hard-structure habitat. Structure-oriented fishes are attracted to these locations. These impacts are local and can be short-term to permanent. Fish aggregation may be considered adverse, beneficial, or neither. Commercial and for-hire recreational fishing can occur near these structures. For-hire recreational fishing is more popular, as commercial mobile fishing gear risk snagging on the structures.	New cables, installed incrementally in the analysis area over the next 20 to 40 years, would likely require hard protection atop portions of the route (see cable emplacement and maintenance IPF above). Any new towers, buoys, or piers would also create uncommon relief in a mostly flat seascape. Structure-oriented species could be attracted to these locations. Structure-oriented species would benefit (Claisse et al. 2014; Smith et al. 2016). This may lead to more and larger structure-oriented fish communities and larger predators opportunistically feeding on the communities, as well as increased private and for-hire recreational fishing opportunities. Soft bottom is the dominant habitat type in the region, and species that rely on this habitat would not likely experience population-level impacts (Guida et al. 2017; Greene et al. 2010). These impacts are expected to be local and may be long term.
Presence of structures: Migration disturbances	Human structures in the marine environment, e.g., shipwrecks, artificial reefs, buoys, and oil platforms, can attract finfish and invertebrates that approach the structures during their migrations. This could slow species migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement than structure (Secor et al. 2018). There is no evidence to suggest that structures pose a barrier to migratory animals.	The infrequent installation of future new structures in the marine environment over the next 40 years may attract finfish and invertebrates that approach the structures during their migrations. This could tend to slow migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement (Secor et al. 2018). Migratory animals would likely be able to proceed from structures unimpeded. Therefore, fishery-level impacts are not anticipated.
Presence of structures: Space use conflicts	Current structures do not result in space use conflicts.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Presence of structures: Cable infrastructure	The existing offshore cable infrastructure supports the economy by transmitting electric power and communications between mainland and islands. Shoreline developments are ongoing and include docks, ports, and other commercial, industrial, and residential structures.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Traffic: Vessels and vessel collisions	No substantial changes are anticipated to the vessel traffic volumes. The geographic analysis area would continue to have numerous ports and the extensive marine traffic related to shipping, fishing, and recreation would continue to be important to the region’s economy. The region’s substantial marine traffic may result in occasional collisions. Vessels need to navigate around structures to avoid allisions. When multiple vessels need to navigate around a structure, then navigation is more complex, as the vessels need to avoid both the structure and each other. The risk for collisions is ongoing but infrequent.	New vessel traffic in the geographic analysis area would consistently be generated by proposed barge routes and dredging demolition sites. Marine commerce and related industries would continue to be important to the regional economy.

Table D1-7. Summary of activities and the associated impact-producing factors for cultural resources

Associated IPF: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See the Water Quality table for water quality for a quantitative analysis of these risks. Accidental releases of fuel/fluids/hazmat occur during vessel use for recreational, fisheries, marine transportation, or military purposes, and other ongoing activities. Both released fluids and cleanup activities that require the removal of contaminated soils and/or seafloor sediments can cause impacts on cultural resources because resources are affected during by the released chemicals as well as the ensuing cleanup activities.	Gradually increasing vessel traffic over the next 40 years would increase the risk of accidental releases within the geographic analysis area for cultural resources, increasing the frequency of small releases. Although the majority of anticipated accidental releases would be small, resulting in small-scale impacts on cultural resources, a single, large-scale accidental release such as an oil spill, could have significant impacts on marine and coastal cultural resources. A large-scale release would require extensive cleanup activities to remove contaminated materials resulting in damage to or the complete removal of terrestrial and marine cultural resources. In addition, the accidentally released materials in deep water settings could settle on seafloor cultural resources such as wreck sites, accelerating their decomposition and/or covering them and making them inaccessible/unrecognizable to researchers, resulting in a significant loss of historic information. As a result, although considered unlikely, a large-scale accidental release and associated cleanup could result in permanent, geographically extensive, and large-scale impacts on cultural resources.
Accidental releases: Trash and debris	Accidental releases of trash and debris occur during vessel use for recreational, fisheries, marine transportation, or military purposes and other ongoing activities. While the released trash and debris can directly affect cultural resources, the majority of impacts associated with accidental releases occur during cleanup activities, especially if soil or sediment removed during cleanup affect known and undiscovered archaeological resources. In addition, the presence of large amounts of trash on shorelines or the ocean surface can impact the cultural value of Traditional Cultural Properties (TCPs) for stakeholders. State and federal laws prohibiting large releases of trash would limit the size of any individual release and ongoing local, state, and federal efforts to clean up trash on beaches and waterways would continue to mitigate the effects of small-scale accidental releases of trash.	Future activities with the potential to result in accidental releases include construction and operations of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications). Accidental releases would continue at current rates along the northeast Atlantic coast.
Anchoring	The use of vessel anchoring and gear (i.e., wire ropes, cables, chain, sweep on the seafloor) that disturbs the seafloor, such as bottom trawls and anchors, by military, recreational, industrial, and commercial vessels can impact cultural resources by physically damaging maritime archaeological resources such as shipwrecks and debris fields.	Future activities with the potential to result in anchoring/gear utilization include construction and operations of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); military use; marine transportation; fisheries use and management; and oil and gas activities. These activities are likely to continue to occur at current rates along the entire coast of the eastern United States.
Gear utilization: Dredging	Activities associated with dredge operations and activities could damage marine archaeological resources. Ongoing activities identified by BOEM with the potential to result in dredging impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); tidal energy projects; marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities.	Dredging activities would gradually increase through time as new offshore infrastructure is built, such as gas pipelines and electrical lines, and as ports and harbors are expanded or maintained.
Light: Vessels	Light associated with military, commercial, or construction vessel traffic can temporarily affect coastal historic structures and TCP resources when the addition of intrusive, modern lighting changes the physical environment ("setting") of cultural resources. The impacts of construction and operational lighting would be limited to cultural resources on the shoreline for which a nighttime sky is a contributing element to historic integrity. This excludes resources that are closed at night, such as historic buildings, lighthouses, and battlefields, and resources that generate their own nighttime light, such as historic districts. Offshore construction activities that require increased vessel traffic, construction vessels stationed offshore, and construction area lighting for prolonged periods can cause more sustained and significant visual impacts on coastal historic structure and TCP resources.	Future activities with the potential to result in vessel lighting impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Light pollution from vessel traffic would continue at the current intensity along the northeast coast, with a slight increase due to population increase and development over time.
Light: Structures	The construction of new structures that introduce new light sources into the setting of historic architectural properties or TCPs can result in impacts, particularly if the historic and/or cultural significance of the resource is associated with uninterrupted nighttime skies or periods of darkness. Any tall structure (commercial building, radio antenna, large satellite dishes, etc.) requiring nighttime hazard lighting to prevent aircraft collision can cause these types of impacts.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.

Associated IPF: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Port utilization: Expansion	Major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. Expansion of port facilities can introduce large, modern port infrastructure into the viewsheds of nearby historic properties, affecting their setting and historic significance.	Future activities with the potential to result in port expansion impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); tidal energy projects; marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Port expansion would continue at current levels, which reflect efforts to capture business associated with the offshore wind industry (irrespective of specific projects).
Presence of structures	The only existing offshore structures within the viewshed of the geographic analysis area are minor features such as buoys.	Non-offshore wind structures that could be viewed would be limited to meteorological towers. Marine activity would also occur within the marine viewshed of the geographic analysis area.
Cable emplacement and maintenance	Infrequent cable maintenance activities disturb the seafloor and could cause impacts on submerged archaeological resources. These disturbances would be local and limited to emplacement corridors.	Future activities with the potential to result in seafloor disturbances similar to offshore impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); tidal energy projects; marine minerals use and ocean-dredged material disposal; military use; and oil and gas activities. Such activities could cause impacts on submerged archaeological resources including shipwrecks and formerly subaerially exposed pre-contact Native American archaeological sites.
Land disturbance: Onshore construction	Onshore construction activities can impact archaeological resources by damaging and/or removing resources.	Future activities that could result in terrestrial land disturbance impacts include onshore residential, commercial, industrial, and military development activities along the East Coast, particularly those proximate to export cables and interconnection facilities. Onshore construction would continue at current rates.

hazmat = hazardous materials; TCPs = Traditional Cultural Resources

Table D1-8. Summary of activities and the associated impact-producing factors for demographics, employment, and economics

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Light: Structures	Offshore buoys and towers emit low-intensity light, while onshore structures, including houses and ports, emit substantially more light on an ongoing basis.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Light: Vessels	Ocean vessels have an array of lights including navigational lights and deck lights.	Anticipated modest growth in vessel traffic would result in some growth in the nighttime traffic of vessels with lighting.
Cable emplacement and maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances would be local and limited to emplacement corridors. In the geographic analysis area for demographics, employment, and economics there are six existing power cables.	Future new cables would disturb the seafloor and cause temporary increases in suspended sediment resulting in infrequent, localized, short-term impacts over the next 40 years.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. These disturbances are temporary, local, and extend only a short distance beyond the work area.	No future activities were identified within the geographic analysis area for demographics, employment, and economics other than ongoing activities.
Noise: Cable laying/trenching	Infrequent trenching for pipeline and cable laying activities emit noise. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	Periodic trenching would be needed over the next 40 years for repair or new installation of underground infrastructure.
Noise: Vessels	Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels.	Planned new barge route and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. The New Jersey Wind Port is being developed and the Port of Paulsboro (New Jersey) and Port of New London (Connecticut) are being upgraded specifically to support the construction of offshore wind energy facilities.	Ports would need to perform maintenance and upgrade facilities over the next 40 years to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.
Port utilization: Maintenance/dredging	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. As ports expand, maintenance dredging of shipping channels is expected to increase.	Ports would need to perform maintenance and upgrades over the next 40 years to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.
Presence of structures: Allisions	An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. The likelihood of allisions is expected to continue at or near current levels.	Vessel allisions with non-offshore wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. Such loss and damage are direct costs for gear owners and are expected to continue at or near current levels.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these locations, which may be known as fish aggregation devices (FADs). Recreational and commercial fishing can occur near the FADs, although recreational fishing is more popular, because commercial mobile fishing gear is more likely to snag on FADs.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Habitat conversion	Structures, including foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly flat seascape. Structure-oriented species thus benefit on a constant basis.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure, because vessels need to avoid both the structure and each other.	Vessel traffic, overall, is not expected to meaningfully increase over the next 40 years. The presence of navigation hazards is expected to continue at or near current levels.
Presence of structures: Space use conflicts	Current structures do not result in space use conflicts.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Viewshed	No existing offshore structures are within the viewshed of the offshore wind lease area except buoys.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Transmission cable infrastructure	The existing offshore cable infrastructure supports the economy by transmitting electric power and communications between mainland and islands. Additional communication cables run between the U.S. East Coast and European countries along the eastern Atlantic.	No known proposed structures not associated with offshore wind development are reasonably foreseeable.
Traffic: Vessels	Ports and marine traffic related to shipping, fishing, and recreation are important to the region's economy. No substantial changes are anticipated to existing vessel traffic volumes.	New vessel traffic near the geographic analysis area would be generated by proposed barge routes and dredging demolition sites over the next 40 years. Marine commerce and related industries would continue to be important to the geographic analysis area economy.
Traffic: Vessel collisions	The region's substantial marine traffic may result in occasional vessel collisions, which would result in costs to the vessels involved. The likelihood of collisions is expected to continue at or near current rates.	No substantial changes anticipated.
Land disturbance: Onshore construction	Onshore development activities support local population growth, employment, and economies. Disturbances can cause temporary, localized traffic delays and restricted access to adjacent properties. The rate of onshore land disturbance is expected to continue at or near current rates.	Onshore development projects would be ongoing in accordance with local government land use plans and regulations.

FADs = fish aggregating devices

Table D1-9. Summary of activities and the associated impact-producing factors for environmental justice

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Air emissions: Construction/decommissioning	Ongoing population growth and new development within the analysis area is likely to increase traffic with resulting increase in emissions from motor vehicles. Some new industrial development may result in emissions-producing uses. At the same time, many industrial waterfront areas near environmental justice communities are losing industrial uses and converting to more commercial or residential uses.	New development may include emissions-producing industry and new development that would increase emissions from motor vehicles. Some historically industrial waterfront locations will continue to lose industrial uses, with no new industrial development to replace it.
Air emissions: Operations and maintenance	Ongoing population growth and new development within the analysis area is likely to increase traffic with resulting increase in emissions from motor vehicles. Some new industrial development may result in emissions-producing uses. At the same time, many industrial waterfront areas near environmental justice communities are losing industrial uses and converting to more commercial or residential uses.	New development may include emissions-producing industry and new development that would increase emissions from motor vehicles. Some historically industrial waterfront locations will continue to lose industrial uses, with no new industrial development to replace it.
Light: Structures	Offshore buoys and towers emit low-intensity light, while onshore structures, including houses and ports, emit substantially more light on an ongoing basis.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Cable emplacement and maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances would be local and limited to emplacement corridors.	Future new cables would disturb the seafloor and cause temporary increases in suspended sediment, resulting in infrequent, localized, short-term impacts over the next 40 years.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. These disturbances are temporary, local, and extend only a short distance beyond the work area.	No future activities were identified within the analysis area other than ongoing activities.
Noise: Trenching	Infrequent trenching for pipeline and cable laying activities emits noise. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	Periodic trenching would be needed over the next 40 years for repair or new installation of underground infrastructure.
Noise: Vessels	Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels.	Vessel noise is anticipated to continue at or near current levels.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. The New Jersey Wind Port is being developed and the Port of Paulsboro and Port of New London are being upgraded specifically to support the construction of offshore wind energy facilities.	Ports would need to perform maintenance and upgrade facilities to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.
Presence of structures: Entanglement, gear loss/damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. Such loss and damage are direct costs for gear owners and are expected to continue at or near current levels.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure, because vessels need to avoid both the structure, and each other.	Vessel traffic is generally not expected to meaningfully increase over the next 40 years. The presence of navigation hazards is expected to continue at or near current levels.
Presence of structures: Space use conflicts	Current structures do not result in space use conflicts.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Viewshed	There are no existing offshore structures within the viewshed of the offshore wind lease area except buoys.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Cable infrastructure	Existing submarine cables cross cumulative lease areas.	Existing cable O&M activities would continue within the analysis area.
Traffic: Vessels	Ports and marine traffic related to shipping, fishing and recreation are important to the region’s economy. No substantial changes are anticipated to existing vessel traffic volumes.	Vessel traffic is not expected to meaningfully increase over the next 40 years. Marine commerce and related industries would continue to be important to area employment.
Land disturbance: Erosion and sedimentation	Potential erosion and sedimentation from development and construction is controlled by local and state development regulations.	New development activities would be subject to erosion and sedimentation regulations.
Land disturbance: Onshore construction	Onshore development supports local population growth, employment, and economics.	Onshore development would continue in accordance with local government land use plans and regulations.
Land disturbance: Onshore, land use changes	Onshore development would result in changes in land use in accordance with local government land use plans and regulations.	Development of onshore solar and wind energy would provide diversified, small-scale energy generation.

Table D1-10. Summary of activities and the associated impact-producing factors for finfish, invertebrates, and essential fish habitat

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See the Water Quality table for a quantitative analysis of these risks. Ongoing releases are frequent/chronic. Impacts, including mortality, decreased fitness, and contamination of habitat, are localized and temporary, and rarely affect populations.	Gradually increasing vessel traffic over the next 40 years would increase the risk of accidental releases. Impacts are unlikely to affect populations.
Accidental releases: Invasive species	Invasive species are periodically released accidentally during ongoing activities, including the discharge of ballast water and bilge water from marine vessels. The impacts on finfish, invertebrates, and EFH depend on many factors, but can be widespread and permanent.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Anchoring	Vessel anchoring related to ongoing military use, and survey, commercial, and recreational activities continue to cause temporary to permanent impacts in the immediate area where anchors and chains meet the seafloor. Impacts on finfish, invertebrates, and EFH are greatest for sensitive EFH (e.g., eelgrass, hard bottom) and sessile or slow-moving species (e.g., corals, sponges, and sedentary shellfish).	Impacts from anchoring may occur on a semi-regular basis over the next 40 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. These impacts would include increased turbidity levels and potential for direct contact causing mortality of benthic species and, possibly, degradation of sensitive habitats. All impacts would be localized; turbidity would be temporary; impacts from direct contact would be recovered in the short term. Degradation of sensitive habitats such as certain types of hard bottom (e.g., boulder piles), if it occurs, could be long term.
EMF	EMF emanates continuously from installed telecommunication and electrical power transmission cables. Biologically significant impacts on finfish, invertebrates, and EFH have not been documented for AC cables (CSA Ocean Sciences, Inc. and Exponent 2019; Thomsen et al. 2015), but behavioral impacts have been documented for benthic species (skates and lobster) near operating DC cables (Hutchison et al. 2018). The impacts are localized and affect the animals only while they are within the EMF. There is no evidence to indicate that EMF from undersea AC power cables negatively affects commercially and recreationally important fish species (CSA Ocean Sciences, Inc. and Exponent 2019).	During operation, future new cables would produce EMF. Submarine power cables in the geographic analysis area are assumed to be installed with appropriate shielding and burial depth to reduce potential EMF to low levels. Although the EMF would exist as long as a cable was in operation, impacts, on finfish, invertebrates, and EFH would likely be difficult to detect.
Light: Vessels	Marine vessels have an array of lights including navigational lights and deck lights. There is little downward-focused lighting, and therefore only a small fraction of the emitted light enters the water. Light can attract finfish and invertebrates, potentially affecting distributions in a highly localized area. Light may also disrupt natural cycles, e.g., spawning, possibly leading to short-term impacts.	Vessels would continue to be a light source within the analysis area.
Light: Structures	Offshore buoys and towers emit light, and onshore structures, including buildings and ports, emit a great deal more on an ongoing basis. Light can attract finfish and invertebrates, potentially affecting distributions in a highly localized area. Light may also disrupt natural cycles, e.g., spawning, possibly leading to short-term impacts. Light from structures is widespread and permanent near the coast, but minimal offshore.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Cable emplacement and maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances are local, limited to the cable corridor. New cables are infrequently added near shore. Cable emplacement/maintenance activities disturb, displace, and injure finfish and invertebrates and result in temporary to long-term habitat alterations. The intensity of impacts depends on the time (season) and place (habitat type) where the activities occur. (See also the IPF of Sediment deposition and burial.)	Future new cables would occasionally disturb the seafloor and cause temporary increases in suspended sediment, resulting in local short-term impacts. If the cable routes enter the geographic analysis area for this resource, short-term disturbance would be expected. The intensity of impacts would depend on the time (season) and place (habitat type) where the activities would occur.
Noise: Aircraft	Noise from aircraft reaches the sea surface on a regular basis. However, there is not likely to be any impact of aircraft noise on finfish, invertebrates, and EFH, as very little of the aircraft noise propagates through the water.	Aircraft noise is likely to continue to increase as commercial air traffic increases. However, there is not likely to be any impact of aircraft noise on finfish, invertebrates, and EFH.
Noise: Onshore/offshore construction	Noise from construction occurs frequently in near shores of populated areas in New England and the mid-Atlantic but infrequently offshore. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. See also sub-IPF for Noise: Pile driving.	Noise from construction near shores is expected to gradually increase in line with human population growth along the coast of the geographic analysis area for this resource.
Noise: G&G	Ongoing site characterization surveys and scientific surveys produce noise around sites of investigation. These activities can disturb finfish and invertebrates in the immediate vicinity of the investigation and can cause temporary behavioral changes. The extent depends on equipment used, noise levels, and local acoustic conditions.	Site characterization surveys, scientific surveys, and exploratory oil and gas surveys are anticipated to occur infrequently over the next 40 years. Seismic surveys used in oil and gas exploration create high-intensity impulsive noise to penetrate deep into the seabed, potentially resulting in injury or mortality to finfish and invertebrates in a small area around each sound source and short-term stress and behavioral changes to individuals over a greater area. Site characterization surveys typically use sub-bottom profiler technologies that generate less-intense sound waves more similar to common deep-water echosounders. The intensity and extent of the resulting impacts are difficult to generalize but are likely local and temporary.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Noise: O&M	Some finfish and invertebrates may be able to hear the continuous underwater noise of operational WTGs. As measured at the Block Island Wind Farm, this low frequency noise barley exceeds ambient levels at 164 feet (50 meters) from the WTG base. Based on the results of Thomsen et al. (Thomsen et al. 2015), SPLs would be expected to be at or below ambient levels at relatively short distances (approximately 164 feet [50 meters]) from WTG foundations. These low levels of elevated noise likely have little to no impact. Noise is also created by O&M of marine minerals extraction and commercial fisheries, each of which has small local impacts.	New or expanded marine minerals extraction and commercial fisheries may intermittently increase noise during their O&M over the next 40 years. Impacts would likely be small and local.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can cause injury and/or mortality to finfish and invertebrates in a small area around each pile and can cause short-term stress and behavioral changes to individuals over a greater area. Eggs, embryos, and larvae of finfish and invertebrates could also experience developmental abnormalities or mortality resulting from this noise, although thresholds of exposure are not known (Weilgart 2018; Hawkins and Popper 2017). Potentially injurious noise could also be considered as rendering EFH temporarily unavailable or unsuitable for the duration of the noise. The extent depends on pile size, hammer energy, and local acoustic conditions.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Noise: Cable laying/trenching	Infrequent trenching activities for pipeline and cable laying, as well as other cable burial methods, emit noise. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.	New or expanded submarine cables and pipelines are likely to occur in the geographic analysis area for this resource. These disturbances would be infrequent over the next 40 years, temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension.
Noise: Vessels	While ongoing vessel noise may have some effect on behavior, it is likely limited to brief startle and temporary stress responses. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels.	See cell to the left.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance, including dredging. Port utilization is expected to increase over the next 40 years.	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and may continue to increase in the foreseeable future. In addition, the general trend along the coast from South Carolina to Maine is that port activity will increase modestly. The ability of ports to receive the increase may require port modifications, leading to local impacts. Future channel deepening activities will likely be undertaken. Existing ports have already affected finfish, invertebrates, and EFH, and future port projects would implement BMPs to minimize impacts. Although the degree of impacts on EFH would likely be undetectable outside the immediate vicinity of the ports, adverse impacts on EFH for certain species and/or life stages may lead to impacts on finfish and invertebrates beyond the vicinity of the port.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. The lost gear, moved by currents, can disturb habitats and potentially harm individuals, creating small, localized, short-term impacts.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Presence of structures: Hydrodynamic disturbance	Manmade structures, especially tall vertical structures such as foundations for towers of various purposes, continuously alter local water flow at a fine scale. Water flow typically returns to background levels within a relatively short distance from the structure. Therefore, impacts on finfish, invertebrates, and EFH are typically undetectable. Indirect impacts of structures influencing primary productivity and higher trophic levels are possible but are not well understood. New structures are periodically added.	Tall vertical structures can increase seabed scour and sediment suspension. Impacts would likely be highly localized and difficult to detect. Indirect impacts of structures influencing primary productivity and higher trophic levels are possible but are not well understood.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly sandy seascape. Structure-oriented fishes are attracted to these locations. These impacts are local and often permanent. Fish aggregation may be considered adverse, beneficial, or neutral.	New cables, installed incrementally in the geographic analysis area for this resource over the next 20 to 40 years, would likely require hard protection atop portions of the route (see the cable emplacement and maintenance IPF). Any new towers, buoys, or piers would also create uncommon relief in a mostly sandy seascape. Structure-oriented fishes could be attracted to these locations. Abundance of certain fishes may increase. These impacts are local and may be permanent.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Habitat conversion	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly sandy seascape. A large portion is homogeneous sandy seascape but there is some other hard and/or complex habitat. Structure-oriented species thus benefit on a constant basis; however, the diversity may decline over time as early colonizers are replaced by successional communities dominated by blue mussels and anemones (Degraer et al. 2019 [Chapter 7]). Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitat to the new hard-structure habitat.	New cable, installed incrementally in the analysis area over the next 20 to 40 years, would likely require hard protection atop portions of the route (see cable emplacement and maintenance). Any new towers, buoys, or piers would also create uncommon relief in a mostly sandy seascape. Structure-oriented species would benefit (Claisse et al. 2014; Smith et al. 2016); however, the diversity may decline over time as early colonizers are replaced by successional communities dominated by blue mussels and anemones (Degraer et al. 2019 [Chapter 7]). Soft bottom is the dominant habitat type from Cape Hatteras to the Gulf of Maine (over 60 million acres), and species that rely on this habitat would not likely experience population-level impacts (Guida et al. 2017; Greene et al. 2010).
Presence of structures: Migration disturbances	Human structures in the marine environment, e.g., shipwrecks, artificial reefs, and oil platforms, can attract finfish and invertebrates that approach the structures during their migrations. This could slow migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement than structure is (Moser and Shepherd 2009; Fabrizio et al. 2014; Secor et al. 2018). There is no evidence to suggest that structures pose a barrier to migratory animals.	The infrequent installation of future new structures in the marine environment over the next 40 years may attract finfish and invertebrates that approach the structures during their migrations. This could tend to slow migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement (Moser and Shepherd 2009; Fabrizio et al. 2014; Secor et al. 2018). Migratory animals would likely be able to proceed from structures unimpeded.
Presence of structures: Cable infrastructure	See other sub-IPFs within the Presence of structures IPF. See table for Coastal Habitats and Fauna.	See other sub-IPFs within the Presence of structures IPF. See table for Coastal Habitats and Fauna.
Cable emplacement and maintenance: Seabed profile alterations	Ongoing sediment dredging for navigation purposes results in localized short-term impacts (habitat alteration, change in complexity) on finfish, invertebrates, and EFH through this IPF. Dredging is most likely in sand wave areas where typical jet plowing is insufficient to meet target cable burial depth. Sand waves that are dredged would likely be redeposited in like-sediment areas. Any particular sand wave may not recover to the same height and width as pre-disturbance; however, the habitat function would largely recover post-disturbance. Therefore, seabed profile alterations, while locally intense, have little impact on finfish, invertebrates, and EFH on a regional (Cape Hatteras to Gulf of Maine) scale.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.
Cable emplacement and maintenance: Sediment deposition and burial	Ongoing sediment dredging for navigation purposes results in fine sediment deposition. Ongoing cable maintenance activities also infrequently disturb bottom sediments; these disturbances are local, limited to the emplacement corridor. Sediment deposition could have negative impacts on eggs and larvae, particularly demersal eggs such as longfin squid, which are known to have high rates of egg mortality if egg masses are exposed to abrasion or burial. Impacts may vary based on season/time of year.	No future activities were identified within the geographic analysis area for this resource other than ongoing activities.

AC = alternating current; DC = direct current; EFH = Essential Fish Habitat; EMF = electromagnetic field; hazmat = hazardous materials; SPLs = sound pressure levels

Table D1-11. Summary of activities and the associated impact-producing factors for land use and coastal infrastructure

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	Various ongoing onshore and coastal construction projects include the use of vehicles and equipment that contain fuel, fluids, and hazardous materials that could be released.	Ongoing onshore construction projects involve vehicles and equipment that use fuel, fluids, or hazardous materials could result in an accidental release. Intensity and extent would vary, depending on the size, location, and materials involved in the release.
Light: Structures	Various ongoing onshore and coastal construction projects have nighttime activities, as well as existing structures, facilities, and vehicles that would use nighttime lighting.	Ongoing onshore construction projects involving nighttime activity could generate nighttime lighting. Intensity and extent would vary, depending on the location, type, direction, and duration of nighttime lighting.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. The New Jersey Wind Port is being developed and the Port of Paulsboro and Port of New London being upgraded specifically to support the construction of offshore wind energy facilities.	Ports would need to perform maintenance and upgrade facilities to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep draft vessels as they continue to increase in size.
Presence of structures: Viewshed	The only existing offshore structures within the offshore viewshed are minor features such as buoys.	Non-offshore wind structures that could be viewed in conjunction with the offshore components would be limited to met towers. Marine activity would also occur within the marine viewshed.
Presence of structures: Cable infrastructure	Onshore buried cables would only occur where permitted by local land use authorities, which would avoid long-term land use conflicts.	No known proposed structures are reasonably foreseeable and proposed to be located in the geographic analysis area for land use and coastal infrastructure.
Land disturbance: Onshore construction	Onshore construction supports local population growth, employment, and economics.	Onshore development would continue in accordance with local government land use plans and regulations.
Land disturbance: Onshore, land use changes	New development or redevelopment would result in changes in land use in accordance with local government land use plans and regulations.	Ongoing and future development and redevelopment is anticipated to reinforce existing land use patterns, based on local government planning documents.

hazmat = hazardous materials; met = meteorological

Table D1-12. Summary of activities and the associated impact-producing factors for marine mammals

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See the Water Quality table for a quantitative analysis of these risks. Ongoing releases are frequent/ chronic. Marine mammal exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality or sublethal effects on the individual fitness, including adrenal effects, hematological effects, liver effects lung disease, poor body condition, skin lesions, and several other health affects attributed to oil exposure (Kellar et al. 2017; Mazet et al. 2001; Mohr et al. 2008; Smith et al. 2017; Sullivan et al. 2019; Takeshita et al. 2017). Additionally, accidental releases may result in impacts on marine mammals due to effects on prey species (see Finfish, Invertebrates, and Essential Fish Habitat table).	Gradually increasing vessel traffic over the next 40 years would increase the risk of accidental releases. Marine mammal exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality or sublethal effects on the individual fitness, including adrenal effects, hematological effects, liver effects lung disease, poor body condition, skin lesions, and several other health affects attributed to oil exposure (Kellar et al. 2017; Mazet et al. 2001; Mohr et al. 2008; Smith et al. 2017; Sullivan et al. 2019; Takeshita et al. 2017). Additionally, accidental releases may result in impacts on marine mammals due to effects on prey species (see Finfish, Invertebrates, and Essential Fish Habitat table).
Accidental releases: Trash and debris	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, lines and pipeline laying, and debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low quantity, local, and low-impact events. Worldwide 62 of 123 (50.4%) marine mammal species have been documented ingesting marine litter (Werner et al. 2016). Stranding data indicate potential debris induced mortality rates of 0 to 22%. Mortality has been documented in cases of debris interactions, as well as blockage of the digestive track, disease, injury, and malnutrition (Baulch and Perry 2014). However, it is difficult to link physiological effects to individuals to population level impacts (Browne et al. 2015).	As population and vessel traffic increase gradually over the next 40 years, accidental release of trash and debris may increase. Trash and debris may continue to be accidentally released through fisheries use and other offshore and onshore activities. There may also be a long-term risk from exposure to plastics and other debris in the ocean. Worldwide 62 of 123 (50.4%) of marine mammal species have been documented ingesting marine litter (Werner et al. 2016). Mortality has been documented in cases of debris interacts, as well as blockage of the digestive track, disease, injury, and malnutrition (Baulch and Perry 2014).
EMFs	EMFs emanate constantly from installed telecommunication and electrical power transmission cables. Marine mammals appear to have a detection threshold for magnetic intensity gradients (i.e., changes in magnetic field levels with distance) of 0.1% of the earth's magnetic field or about 0.05 μT (Kirschvink 1990) and are thus likely to be very sensitive to minor changes in magnetic fields (Walker et al. 2003). There is a potential for animals to react to local variations of the geomagnetic field caused by power cable EMFs. Depending on the magnitude and persistence of the confounding magnetic field, such an effect could cause a trivial temporary change in swim direction or a longer detour during the animal's migration (Gill et al. 2005). Such an effect on marine mammals is more likely to occur with direct current cables than with AC cables (Normandeau et al. 2011). However, there are numerous transmission cables installed across the seafloor and no impacts on marine mammals have been demonstrated from this source of EMF.	During operation, future new cables would produce EMF. Submarine power cables in the marine mammal geographic analysis area are assumed to be installed with appropriate shielding and burial depth to reduce potential EMF to low levels. EMF of any two sources would not overlap. Although the EMF would exist as long as a cable was in operation, impacts, if any, would likely be difficult to detect, if they occur at all. Marine mammals have the potential to react to submarine cable EMF; however, no effects from the numerous submarine cables have been observed. Furthermore, this IPF would be limited to extremely small portions of the areas used by migrating marine mammals. As such, exposure to this IPF would be low, and as a result impacts on marine mammals would not be expected.
Cable emplacement and maintenance	Cable maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances will be local and generally limited to the emplacement corridor. Data are not available regarding marine mammal avoidance of localized turbidity plumes; however, Todd et al. (Todd et al. 2015) suggest that since some marine mammals often live in turbid waters and some species of mysticetes and sirenians employ feeding methods that create sediment plumes, some species of marine mammals have a tolerance for increased turbidity. Similarly, McConnell et al. (McConnell et al. 1999) documented movements and foraging of grey seals in the North Sea. One tracked individual was blind in both eyes, but otherwise healthy. Despite being blind, observed movements were typical of the other study individuals, indicating that visual cues are not essential for grey seal foraging and movement (McConnell et al. 1999). If elevated turbidity caused any behavioral responses such as avoiding the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any impacts would be temporary and short term. Turbidity associated with increased sedimentation may result in temporary, short-term impacts on marine mammal prey species (see Finfish, Invertebrates, and Essential Fish Habitat table).	The impact on water quality from accidental sediment suspension during cable emplacement is temporary and short term. If elevated turbidity caused any behavioral responses such as avoidance of the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any negative impacts would be temporary and short term. Turbidity associated with increased sedimentation may result in temporary, short-term impacts on some marine mammal prey species (see Finfish, Invertebrates, and Essential Fish Habitat table).
Noise: Aircraft	Aircraft routinely travel in the marine mammal geographic analysis area. With the possible exception of rescue operations, no ongoing aircraft flights would occur at altitudes that would elicit a response from marine mammals. If flights are at a sufficiently low altitude, marine mammals may respond with behavioral changes, including short surface durations, abrupt dives, and percussive behaviors (i.e., breaching and tail slapping) (Patenaude et al. 2002). These brief responses would be expected to dissipate once the aircraft has left the area. Similarly, aircraft have the potential to disturb hauled-out seals if aircraft overflights occur within 2,000 feet (610 meters) of a haul out area (Efroymson et al. 2000).	Future low altitude aircraft activities such as survey activities and navy training operations could result short-term responses of marine mammals to aircraft noise. If flights are at a sufficiently low altitude, marine mammals may respond with a behavior changes, including short surface durations, abrupt dives, and percussive behaviors (i.e., breaching and tail slapping) (Patenaude et al. 2002). These brief responses would be expected to dissipate once the aircraft has left the area.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
	However, this disturbance would be temporary, short-term, and result in minimal energy expenditure. These brief responses would be expected to dissipate once the aircraft has left the area.	
Noise: G&G	Infrequent site characterization surveys and scientific surveys produce high-intensity impulsive noise around sites of investigation. These activities have the potential to result in high intensity, high consequence impacts, including auditory injuries, stress, disturbance, and behavioral responses, if present within the ensonified area (NOAA 2018). Survey protocols and underwater noise mitigation procedures are typically implemented to decrease the potential for any marine mammal to be within the area where sound levels are above relevant harassment thresholds associated with an operating sound source to reduce the potential for behavioral responses and injury (PTS/TTS) close to the sound source. The magnitude of effects, if any, is intrinsically related to many factors, including acoustic signal characteristics, behavioral state (e.g., migrating), biological condition, distance from the source, duration and level of the sound exposure, as well as environmental and physical conditions that affect acoustic propagation (NOAA 2018).	Same as ongoing activities, with the addition of possible future oil and gas exploration surveys.
Noise: Turbines	Marine mammals would be able to hear the continuous underwater noise of operational WTGs. As measured at the Block Island Wind Facility, this low frequency noise barely exceeds ambient levels at 164 feet (50 meters) from the WTG base. Based on the results of Thomsen et al. (Thomsen et al. 2015) and Kraus et al. (Kraus et al. 2016), SPLs would be expected to be at or below ambient levels at relatively short distances from the WTG foundations.	This sub-IPF does not apply to future non-offshore wind development.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can result in high-intensity, low-exposure level, long-term, but localized intermittent risk to marine mammals. Impacts would be localized in nearshore waters. Pile-driving activities may negatively affect marine mammals during foraging, orientation, migration, predator detection, social interactions, or other activities (Southall et al. 2007). Noise exposure associated with pile-driving activities can interfere with these functions and have the potential to cause a range of responses, including insignificant behavioral changes, avoidance of the ensonified area, PTS, harassment, and ear injury, depending on the intensity and duration of the exposure. BOEM assumes that all ongoing and potential future activities will be conducted in accordance with a project-specific IHA to minimize impacts on marine mammals.	No future activities were identified within the marine mammal geographic analysis area other than ongoing activities.
Noise: Cable laying/trenching	Noise from cable laying could periodically occur in the analysis area.	No future activities were identified within the marine mammal geographic analysis area other than ongoing activities.
Noise: Vessels	Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, scientific and academic research vessels, as well as other construction vessels. The frequency range for vessel noise falls within marine mammals' known range of hearing and would be audible. Noise from vessels presents a long-term and widespread impact on marine mammals across in most oceanic regions. While vessel noise may have some effect on marine mammal behavior, it would be expected to be limited to brief startle and temporary stress response. Results from studies on acoustic impacts from vessel noise on odontocetes indicate that small vessels at a speed of 5 knots in shallow coastal water can reduce the communication range for bottlenose dolphins within 164 feet (50 meters) of the vessel by 26% (Jensen et al. 2009). Pilot whales in a quieter, deep-water habitat could experience a 50% reduction in communication range from a similar size boat and speed (Jensen et al. 2009). Since lower frequencies propagate farther away from the sound source compared to higher frequencies, LFCs are at a greater risk of experiencing Level B Harassment produced by vessel traffic.	Any offshore projects that require the use of ocean vessels could potentially result in long term but infrequent impacts on marine mammals, including temporary startle responses, masking of biologically relevant sounds, physiological stress, and behavioral changes. However, BOEM expects that these brief responses of individuals to passing vessels would be unlikely given the patchy distribution of marine mammals and no stock or population level effects would be expected.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. Port expansion activities are localized to nearshore habitats, and are expected to result in temporary, short-term impacts, if any, on marine mammals. Vessel noise may affect marine mammals, but response would be expected to be temporary and short-term (see Vessels: Noise sub-IPF above). The impacts on water quality from sediment	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from South Carolina to Maine is that port activity will increase modestly. The ability of ports to receive the increase in larger ships will require port modifications. Future channel deepening activities are being undertaken to accommodate deeper draft vessels for the Panama Canal Locks. The additional traffic and larger vessels could have impacts on water quality through

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
	suspension during port expansion activities is temporary, short-term, and would be similar to those described under the cable emplacement and maintenance IPF above.	increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long-term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g. ferry use and cruise industry) and may continue to increase in the foreseeable future. Additional impacts associated with the increased risk of vessel strike could also occur (see the Traffic: Vessel collisions sub-IPF below).
Presence of structures: Entanglement or ingestion of lost fishing gear	There are more than 130 artificial reefs in the Mid-Atlantic region. This sub-IPF may result in long-term, high intensity impacts, but with low exposure due to localized and geographic spacing of artificial reefs, long-term. Currently bridge foundations and the Block Island Wind Facility may be considered artificial reefs and may have higher levels of recreational fishing, which increases the chances of marine mammals encountering lost fishing gear, resulting in possible ingestions, entanglement, injury, or death of individuals (Moore and van der Hoop 2012), if present nearshore where these structures are located. There are very few, if any, areas within the OCS geographic analysis area for marine mammals that would serve to concentrate recreational fishing and increase the likelihood that marine mammals would encounter lost fishing gear.	No future activities were identified within the marine mammal geographic analysis area other than ongoing activities.
Presence of structures: Habitat conversion and prey aggregation	There are more than 130 artificial reefs in the Mid-Atlantic region. Hard-bottom (scour control and rock mattresses) and vertical structures (bridge foundations and Block Inland Wind Facility WTGs) in a soft-bottom habitat can create artificial reefs, thus inducing the “reef” effect (Taormina et al. 2018; NMFS 2015). The reef effect is usually considered a beneficial impact, associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for seals and small odontocetes compared to the surrounding soft-bottoms.	The presence of structures associated with non-offshore wind development in near shore coastal waters have the potential to provide habitat for seals and small odontocetes as well as preferred prey species. This “reef effect” has the potential to result in long term, low-intensity benefits. Bridge foundations will continue to provide foraging opportunities for seals and small odontocetes with measurable benefits to some individuals. Hard-bottom (scour control and rock mattresses used to bury the offshore export cables) and vertical structures (i.e., WTG and OSP foundations) in a soft-bottom habitat can create artificial reefs, thus inducing the “reef effect” (Taormina et al. 2018; Causon and Gill 2018). The reef effect is usually considered a beneficial impact, associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for marine mammals compared to the surrounding soft-bottoms.
Presence of structures: Avoidance/displacement	No ongoing activities in the marine mammal geographic analysis area beyond offshore wind facilities are measurably contributing to this sub-IPF. There may be some impacts resulting from the existing Block Island Wind Facility, but given that there are only 5 WTGs, no measurable impacts are occurring.	Not contemplated for non-offshore wind facility sources.
Presence of structures: Behavioral disruption - breeding and migration	No ongoing activities in the marine mammal geographic analysis area beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore wind facility sources.
Presence of structures: Displacement into higher risk areas (Vessels and Fishing)	No ongoing activities in the marine mammal geographic analysis area beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore wind facility sources.
Traffic: Vessel collisions	Current activities that are contributing to this sub-IPF include port traffic levels, fairways, TSS, commercial vessel traffic, recreational and fishing activity, and scientific and academic vessel traffic. Vessel strike is relatively common with cetaceans (Kraus et al. 2005) and one of the primary causes of death to NARWs with as many as 75% of known anthropogenic mortalities of NARWs likely resulting from collisions with large ships along the U.S. and Canadian eastern seaboard (Kite-Powell et al. 2007). Marine mammals are more vulnerable to vessel strike when they are within the draft of the vessel and when they are beneath the surface and not detectable by visual observers. Some conditions that make marine mammals less detectable include weather conditions with poor visibility (e.g., fog, rain, and wave height) or nighttime operations. Vessels operating at speeds exceeding 10 knots have been associated with the highest risk for vessel strikes of NARWs (Vanderlaan and Taggart 2007). Reported vessel collisions with whales show that serious injury rarely occurs at speeds below 10 knots (Laist et al. 2001). Data show that the probability of a vessel strike increases with the velocity of a vessel (Pace and Silber 2005; Vanderlaan and Taggart 2007).	Vessel traffic associated with non-offshore wind development has the potential to result in an increased collision risk. While these impacts would be high consequence, the patchy distribution of marine mammals makes stock or population-level effects unlikely (Navy 2018).

µT = microtesla; AC = alternating current; EMF = electromagnetic field; hazmat = hazardous materials; IHA = Incidental Harassment Authorization; NARW = North Atlantic right whale; PTS = permanent threshold shift; SPLs = sound pressure levels; TSS = total suspended solids; TTS = temporary threshold shift

Table D1-13. Summary of activities and the associated impact-producing factors for navigation and vessel traffic

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Anchoring	Larger commercial vessels (specifically tankers) sometimes anchor outside of major ports to transfer their cargo to smaller vessels for transport into port, an operation known as lightering. These anchors have deeper ground penetration and are under higher stresses. Smaller vessels (commercial fishing or recreational vessels) would anchor for fishing and other recreational activities. These activities cause temporary to short-term impacts on navigation in the immediate anchorage area. All vessels may anchor in an emergency scenario (such as power loss) if they lose power to prevent them from drifting and creating navigational hazards for other vessels or drifting into structures.	Lightering and anchoring operations are expected to continue at or near current levels, with the expectation of moderate increase commensurate with any increase in tankers visiting ports. Deep draft visits to major port visits are expected to increase as well, increasing the potential for an emergency need to anchor, creating navigational hazards for other vessels. Recreational activity and commercial fishing activity would likely stay largely the same related to this IPF.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. Impacts from these activities would be short term and could include congestion in ports, delays, and changes in port usage by some fishing or recreational vessel operators.	Ports would need to perform maintenance and perform upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep draft vessels as they continue to increase in size. Impacts would be short term and could include congestion in ports, delays, and changes in port usage by some fishing or recreational vessel operators.
Presence of structures: Allisions	An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. There are two types of allisions that occur: drift and powered. A drift allision generally occurs when a vessel is powered down due to operator choice or power failure. A powered allision generally occurs when an operator fails to adequately control their vessel movements or is distracted.	Although there are some exceptions (ferry traffic and cruise ships), BOEM expects vessel traffic to remain relatively steady into the reasonably foreseeable future (BOEM 2019:57). Vessel allisions with non-offshore wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.
Presence of structures: Fish aggregation	Items in the water, such as ghost fishing gear, buoys, and energy platform foundations can create an artificial reef effect, aggregating fish. Recreational and commercial fishing can occur near the artificial reefs. Recreational fishing is more popular than commercial near artificial reefs as commercial mobile fishing gear can risk snagging on the artificial reef structure.	Fishing near artificial reefs is not expected to change meaningfully over the next 40 years.
Presence of structures: Habitat conversion	Equipment in the ocean can create a substrate for mollusks to attach to, and fish eggs to settle near. This can create a reef-like habitat and benefit structure-oriented species on a constant basis.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Migration disturbances	Noise-producing activities, such as pile driving and vessel traffic, may interfere and adversely affect marine mammals during foraging, orientation, migration, response to predators, social interactions, or other activities. Marine mammals may also be sensitive to changes in magnetic field levels. The presence of structures and operational noise could cause mammals to avoid areas.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions. When multiple vessels need to navigate around a structure, then navigation is made more complex, as the vessels need to avoid both the structure and each other.	Although there are some exceptions (ferry traffic and cruise ships), BOEM expects vessel traffic to remain relatively steady into the reasonably foreseeable future (BOEM 2019:57). Even with increased port visits by deep-draft vessels, this is still a relatively small effect when considering the whole of Atlantic Coast vessel traffic. The presence of navigation hazards is expected to continue at or near current levels.
Presence of structures: Space use conflicts	Currently, the offshore area is occupied by marine trade, stationary and mobile fishing, and survey activities.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Cable infrastructure	See IPF for Anchoring.	See IPF for Anchoring.
Cable emplacement and maintenance	Within the geographic analysis area for navigation and vessel traffic, existing cables may require access for maintenance activities. Infrequent cable maintenance activities may cause temporary increases in vessel traffic and navigational complexity.	Future new cables would cause temporary increases in vessel traffic during installation or maintenance, resulting in infrequent, localized, short-term impacts over the next 40 years. Care would need to be taken by vessels that are crossing the cable routes during these activities.
Traffic: Aircraft	USCG SAR helicopters are the main aircraft that may be flying at low enough heights to risk interaction with WTGs. USCG SAR aircraft need to fly low enough that they can spot objects in the water.	SAR operations could be expected to increase with any increase in vessel traffic. However, as vessel traffic volume is not expected to increase appreciably, neither should SAR operations. EIS Section 3.6.6 provides a discussion of navigation impacts on fishing vessel traffic.
Traffic: Vessels	See the sub-IPF for Presence of structures: Navigation hazard.	See the sub-IPF for Presence of structures: Navigation hazard.
Traffic: Vessels, collisions	See the sub-IPF for Presence of structures: Navigation hazard.	See the sub-IPF for Presence of structures: Navigation hazard.

SAR = Search and Rescue

Table D1-14. Summary of activities and the associated impact-producing factors for other uses: military and national security uses

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Allisions	Existing stationary facilities that present allision risks include buoys that are used to mark inlet approaches, channels, and shoals, dock facilities, meteorological buoys associated with offshore wind lease areas, and other offshore or shoreline-based structures.	No additional non-offshore wind stationary structures were identified within the geographic analysis area. Stationary structures such as private or commercial docks may be added close to the shoreline.
Presence of structures: Fish aggregation	No existing stationary structures that would act as FADs were identified within the geographic analysis area.	No future non-offshore wind additional stationary structures that would act as FADs were identified within the geographic analysis area.
Presence of structures: Navigation hazard	Existing stationary facilities within the geographic analysis area that present navigational hazards include buoys that are used to mark inlet approaches, channels, and shoals, dock facilities, meteorological buoys associated with offshore wind lease areas, and other offshore or shoreline-based structures.	No future non-offshore wind stationary structures were identified within the offshore analysis area. Onshore, development activities are anticipated to continue with additional proposed communications towers and onshore commercial, industrial, and residential developments.
Presence of structures: Space use conflicts	Existing stationary facilities within the geographic analysis area that could present a space use conflict include onshore wind turbines, communication towers, and other onshore commercial, industrial, and residential structures.	No future non-offshore wind stationary structures were identified within the offshore analysis area. Onshore, development activities are anticipated to continue with additional proposed communications towers and onshore commercial, industrial, and residential developments.
Presence of structures: Cable infrastructure	Existing submarine cables cross cumulative lease areas.	Submarine cables would remain in current locations with infrequent maintenance continuing along those cable routes for the foreseeable future.
Traffic: Vessels	Current vessel traffic in the region is described in EIS Section 3.6.6. Vessel activities associated with offshore wind in the cumulative lease areas is currently limited to site assessment surveys.	Continued vessel traffic in the region.
Traffic: Vessels, collisions	Current vessel traffic in the region is described in EIS Section 3.6.6. Vessel activities associated with offshore wind in the cumulative lease areas is currently limited to site assessment surveys.	Continued vessel traffic in the region.

FAD = fish aggregating device; SAR =

Table D1-15. Summary of activities and the associated impact-producing factors for other uses: aviation and air traffic

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Towers	Existing aboveground stationary facilities within the geographic analysis area that present aviation hazards include onshore wind turbines, communication towers, dock facilities, and other onshore structures exceeding 200 feet in height.	No future non-offshore wind stationary structures were identified within the offshore analysis area. Onshore development activities are anticipated to continue with additional proposed communications towers.
Presence of structures: Space use conflicts	Existing aboveground stationary facilities within the geographic analysis area that could cause space use conflicts for aircraft include onshore wind turbines, communication towers, and other onshore structures exceeding 200 feet in height.	No future non-offshore wind stationary structures were identified within the offshore analysis area. Onshore, development activities are anticipated to continue with additional proposed communications towers.

Table D1-16. Summary of activities and the associated impact-producing factors for other uses: cables and pipelines

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Allisions and navigation hazards	Structures within and near the geographic analysis area that pose potential allision hazards include buoys that are used to mark inlet approaches, channels, and shoals, meteorological buoys associated with offshore wind lease areas, and shoreline developments such as docks, ports, and other commercial, industrial, and residential structures.	Reasonably foreseeable non-offshore wind structures that could affect submarine cables have not been identified in the geographic analysis area.
Presence of structures: Space use conflicts	Existing submarine cables cross cumulative lease areas and create potential space use conflicts with marine mineral and sand borrow areas.	Reasonably foreseeable non-offshore wind structures that could create space use conflicts with submarine cables have not been identified in the geographic analysis area.
Presence of structures: Cable infrastructure	Existing submarine cables cross cumulative lease areas.	Reasonably foreseeable non-offshore wind structures have not been identified in the geographic analysis area.

Table D1-17. Summary of activities and the associated impact-producing factors for other uses: radar systems

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent

Presence of structures: Towers	Wind developments in the direct line-of-sight with, or extremely close to, radar systems can cause clutter and interference.	Reasonably foreseeable non-offshore wind structures proposed for construction in the lease areas that could affect radar systems have not been identified.

Table D1-18. Summary of activities and the associated impact-producing factors for other uses: scientific research and surveys

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Presence of structures: Navigation hazards	Stationary structures are limited in the open ocean environment of the geographic analysis area, and include met buoys associated with site assessment activities, the five Block Island Wind Farm WTGs, and the two Coastal Virginia Offshore Wind WTGs.	Reasonably foreseeable non-offshore wind activities would not implement stationary structures within the open ocean environment that would pose navigational hazards and raise the risk of allisions for survey vessels and collisions for survey aircraft.

met = meteorological

Table D1-19. Summary of activities and the associated impact-producing factors for recreation and tourism

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Anchoring	Anchoring occurs due to ongoing military, survey, commercial, and recreational activities.	Impacts from anchoring would continue, and may increase due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. Modest growth in vessel traffic could increase the temporary, localized impacts of navigational hazards, increased turbidity levels, and potential for direct contact causing mortality of benthic resources.
Light: Vessels	Ocean vessels have an array of lights including navigational lights and deck lights.	Anticipated modest growth in vessel traffic would result in some growth in the nighttime traffic of vessels with lighting.
Light: Structures	Offshore buoys and towers emit low-intensity light. Onshore structures, including houses and ports, emit substantially more light on an ongoing basis.	Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore.
Cable emplacement and maintenance	Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances would be local and limited to emplacement corridors.	Cable maintenance or replacement of existing cables in the geographic analysis area would occur infrequently and would generate short-term disturbances.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. These disturbances are temporary, local, and extend only a short distance beyond the work area.	No future activities were identified within the recreation and tourism geographic analysis area other than ongoing activities.
Noise: Cable laying/trenching	Offshore trenching occurs periodically in connection with cable installation or sand and gravel mining.	No future activities were identified within the recreation and tourism geographic analysis area other than ongoing activities.
Noise: Vessels	Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels.	Planned new barge routes and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance.	Ports would need to perform maintenance and upgrade facilities over the next 40 years to ensure that they can still receive the projected future volume of vessels visiting their ports, and to be able to host larger deep-draft vessels as they continue to increase in size.
Port utilization: Maintenance/dredging	Periodic maintenance is necessary for harbors within the analysis area.	Ongoing maintenance and dredging of harbors within the geographic analysis area will continue as needed. No specific projects are known.
Presence of structures: Allisions	An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. The likelihood of allisions is expected to continue at or near current levels.	Vessel allisions with non-offshore wind stationary objects should not increase meaningfully without a substantial increase in vessel congestion.
Presence of structures: Entanglement, gear loss, gear damage	Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures.	No future activities were identified within the recreation and tourism geographic analysis area other than ongoing activities.
Presence of structures: Fish aggregation	Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these locations. Recreational and commercial fishing can occur near these aggregation	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
	locations, although recreational fishing is more popular, because commercial mobile fishing gear is more likely to snag on structures.	
Presence of structures: Habitat conversion	Structures, including foundations, scour protection around foundations, and various means of hard protection atop cables create uncommon relief in a mostly flat seascape. Structure-oriented species thus benefit on a constant basis.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Navigation hazard	Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure, because vessels need to avoid both the structure and each other.	Vessel traffic, overall, is not expected to meaningfully increase over the next 40 years. The presence of navigation hazards is expected to continue at or near current levels.
Presence of structures: Space use conflicts	Current structures do not result in space use conflicts.	Reasonably foreseeable activities (non-offshore wind) would not result in additional offshore structures.
Presence of structures: Viewshed	The only existing offshore structures within the viewshed of the Project are minor features such as buoys.	Non-offshore wind structures that could be viewed in conjunction with the offshore components of the Project would be limited to meteorological towers. Marine activity would also occur within the marine viewshed.
Traffic: Vessels	Geographic analysis area ports and marine traffic related to shipping, fishing, and recreation are important to the region's economy. No substantial changes are anticipated to existing vessel traffic volumes.	New vessel traffic near the geographic analysis area would be generated by proposed barge routes and dredging demolition sites over the next 40 years. Marine commerce and related industries would continue to be important to the geographic analysis area economy.
Traffic: Vessel collisions	The region's substantial marine traffic may result in occasional vessel collisions, which would result in costs to the vessels involved. The likelihood of collisions is expected to continue at or near current rates.	An increased risk of collisions is not anticipated from future activities.

Table D1-20. Summary of activities and the associated impact-producing factors for sea turtles

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	See the Water Quality table for a quantitative analysis of these risks. Ongoing releases are frequent and chronic. Sea turtle exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality (Shigenaka et al. 2010) or sublethal effects on individual fitness, including adrenal effects, dehydration, hematological effects, increased disease incidence, liver effects, poor body condition, skin effects, skeletomuscular effects, and several other health effects that can be attributed to oil exposure (Camacho et al. 2013; Bembenek-Bailey et al. 2019; Mitchelmore et al. 2017; Shigenaka et al. 2010; Vargo et al. 1986). Additionally, accidental releases may result in impacts on sea turtles due to effects on prey species (see Finfish, Invertebrates, and Essential Fish Habitat table).	Gradually increasing vessel traffic over the next 40 years would increase the risk of accidental releases. Sea turtle exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality (Shigenaka et al. 2010; Wallace et al. 2010) or sublethal effects on individual fitness, including adrenal effects, dehydration, hematological effects, increased disease incidence, liver effects, poor body condition, skin effects, skeletomuscular effects, and several other health effects that can be attributed to oil exposure (Camacho et al. 2013; Bembenek-Bailey et al. 2019; Mitchelmore et al. 2017; Shigenaka et al. 2010; Vargo et al. 1986). Additionally, accidental releases may result in impacts on sea turtles due to effects on prey species (see Finfish, Invertebrates, and Essential Fish Habitat table).
Accidental releases: Trash and debris	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities, cables, lines, and pipeline laying, as well as debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low quantity, local, and low-impact events. Direct ingestion of plastic fragments is well documented and has been observed in all species of sea turtles (Bugoni et al. 2001; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014). In addition to plastic debris, ingestion of tar, paper, Styrofoam™, wood, reed, feathers, hooks, lines, and net fragments have also been documented (Thomás et al. 2002). Ingestion can also occur when individuals mistake debris for potential prey items (Gregory 2009; Hoarau et al. 2014; Thomás et al. 2002). Potential ingestion of marine debris varies among species and life history stages due to differing feeding strategies (Nelms et al. 2016). Ingestion of plastics and other marine debris can result in both lethal and sublethal impacts on sea turtles, with sublethal effects more difficult to detect (Gall and Thompson 2015; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014). Long-term sublethal effects may include dietary dilution, chemical contamination, depressed immune system function, poor body condition, as well as reduced growth rates, fecundity, and reproductive success. However, these effects are cryptic and clear causal links are difficult to identify (Nelms et al. 2016).	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, lines and pipeline laying, and debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low quantity, local, and low-impact events. Direct and indirect ingestion of plastic fragments and other marine debris is well documented and has been observed in all species of sea turtles (Bugoni et al. 2001; Gregory 2009; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014; Thomás et al. 2002). Ingestion can result in both lethal and sublethal impacts on sea turtles, with sublethal effects more difficult to detect (Gall and Thompson 2015; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014). However, these effects are cryptic and clear causal links are difficult to identify (Nelms et al. 2016).
EMFs	EMFs emanate constantly from installed telecommunication and electrical power transmission cables. Sea turtles appear to have a detection threshold of magnetosensitivity and behavioral responses to field intensities ranging	During operations, future new cables would produce EMF. Submarine power cables in the geographic analysis area for sea turtles are assumed to be installed with appropriate shielding and burial depth to reduce potential

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
	from 0.0047 to 4000 µT for loggerhead turtles, and 29.3 to 200 µT for green turtles, with other species likely similar due to anatomical, behavioral, and life history similarities (Normandeau et al. 2011). Juvenile or adult sea turtles foraging on benthic organisms may be able to detect magnetic fields while they are foraging on the bottom near the cables and up to potentially 82 feet (25 meters) in the water column above the cable. Juvenile and adult sea turtles may detect the EMF over relatively small areas near cables (e.g., when resting on the bottom or foraging on benthic organisms near cables or concrete mattresses). There are no data on impacts on sea turtles from EMFs generated by underwater cables, although anthropogenic magnetic fields can influence migratory deviations (Luschi et al. 2007; Snoek et al. 2016). However, any potential impacts from AC cables on turtle navigation or orientation would likely be undetectable under natural conditions, and thus would be insignificant (Normandeau et al. 2011).	EMF to low levels. (Section 5.2.7 of BOEM's 2007 Final Programmatic EIS for Alternative Energy Development and Production and Alternate Use of Facilities on the Outer Continental Shelf.) EMF of any two sources would not overlap. Although the EMF would exist as long as a cable was in operation, impacts, if any, would likely be difficult to detect, if they occur at all. Furthermore, this IPF would be limited to extremely small portions of the areas used by resident or migrating sea turtles. As such, exposure to this IPF would be low, and as a result, impacts on sea turtles would not be expected.
Light: Vessels	Ocean vessels such as ongoing commercial vessel traffic, recreational and fishing activity, scientific and academic research traffic have an array of lights including navigational, deck lights, and interior lights. Such lights have some limited potential to attract sea turtles, although the impacts, if any, are expected to be localized and temporary.	Construction, operations, and decommissioning vessels associated with non-offshore wind activities produce temporary and localized light sources that could result in the attraction or avoidance behavior of sea turtles. These short-term impacts are expected to be of low intensity and occur infrequently.
Light: Structures	Artificial lighting on nesting beaches or in nearshore habitats has the potential to result in disorientation to nesting females and hatchling turtles. Artificial lighting on the OCS does not appear to have the same potential for effects. Decades of oil and gas platform operation in the Gulf of Mexico, that can have considerably more lighting than offshore WTGs, has not resulted in any known impacts on sea turtles (BOEM 2019).	Non-offshore wind activities would not be expected to appreciably contribute to this sub-IPF. As such, no impact on sea turtles would be expected.
Cable emplacement and maintenance	Cable maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances will be local and generally limited to the emplacement corridor. Data are not available regarding effects of suspended sediments on adult and juvenile sea turtles, although elevated suspended sediments may cause individuals to alter normal movements and behaviors. However, these changes are expected to be too small to be detected (NOAA 2020). Sea turtles would be expected to swim away from the sediment plume. Elevated turbidity is most likely to affect sea turtles if a plume causes a barrier to normal behaviors, but no impacts would be expected due to swimming through the plume (NOAA 2020). Turbidity associated with increased sedimentation may result in short-term, temporary impacts on sea turtle prey species (see Finfish, Invertebrates, and Essential Fish Habitat table).	The impact on water quality from accidental sediment suspension during cable emplacement is short-term and temporary. If elevated turbidity caused any behavioral responses such as avoidance of the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any impacts would be short-term and temporary. Turbidity associated with increased sedimentation may result in short-term, temporary impacts on some sea turtle prey species (see Finfish, Invertebrates, and Essential Fish Habitat table).
Noise: Aircraft	Aircraft routinely travel in the geographic analysis area for sea turtles. With the possible exception of rescue operations, no ongoing aircraft flights would occur at altitudes that would elicit a response from sea turtles. If flights are at a sufficiently low altitude, sea turtles may respond with a startle response (diving or swimming away), altered submergence patterns, and a temporary stress response (NSF and USGS 2011; Samuel et al. 2005). These brief responses would be expected to dissipate once the aircraft has left the area.	Future low-altitude aircraft activities such as survey activities and navy training operations could result in short-term responses of sea turtles to aircraft noise. If flights are at a sufficiently low altitude, sea turtles may respond with a startle response (diving or swimming away), altered submergence patterns, and a temporary stress response (NSF and USGS 2011; Samuel et al. 2005). These brief responses would be expected to dissipate once the aircraft has left the area.
Noise: G&G	Infrequent site characterization surveys and scientific surveys produce high-intensity impulsive noise around sites of investigation. These activities have the potential to result in some impacts including potential auditory injuries, short-term disturbance, behavioral responses, and short-term displacement of feeding or migrating sea turtles, if present within the ensonified area (NSF and USGS 2011). The potential for PTS and TTS is considered possible in proximity to G&G surveys utilizing air guns, but impacts are unlikely as turtles would be expected to avoid such exposure and survey vessels would pass quickly (NSF and USGS 2011). No significant impacts would be expected at the population level.	Same as ongoing activities, with the addition of possible future oil and gas exploration surveys.
Noise: Turbines	Available evidence suggests that typical underwater noise levels from operating WTGs would be below current cumulative injury and behavioral effect thresholds for sea turtles. Operating turbines were determined to produce underwater noise on the order of 110 to 125 dB_{RMS}, occasionally reaching as high as 128 dB_{RMS}, in the 10-Hz to 8-kilohertz range (Tougaard et al. 2020). As measured at the Block Island Wind Facility, low frequency operational noise barely exceeds ambient levels at 164 feet (50 meters) from the WTG base (Miller and Potty 2017). Operational noise impacts would be expected to be negligible.	This sub-IPF does not apply to future non-offshore wind development.
Noise: Pile driving	Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seabed can result in high intensity, low exposure levels, and long-term, but localized intermittent risk to sea turtles. Impacts, potentially including behavioral responses, masking, TTS, and PTS, would be localized in nearshore waters. Data regarding threshold levels for	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
	impacts on sea turtles from sound exposure during pile driving are very limited, and no regulatory threshold criteria have been established for sea turtles. Based on current literature, the following thresholds are used to assess impacts on turtles: Potential mortal injury: 210 dB cumulative SPL or greater than 207 dB peak SPL (Popper et al. 2014) Potential mortal injury: 204 dB_{SEL}, 232 dB_{PEAK} (PTS), 189 dB_{SEL}, 226 dB_{PEAK} (TTS) (Navy 2017) Behavioral harassment: 175 dB referenced to 1 µPa RMS (Navy 2017)	
Noise: Vessels	The frequency range for vessel noise (10 to 1000 Hz; MMS 2007) overlaps with sea turtles' known hearing range (less than 1,000 Hz with maximum sensitivity between 200 to 700 Hz; Bartol 1994) and would therefore be audible. However, Hazel et al. (Hazel et al. 2007) suggests that sea turtles' ability to detect approaching vessels is primarily vision-dependent, not acoustic. Sea turtles may respond to vessel approach and/or noise with a startle response (diving or swimming away) and a temporary stress response (NSF and USGS 2011). Samuel et al. (Samuel et al. 2005) indicated that vessel noise could have an effect on sea turtle behavior, especially their submergence patterns.	Any offshore projects that require the use of ocean vessels could potentially result in long-term but infrequent impacts on sea turtles, including temporary startle responses, masking of biologically relevant sounds, physiological stress, and behavioral changes, especially their submergence patterns (NSF and USGS 2011; Samuel et al. 2005). However, BOEM expects that these brief responses of individuals to passing vessels would be unlikely given the patchy distribution of sea turtles and no stock or population level effects would be expected.
Port utilization: Expansion	The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. Port expansion activities are localized to nearshore habitats, and are expected to result in short-term, temporary impacts, if any, on sea turtles. Vessel noise may affect sea turtles, but response would be expected to be short-term and temporary (see the Vessels: Noise sub-IPF above). The impact on water quality from sediment suspension during port expansion activities is short-term, temporary, and would be similar to those described under the cable emplacement and maintenance IPF above.	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from South Carolina to Maine is that port activity will increase modestly. The ability of ports to receive the increase in larger ships will require port modifications. Future channel deepening activities are being undertaken to accommodate deeper draft vessels for the Panama Canal Locks. The additional traffic and larger vessels could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long-term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and may continue to increase in the foreseeable future. Additional impacts associated with the increased risk of vessel strikes could also occur (see the Traffic: Vessel collisions sub-IPF below).
Presence of structures: Entanglement or ingestion of lost fishing gear	The Mid-Atlantic region has more than 130 artificial reefs. Currently bridge foundations and the Block Island Wind Facility may be considered artificial reefs and may have higher levels of recreational fishing, which increases the chances of sea turtles encountering lost fishing gear, resulting in possible ingestions, entanglement, injury, or death of individuals (Berreiros and Raykov 2014; Gregory 2009; Vegter et al. 2014) if present where these structures are located. At the scale of the OCS geographic analysis area for sea turtles, there are very few areas that would serve to concentrate recreational fishing and increase the likelihood that sea turtles would encounter lost fishing gear.	No future activities were identified within the geographic analysis area for sea turtles other than ongoing activities.
Presence of structures: Habitat conversion and prey aggregation	The Mid-Atlantic region has more than 130 artificial reefs. Hard-bottom (scour control and rock mattresses) and vertical structures (bridge foundations, Block Island Wind Facility WTGs, and two WTGs with the Coastal Virginia Offshore Wind pilot project) in a soft-bottom habitat can create artificial reefs, thus inducing the reef effect (Taormina et al. 2018; NMFS 2015). The reef effect is usually considered a beneficial impact, associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for sea turtles compared to the surrounding soft-bottoms.	The presence of structures associated with non-offshore wind development in near-shore coastal waters has the potential to provide habitat for sea turtles as well as preferred prey species. This reef effect has the potential to result in long-term, low-intensity beneficial impacts. Bridge foundations will continue to provide foraging opportunities for sea turtles with measurable benefits to some individuals.
Presence of structures: Avoidance/displacement	No ongoing activities in the geographic analysis area for sea turtles beyond offshore wind facilities are measurably contributing to this sub-IPF. There may be some impacts resulting from the existing Block Island Wind Facility (5 WTGs) and the Coastal Virginia Offshore Wind pilot project (2 WTGs) but given the limited number of WTGs, no measurable impacts are occurring.	Not contemplated for non-offshore wind facility sources.
Presence of structures: Behavioral disruption - breeding and migration	No ongoing activities in the geographic analysis area for sea turtles beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore wind facility sources.
Presence of structures: Displacement into higher risk areas (Vessels and Fishing)	No ongoing activities in the geographic analysis area for sea turtles beyond offshore wind facilities are measurably contributing to this sub-IPF.	Not contemplated for non-offshore wind facility sources.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Traffic: Vessel collisions	Current activities contributing to this sub-IPF include port traffic levels, fairways, TSS, commercial vessel traffic, recreational and fishing activity, and scientific and academic vessel traffic. Propeller and collision injuries from boats and ships are common in sea turtles. Vessel strike is an increasing concern for sea turtles, especially in the southeastern United States, where development along the coasts is likely to result in increased recreational boat traffic. Sea turtles are most susceptible to vessel collisions in coastal waters, where they forage from May through November. Vessel speed may exceed 10 knots in such waters, and evidence suggests that they cannot reliably avoid being struck by vessels exceeding 2 knots (Hazel et al. 2007).	Vessel traffic associated with non-offshore wind development has the potential to result in an increased collision risk. While these impacts would be high consequence, the patchy distribution of sea turtles makes stock or population-level effects unlikely (Navy 2018).

µPa = micropascal; µT = microtesla; AC = alternating current; dB = decibels; hazmat = hazardous materials; HZ = hertz; PTS = permanent threshold shift; RMS = root mean square; SPL = sound pressure level; TTS = temporary threshold shift

Table D1-21. Summary of activities and the associated impact-producing factors for water quality

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat	Accidental releases of fuels and fluids occur during vessel usage for dredge material ocean disposal, fisheries use, marine transportation, military use, survey activities, and submarine cable lines, and pipeline laying activities. According to the DOE, 31,000 barrels of petroleum are spilled into U.S. waters from vessels and pipelines in a typical year. Approximately 40.5 million barrels of oil were lost as a result of tanker incidents from 1970 to 2009, according to International Tanker Owners Pollution Federation Limited, which collects data on oil spills from tankers and other sources. From 1990 to 1999, the average annual input to the coastal Northeast was 220,000 barrels of petroleum and into the offshore was < 70,000 barrels. Impacts on water quality would be expected to brief and localized from accidental releases.	Future accidental releases from offshore vessel usage, spills, and consumption will likely continue on a similar trend. Impacts are unlikely to affect water quality.
Accidental releases: Trash and debris	Trash and debris may be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities, and cables, lines, and pipeline laying. Accidental releases of trash and debris are expected to be low probability events. BOEM assumes operator compliance with federal and international requirements for management of shipboard trash; such events also have a relatively limited spatial impact.	As population and vessel traffic increase gradually over the next 40 years, accidental release of trash and debris may increase. However, there does not appear to be evidence that the volumes and extents anticipated would have any effect on water quality.
Anchoring	Impacts from anchoring occur due to ongoing military use and survey, commercial, and recreational activities.	Impacts from anchoring may occur semi-regularly over the next 40 years due to offshore military operations or survey activities. These impacts would include increased seabed disturbance resulting in increased turbidity levels. All impacts would be localized, short term, and temporary.
Cable emplacement and maintenance	Elevated suspended sediment concentrations can occur under natural tidal conditions and increase during storms, trawling, and vessel propulsion. Survey activities, and new cable and pipeline laying activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances would be short-term and either be limited to the emplacement corridor or localized.	Suspension of sediments may continue to occur infrequently over the next 40 years due to survey activities, and submarine cable, lines, and pipeline-laying activities. Future new cables would occasionally disturb the seafloor and cause short-term increases in turbidity and minor alterations in localized currents resulting in local short-term impacts. If the cable routes enter the water quality geographic analysis area, short-term disturbance in the form of increased suspended sediment and turbidity would be expected.
Port utilization: Expansion	Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from South Carolina to Maine is that port activity will increase modestly. The ability of ports to receive the increase in larger ships will require port modifications, which, along with additional vessel traffic, could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long-term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and may continue to increase in the foreseeable future.	The general trend along the coastal region from South Carolina to Maine is that port activity will increase modestly over the next 40 years. Port modifications and channel deepening activities are being undertaken to accommodate the increase in vessel traffic and deeper draft vessels that transit the Panama Canal Locks. The additional traffic and larger vessels could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and may continue to increase in the foreseeable future.
Presence of structures	The installation of onshore and offshore structures leads to alteration of local water currents. These disturbances would be local but, depending on the hydrologic conditions, have the potential to impact water quality through the formation of sediment plumes.	Impacts associated with the presence of structures includes temporary sediment disturbance during maintenance. This sediment suspension would lead to interim and localized impacts.
Discharges/intakes	Discharges impact water quality by introducing nutrients, chemicals, and sediments to the water. There are regulatory requirements related to prevention and control of discharges, the prevention and control of accidental spills, and the prevention and control of nonindigenous species.	Increased coastal development is causing increased nutrient pollution in communities. In addition, ocean disposal activity in the North and Mid-Atlantic is expected to gradually decrease or remain stable. Impacts of ocean disposal on water quality are minimized because USEPA has established dredge spoil criteria and regulate the disposal permits issued by USACE.

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
		The impact on water quality from sediment suspension during these future activities would be short-term and localized.
Land disturbance: erosion and sedimentation	Ground disturbance activities may lead to un-vegetated or otherwise unstable soils. Precipitation events could potentially mobilize the soils into nearby surface waters, leading to potential erosion and sedimentation effects and subsequent increased turbidity.	Ground disturbance associated with construction and installation of onshore components could lead to un-vegetated or unstable soils. Precipitation events could mobilize these soils leading to erosion and sedimentation effects and turbidity. The impacts for future offshore wind through this IPF would be staggered in time and localized. The impacts would be short term and localized with an increased likelihood of impacts limited to onshore construction periods.
Land disturbance: Onshore construction	Onshore construction activities may lead to un-vegetated or otherwise unstable soils as well as soil contamination due to leaks or spills from construction equipment. Precipitation events could potentially mobilize the soils into nearby surface waters, leading to increased turbidity and alteration of water quality.	The general trend along coastal regions is that port activity will increase modestly in the future. This increase in activity includes expansion needed to meet commercial, industrial, and recreational demand. Modifications to cargo handling equipment and conversion of some undeveloped land to meet port demand would be required to receive the increase in larger ships.

DOE = U.S. Department of Energy; hazmat = hazardous materials

Table D1-22. Summary of activities and the associated impact-producing factors for scenic and visual resources

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Accidental releases: Fuel/fluids/hazmat, suspended sediments, trash and debris	Ongoing offshore and onshore construction projects involve the use of vehicles, vessels, and equipment that contain fuel, fluids, and hazmat that have the potential for accidental release. Offshore and onshore construction can also result in sedimentation from land and seabed disturbance and accidental releases of trash and debris with associated visual impacts.	Future offshore and onshore construction projects have the potential to result in accidental releases from vehicles, vessels, and equipment that contain fuel, fluids, and hazmat. Future offshore and onshore construction could also result in sedimentation from land and seabed disturbance and accidental releases of trash and debris with associated visual impacts.
Land disturbance: Erosion and sedimentation, onshore construction, onshore land use changes	Onshore human-caused and naturally occurring erosion and sedimentation results from construction, maintenance, and weather events.	Ongoing onshore construction projects could generate noticeable disturbance in the landscape. Intensity and extent would vary depending on the location, type, and duration of activities.
Light: Offshore structures and vessels, onshore vehicles, roads, laydown, parking, facilities, equipment, and structures	Offshore vessels have an array of lights including navigational lights, deck lights, and interior lights. Various ongoing onshore and coastal construction projects have nighttime activities, as well as existing structures, facilities, and vehicles that would require nighttime lighting.	Ongoing onshore construction projects involving nighttime activity could generate nighttime lighting. Intensity and extent would vary depending on the location, type, direction, and duration of nighttime lighting.
Structures: Viewshed	Buoys are the only existing stationary structures within the offshore viewshed of the Project. Typically, buoys are visible only in the immediate foreground (less than 1 mile). Stationary and moving barges, boats, and ships also are visible in the daytime and nighttime viewsheds.	Onshore wind-related structures that could be viewed in conjunction with the offshore project components would be limited to meteorological towers, substations, and electrical transmission towers and conductors.
Traffic: Helicopters, vessels, vehicles	Ongoing activities contribute air, marine, and onshore traffic and visible congestion.	Planned onshore and offshore construction projects involving vessel, vehicle, and helicopter traffic could generate noticeable changes in the characteristic seascape and landscape and viewer experience. Intensity and extent of the changes would vary depending on the location, type, direction, and duration of the traffic.

Table D1-23. Summary of activities and the associated impact-producing factors for wetlands

Associated IPFs: Sub-IPFs	Ongoing Activities	Future Non-Offshore Wind Activities Intensity/Extent
Land disturbance: Erosion and sedimentation	Ground disturbance activities may lead to unvegetated or otherwise unstable soils. Precipitation events could potentially mobilize the soils into nearby wetlands, leading to potential erosion and sedimentation effects and subsequent increased turbidity.	Ground disturbance associated with construction and installation of onshore components could lead to unvegetated or unstable soils. Precipitation events could mobilize these soils, leading to erosion and sedimentation effects and turbidity.
Land disturbance: Onshore construction	Onshore construction activities may lead to unvegetated or otherwise unstable soils as well as soil contamination due to leaks or spills from construction equipment. Precipitation events could potentially mobilize the soils into nearby wetlands, leading to increased turbidity and alteration of water quality.	The general trend along coastal regions is that port activity and land development will increase modestly in the future. This increase in activity includes expansion needed to meet commercial, industrial, and recreational demand. Modifications to cargo-handling equipment and conversion of some undeveloped land to meet port demand would be required to receive the increase in larger ships.

Attachment 2: Maximum-Case Scenario Estimates for Offshore Wind Projects

The following tables provide maximum-case scenario estimates of potential offshore wind project impacts assuming maximum buildout within the SouthCoast Wind EIS geographic analysis areas. BOEM developed these estimates based on offshore wind demand, as discussed in its 2019 study *National Environmental Policy Act Documentation for Impact-Producing Factors in the Offshore Wind Cumulative Impacts Scenario on the North Atlantic Outer Continental Shelf* (BOEM 2019). Estimates disclosed in this EIS's Chapter 3, *Affected Environment and Environmental Consequences*, no action analyses were developed by summing acreage or number calculations across all lease areas noted as occurring within, or overlapping, a given geographic analysis area. This likely overestimates some impacts in cases where lease areas only partially overlap analysis areas. However, this approach was used to provide the most conservative estimate of future offshore wind development.

This page intentionally left blank.

Table D2-1. Offshore wind development activities on the U.S. East Coast: Projects and assumptions (Part 1, Turbine and Cable Design Parameters)

Region	Lease, Project, Lease Remainder [a]	Status	Geographic Analysis Area (X denotes lease area is within or overlaps geographic analysis area) [c]						Estimated Construction Schedule [d]	Turbine Number [e]	Generating Capacity (MW)	Offshore Export Cable Length (statute miles) [f]	Offshore Export Cable Installation Tool Disturbance Width (feet)	Interarray Cable Length (statute miles) [g]	Hub Height (feet) [h]	Rotor Diameter (feet) [h]	Height of Turbine (feet) [h]

	OCS Total [i,j]									**3,182**	**45,025**	**8,113**		**6,198**			

[a] The spacing/layout for projects are as follows: NE State water projects include a single strand of WTGs and no OSP. For projects in the RI, MA, NY, NJ, DE, MD lease areas, a 1×1–nm grid spacing is assumed. For the CVOW Project, the spacing is 0.7 nm; and the Dominion commercial lease area off the coast of Virginia would utilize 0.5 nm average spacing, which is less than the 1×1–nm spacing due to the need to attain the state's goals.
[b] Because development could occur anywhere within the RI and MA lease areas and assumes a continuous 1x1–nm grid, the actual development for these projects is expected to be approximately 88% of the collective technical capacity. Under the scenario described in this appendix, the total area in the RI and MA lease areas is greater than the area needed to meet state demand. Therefore, if a project is not constructed, BOEM assumes that another future project would be constructed to fulfill the unmet demand.
[c] This column identifies lease areas that are applicable to each resource based on the geographic analysis areas.
[d] The estimated construction schedule is based on information known at the time of this analysis and could be different when an applicant submits a COP.
[e] The number of turbines for those lease areas without an announced number of turbines has been calculated based on lease size, a 1×1-nm grid spacing, and/or the generating capacity.
[f] BOEM assumes that each offshore wind development would have its own cable (both onshore and offshore) and that future projects would not utilize a regional transmission line. The length of offshore export cable for those lease areas without a known project size is assumed to include two offshore cables totaling 120 miles (193 kilometers). The offshore export cable would be buried a minimum of 4 feet (1.8 meters) but not more than 10 feet (3.1 meters).

[3] The Final Sale Notice for Commercial Leasing for Wind Power Development on the OCS in the Gulf of Mexico was published on July 21, 2023. An auction was held on August 29, 2023; where Lake Charles, OCS-G 37334, received a winning bid from RWE Offshore US Gulf, LLC. On July 29, 2024, BOEM published a RFCI for two wind energy areas in the Gulf Mexico. The RFCI was published in the *Federal Register,* 89 FR 60913, for a 45-day public comment period, which ended on September 12, 2024.
[4] Within the geographic analysis area for marine mammals and sea turtles only.

[g] If information for a future project could not be obtained from a COP, the length of interarray cabling is assumed to be the average amount per foundation based on the COPs submitted to date, which is 1.48 miles (2.4 kilometers). In addition, for those lease areas that require more than one OSP, it is assumed that an additional 6.2 miles (9.9 kilometers) of inter-link cable would be required to link the two OSPs. Interarray cable is assumed to be buried between 4 and 6 feet.
[h] The hub height, rotor diameter, and turbine height for lease areas is based on worst-case scenario for the resource area. Presentation of heights vary by COP and may be presented relative to MLLW, mean sea level, or height above highest astronomical tide.
[i] BOEM recognizes that the estimates presented within this analysis are likely high, conservative estimates; however, BOEM believes that this analysis is appropriately capturing the potential cumulative impacts and errs on the side of maximum impacts. Totals by lease area and by OCS may not fully sum due to rounding errors.
[j] New York's demand is not double-counted, this total comes from looking at New York's state demand, not adding up the potential of the areas because that would double-count New York.
CT = Connecticut; CVOW = Coastal Virginia Offshore Wind; DE = Delaware; FDR = Facility Design Report; FIR = Fabrication and Installation Report; MA = Massachusetts; MD = Maryland; NC = North Carolina; NE = New England; NJ = New Jersey; NY = New York; PPA = Power Purchase Agreement; RAP = research activities plan; RI = Rhode Island; SAP = Site Assessment Plan

[a] This column identifies lease areas that are applicable to each resource based on the geographic analysis areas.
[b] Because development could occur anywhere within the RI and MA lease areas and assumes a continuous 1x1–nm grid, the actual development for these projects is expected to be approximately 88% of the collective technical capacity. Under the scenario described in this appendix, the total area in the RI and MA lease areas is greater than the area needed to meet state demand. Therefore, if a project is not constructed, BOEM assumes that another future project would be constructed to fulfill the unmet demand.
[c] The estimated number of foundations is the total number of turbines plus OSP. If information for a future project could not be obtained from a publicly available COP, it is assumed that for every 50 turbines there would be one OSP installed.
[d] If information for a future project could not be obtained from a publicly available COP, the foundation footprint is assumed to be 0.04 acre, which is based on the largest monopile reported (12 MW) for all lease areas.
[e] The seabed disturbance with the addition of scour protection was calculated based on scour protection expected in submitted COPs. If information for a future project could not be obtained from a publicly available COP, it is assumed that for all lease areas that a 12-MW foundation with addition of scour protection would be 0.85 acre per foundation.
[f] Offshore export cable seabed bottom disturbance is assumed to be due to installation of the export cable, the use of jack-up vessels, and the need to perform dredging. If information for a future project could not be obtained from a publicly available COP, export cable seabed disturbance assumed to be 6.06 acres per mile.
[g] If information for a future project could not be obtained from a publicly available COP, the offshore export cable operating seabed footprint assumed to be 0.4 acre per mile.
[h] If information for a future project could not be obtained from a publicly available COP, the offshore export cable hard protection is assumed to be similar to Vineyard Wind 1 Project, which is 0.357 acre per mile of offshore export cable.
[i] If information for a future project could not be obtained from a publicly available COP, anchoring disturbance for other lease areas is assumed to be a rate equal to 0.10 acre per mile of offshore export cable.
[j] If information for a future project could not be obtained from a publicly available COP, interarray construction seabed disturbance is assumed to be 6.06 acres per mile.
[k] If information for a future project could not be obtained from a publicly available COP, the interarray operating footprint is assumed to be a rate equal to the average amount per foundation of 1.43 acres per foundation.
[l] If information for a future project could not be obtained from a publicly available COP, the interarray cable hard protection is assumed to be zero.

[a] This column identifies lease areas that are applicable to each resource based on the geographic analysis areas.
[b] Quantities of coolant, oil and lubricants, and diesel fuel are scaled to SouthCoast Wind based on number turbines and OSP foundations.
[c] Because development could occur anywhere within the RI and MA lease areas and assumes a continuous 1x1–nm grid, the actual development for these projects is expected to be approximately 88% of the collective technical capacity. Under the scenario described in this appendix, the total area in the RI and MA lease areas is greater than the area needed to meet state demand. Therefore, if a project is not constructed, BOEM assumes that another future project would be constructed to fulfill the unmet demand.

Appendix E: Analysis of Incomplete and Unavailable Information

In accordance with Section 1502.21 of the Council on Environmental Quality (CEQ) regulations implementing the National Environmental Policy Act (NEPA), when an agency is evaluating reasonably foreseeable significant adverse effects on the human environment in an Environmental Impact Statement (EIS) and when information is incomplete or unavailable, the agency shall make clear that such information is lacking. When incomplete or unavailable information was identified, the Bureau of Ocean Energy Management (BOEM) considered whether the information was relevant to the assessment of impacts and essential to its analysis of alternatives based upon the resource analyzed. If essential to a reasoned choice among the alternatives, BOEM considered whether it was possible to obtain the information and if the cost of obtaining it was exorbitant. If it could not be obtained or if the cost of obtaining it was exorbitant, BOEM applied acceptable scientific methodologies to inform the analysis in light of this incomplete or unavailable information. For example, conclusive information on many impacts of the offshore wind industry may not be available for years, and certainly not within the contemplated timeframe of this NEPA process. However, if this information is essential for a reasoned decision, subject matter experts have used the scientifically credible information available and generally accepted scientific methodologies to evaluate impacts on the resources while this information is unavailable. The following sections present an analysis by resource topic of incomplete or unavailable information in the EIS for the SouthCoast Wind Project (Project) proposed by SouthCoast Wind Energy LLC (SouthCoast Wind) in its Construction and Operations Plan (COP) (SouthCoast Wind 2024) within Lease Area OCS-A 0521 (Lease Area).

E.1 Incomplete or Unavailable Information Analysis for Resource Areas

E.1.1 Physical Resources

E.1.1.1 Air Quality

Although a quantitative emissions inventory analysis of the region, or regional modeling of pollutant concentrations, over the next 35 years would more accurately assess the overall impacts of the changes in emissions from the Project, any action alternative would lead to reduced emissions regionally and can only lead to a net improvement in regional air quality. The differences among action alternatives with respect to direct emissions due to construction, operations and maintenance (O&M), and decommissioning of the Project are expected to be small. As such, the analysis provided in this EIS is sufficient to support sound scientific judgments and informed decision-making related to the use of the offshore portions of the Wind Farm Area and offshore export cable route corridors. Therefore, BOEM does not believe that there is incomplete or unavailable information on air quality that is essential to a reasoned choice among alternatives.

E.1.1.2 Water Quality

No incomplete or unavailable information related to the analysis of impacts on water quality was identified.

E.1.2 Biological Resources

E.1.2.1 Bats

There will always be some level of incomplete information on the distribution and habitat use of bats in the offshore portions of the Lease Area, as habitat use and distribution varies among seasons and species. Additionally, surveying bat activity offshore provides challenges as limited methods have been developed and tested for surveying within this environment. No BOEM issued guidance for bat surveys currently exist for renewable energy development on the outer continental shelf (OCS). Although SouthCoast Wind did not complete Project-specific surveys within the Project area, the evaluation of several studies was examined to provide a baseline understanding of the presence, abundance, and seasonality of bats which may occur within the Project area (including the OCS, State Waters, and coastal lands of Massachusetts and Rhode Island) and the northeast, and an examination of the terrestrial natural communities within the Onshore Project area. Additionally, because U.S. offshore wind development is in its infancy, with only two offshore wind projects having been constructed at the time of this analysis, there is some level of uncertainty regarding the potential collision risk to individual bats that may be present within the offshore portions of the Wind Farm Area. However, sufficient information on collision risk to bats observed at land-based U.S. wind projects exists and was used to analyze and corroborate the potential for this impact as a result of the proposed Project. In addition, the likelihood of a bat encountering an operating wind turbine generator (WTG) during migration is very low and, therefore, the differences among action alternatives with respect to bats for the Project are expected to be small. As such, the analysis provided in this EIS is sufficient to support sound scientific judgments and informed decision-making related to bat use of the Wind Farm Area and the potential for collision risk of bats. Therefore, BOEM does not believe that there is incomplete or unavailable information on bat resources that is essential to a reasoned choice among alternatives.

E.1.2.2 Benthic Resources

Although there is uncertainty regarding the spatial and temporal distribution of benthic (faunal) resources and periods during which they might be especially vulnerable to disturbance, SouthCoast Wind's surveys of benthic resources and other broad-scale studies (SouthCoast Wind 2024; Guida et al. 2017) provided this suitable basis for generally predicting the species, abundances, and distributions of benthic resources within the geographic analysis area. Surveys have not been completed for any of the alternative offshore export cable routes (Alternatives C-1 and C-2) where they diverge from the Proposed Action cable corridors. BOEM is relying on general information and the surveys of the Proposed Action cable corridors, which are in close proximity to the alternative cable routes to characterize benthic habitat impacts. Uncertainty also exists regarding the impact of some impact-producing factors (IPFs) on benthic resources. For example, specific stimulus-response related to acoustics and electromagnetic fields (EMF) is not well studied, although there is some emerging information from benthic monitoring at European wind facilities and the Block Island Wind Farm in the United States that allows for a broad understanding of the impacts. Similarly, specific secondary impacts, such as changes in diets throughout the food chain resulting from habitat modification and synergistic behavioral impacts from multiple IPFs, are not fully known. Again, results of benthic monitoring at European wind facilities and the Block Island Wind Farm in the United States provide general knowledge of the overall impacts of these IPFs combined, if not individually. Therefore, the analysis provided in this EIS is sufficient to support sound scientific judgments and informed decision-making related to the overall impacts. For these reasons, BOEM does not believe that there is incomplete or unavailable information on benthic resources that is essential to a reasoned choice among alternatives.

E.1.2.3 Birds

Habitat use and distribution of marine birds varies between seasons, species, and years and, as a result, there will always be some level of incomplete information on the distribution and habitat use of marine birds in the offshore portions of the geographic analysis area. However, in accordance with BOEM guidance (BOEM 2020 a-b), an Avian Exposure Risk Assessment was completed for SouthCoast Wind (COP Appendix I1; SouthCoast Wind 2024) to use the best-available marine avian species information with potential to occur in the OCS Lease Area with consideration of several quantitative, qualitative, and spatially explicit resources available for select species occurrences at multiple scales. The Avian Exposure Risk Assessment incorporated baseline regional information, and site-specific data collected during SouthCoast Wind-sponsored high-definition aerial surveys and opportunistic ship-based surveys in order to evaluate the marine bird occurrences in the Lease Area with a specific focus on federally or state listed species and potentially sensitive species that are believed to be susceptible to displacement or collision. These findings were used to inform the predictive models and analyze the potential adverse impacts on bird resources in the EIS.

Because U.S. offshore wind development is in its infancy, there will always be some level of uncertainty regarding the potential for collision risk and avoidance behaviors for some of the bird species that may be present within the offshore portions of the geographic analysis area. In place of this information, subject matter experts used the data and assumptions described below and in the EIS to create models to evaluate impacts, where it was determined that the information was essential for reasoned decision-making. Bird mortality data are available for onshore wind facilities and, based on a number of assumptions regarding their applicability to offshore environments, were used to inform the analysis of bird mortality associated with the offshore WTGs analyzed in the EIS. However, uncertainties exist regarding the use of the onshore bird mortality rate to estimate the offshore bird mortality rate due to differences in species groups present and life history and behavior of species as well as differences in the offshore marine environment compared to onshore habitats. Modeling is commonly used to predict the potential mortality rates for marine bird species in Europe and the United States (BOEM 2015, 2021). Due to inherent data limitations, these models often represent only a subset of species potentially present. However, the datasets used by both SouthCoast Wind and BOEM to assess the potential for exposure of marine birds to the Wind Farm Area represent the best available data and provide context at both local and regional scales. Furthermore, sufficient information on collision risk and avoidance behaviors observed in related species at European offshore wind projects is available and was used to analyze and corroborate the potential for these impacts as a result of the proposed Project (e.g., Skov et al. 2018). As such, the analysis provided in the EIS is sufficient to support sound scientific judgments and informed decision-making related to distribution and use of the offshore portions of the geographic analysis area as well as to the potential for collision risk and avoidance behaviors in bird resources. Furthermore, the similarity between the layouts analyzed for the different action alternatives does not render any of this incomplete and unavailable information essential to a reasoned choice among alternatives. Therefore, BOEM does not believe that there is incomplete or unavailable information on avian resources that is essential to a reasoned choice among alternatives.

E.1.2.4 Coastal Habitat and Fauna

Although the preferred habitats of terrestrial and coastal fauna are generally known, specific data on abundances and distributions within the geographic analysis area of various fauna within these habitats are likely to remain unknown without site-specific surveys. However, the species inventories and other general information about the area provide an adequate basis for evaluating the fauna likely to inhabit the onshore geographic analysis area. Additionally, the onshore activities proposed involve only common, industry-standard activities for which impacts are generally understood. Therefore, BOEM believes that the analysis provided in this EIS is sufficient to make a reasoned choice among the alternatives.

E.1.2.5 Finfish, Invertebrates, and Essential Fish Habitat

Although there is some uncertainty regarding the spatial and temporal distribution of finfish and invertebrate resources and periods during which they might be especially vulnerable to disturbance, SouthCoast Wind's site assessment surveys and other broad-scale studies (e.g., Guida et al. 2017) provided a suitable basis for general predictions of finfish and invertebrate resources with respect to species, densities, and distributions within the geographic analysis area. Additional information related to species listed under the Endangered Species Act (ESA) and essential fish habitat (EFH) are addressed in the biological assessment (BA) and EFH Assessment. While impacts on these specific finfish and invertebrate species are not anticipated to vary from the general impacts provided in the EIS, specific impact discussion for ESA-listed species and EFH will be provided in the BA and EFH Assessment. Site assessment surveys have not been completed for any of the alternative offshore export cable routes (Alternatives C-1 and C-2) where they diverge from the Proposed Action cable corridors. BOEM is relying on general information and the assessment surveys of the Proposed Action cable corridors, which are in close proximity to the alternative cable routes to characterize habitat impacts for finfish, invertebrates, and EFH.

Uncertainty also exists regarding the impact of some IPFs on invertebrate resources, such as the effects of EMFs and underwater noise (e.g., generated from pile driving). The available information on invertebrate sensitivity to EMF is equivocal (Hutchinson et al. 2020), and sensitivity to sound pressure and particle motion effects is not well understood for many species, nor are synergistic or antagonistic impacts from multiple IPFs. Similarly, specific secondary impacts such as changes in diets throughout the food chain resulting from habitat modification are not well known for finfish and invertebrates. Lastly, the nature, extent, and significance of potential spillover effects on broader ecosystem functions, such as larval dispersal, are not fully understood (van Berkel et al. 2020). Where applicable, the assessment drew upon information in the available literature and an increasing number of monitoring and research studies related to wind development, other undersea development, or artificial reefs in Europe and the United States, several of which were recently drafted or published. These monitoring studies help provide a broad understanding of the overall impacts of these IPFs combined, if not individually.

For these reasons, the information provided in this EIS is sufficient to support sound scientific judgments and informed decision-making related to the overall impacts. Therefore, BOEM does not believe that there is incomplete or unavailable information on finfish, invertebrate, and EFH resources that is essential to a reasoned choice among alternatives.

E.1.2.6 Marine Mammals

The National Marine Fisheries Service (NMFS) has summarized the most current information about marine mammal population status, occurrence, and use of the region in its 2020 stock status report for the Atlantic OCS and Gulf of Mexico (Hayes et al. 2020, 2021). These studies provided a suitable basis for predicting the species, abundances, and distributions of marine mammals in the geographic analysis area. However, population trend data from NMFS are unavailable for 24 species, and annual human-caused mortality is unknown for 16 species (Appendix B, *Supplemental Information and Additional Figures and Tables*). The majority of species lacking population trend data are offshore species, such as blue whale, fin whale, and non-porpoise odontocetes (e.g., beaked whales and dolphins). As a result, there is uncertainty regarding how Project activities and cumulative effects may affect these populations. In addition to species distribution information, effects of some IPFs on marine mammals are also uncertain or ambiguous, as described below.

Potential effects of EMF have not been scaled to consider impacts on marine mammal populations or their prey in the geographic analysis area (Taormina et al. 2018). The widespread ranges of marine mammals and difficulty obtaining permits make experimental studies challenging. As a result, no scientific studies have been conducted that examine the effects of altered EMF on marine mammals. However, although scientific studies summarized by Normandeau et al. (2011) demonstrate that marine mammals are sensitive to, and can detect, small changes in magnetic fields (Section 3.5.6, *Marine Mammals*), potential impacts would likely only occur within a few feet of cable segments. The current literature does not support a conclusion that EMF could lead to changes in behavior that would cause significant adverse effects on marine mammal populations.

The behavioral effects of anthropogenic noises on marine mammals are increasingly being studied; however, behavioral responses vary depending on a variety of factors such as life stage, previous experience, and current behavior (e.g., feeding, nursing) and are, therefore, difficult to predict. In addition, the current NMFS disturbance criteria apply a single threshold for all marine mammals for impulsive noise sources and do not consider the overall duration, exposure, or frequency distribution of the sound to account for species-dependent hearing acuity. While elevated underwater sound could startle or displace animals, behavioral responses are not necessarily predictable from source levels alone (Southall et al. 2007).

In addition, research regarding the potential behavioral effects of pile-driving noise has generally focused on harbor porpoises and seals; studies that examine the behavioral responses of baleen whales to pile driving are absent from the literature. Of the available research, most studies conclude that, although pile-driving activities could cause avoidance behaviors or disruption of feeding activities, individuals would likely return to normal behaviors once the activity had stopped. However, uncertainty remains regarding the long-term cumulative acoustic impacts associated with multiple pile-driving projects that may occur over a number of years. This also applies to other project activities such as vessel movements, high-resolution geophysical (HRG) surveys, geotechnical drilling, and dredging activities that may elicit behavioral reactions in marine mammals. As a result, it is not possible to predict with certainty the potential long-term behavioral effects on marine mammals from Project-related pile driving or other activities, as well as ongoing concurrent and cumulative pile driving and other activities.

Offshore WTGs produce continuous, non-impulsive underwater noise during operation, mostly in lower-frequency bands below 1,500 Hz. SPLs measured from WTGs within the size range likely to be utilized by this Project do not currently exist in the literature, and modeling scenarios are limited to two studies with a high degree of uncertainty. It is likely that source levels and frequencies emitted from the larger WTGs to be used for the Project would fall somewhere between those recorded for smaller-gear driven WTGs (e.g., 109 to 128 dB re 1 µPa SPL_{RMS} [at varying distances]) (Lindeboom et al. 2011; Pangerc et al. 2016; Tougaard et al. 2009) and those modeled in Stöber and Thomsen (2021) (e.g., 170 to 177 dB re 1 µPa SPL_{RMS}). Using the least-squares fits from Tougaard et al. (2020), SPLs from 11.5-MW turbines (in 20-meter-per-second, gale-force wind) would be expected to fall below the 120 dB re 1 µPa behavioral threshold within about 800 feet (245 meters). In lighter, 10-meter-per-second winds (approximately 20 knots), the predicted range to threshold would be only about 460 feet (140 meters). Effects related to the large WTGs to be used for the Project would include behavioral and masking effects. Masking of the low-frequency calls emitted from LFC and phocid pinnipeds in water would be more likely to occur. However, without further information regarding these larger WTGs, the extent of these effects is unknown.

To address this uncertainty, the assessment used the best available information when considering behavioral effects related to underwater noise. To better characterize these impacts, all potential types of behavioral responses, as well as the context within which these responses may occur, were considered following guidance from applicable studies (Southall et al. 2021) and used in conjunction with the NMFS disturbance threshold, as described in Chapter 3, Section 3.5.6, *Marine Mammals*. For the assessment of large baleen whales, studies on other impulsive noises (e.g., seismic sources) were used to inform the potential behavioral reactions to pile-driving noise. Monitoring studies would provide insight into species-specific behavioral reactions to Project-generated underwater noise. Long-term monitoring of concurrent and multiple projects could inform the understanding of long-term effects and subsequent consequences from cumulative underwater noise activities on marine mammal populations.

There is a lack of research regarding the responses of large whale species to extensive networks of new structures due to the novelty of this type of development on the Atlantic OCS. Although new structures are anticipated from multiple offshore wind projects under the planned activities scenario, it is expected that spacing will allow large whales to access areas within and between wind facilities. No physical obstruction of marine mammal migration routes or habitat areas are anticipated, but whether avoidance of offshore wind lease areas will occur due to new structures is unknown. Additionally, while there is some uncertainty regarding how hydrodynamic changes around foundations may affect prey availability, these changes are expected to have limited impacts on the local conditions around WTG foundations. The potential consequences of these impacts on marine mammals are unknown. Monitoring studies would provide insight into species-specific avoidance behaviors and other potential behavioral reactions to Project structures.

At present, this EIS has no basis to conclude that these IPFs would result in significant adverse impacts on marine mammal populations.

BOEM determined that the overall costs of obtaining the missing information for or addressing these uncertainties are exorbitant, or the means to obtain it are not known. Therefore, to address these gaps as described above, BOEM extrapolated or drew assumptions from known information for similar species and studies using acceptable scientific methodologies to inform the analysis in light of this incomplete or unavailable information, as presented in Chapter 3, Section 3.5.6, *Marine Mammals*, and in the BA submitted to NMFS (BOEM 2022). The information and methods used to predict potential impacts on marine mammals represent the best available information, and the information provided in this EIS is sufficient to support sound scientific judgments and informed decision-making. Therefore, BOEM does not believe that there is incomplete or unavailable information on marine mammal resources that is essential to a reasoned choice among alternatives.

E.1.2.7 Sea Turtles

The NMFS BA (BOEM 2022) provides a thorough overview of the available information about potential species occurrence and exposure to Project-related IPFs. The studies summarized therein provide a suitable basis for predicting potential species occurrence, relative abundance, and probable distribution of sea turtles in the geographic analysis area. There are Protected Species Observer sightings and modeled densities of sea turtle species expected to occur within the Project Area outlined in the most recent COP submission (SouthCoast Wind 2024). However, without specific sea turtle surveys or monitoring guidelines, data to investigate impacts on sea turtles is lacking.

Some uncertainty exists about the effects of certain IPFs on sea turtles and their habitats. The effects of EMF on sea turtles are not completely understood. However, the available relevant information is summarized in the BOEM-sponsored report by Normandeau et al. (2011). Although the thresholds for EMF disturbing various sea turtle behaviors are not known, the evidence suggests that impacts may only occur on hatchlings over short distances, and no adverse effects on sea turtles have been documented to occur from the numerous submarine power cables around the world.

There is also uncertainty about sea turtle responses to proposed Project construction activities, and data are not available to evaluate potential changes to movements of juvenile and adult sea turtles due to elevated suspended sediments. However, although some exposure may occur, total suspended solid impacts would be limited in magnitude and duration and would occur within the range of exposures periodically experienced by these species. On this basis, any resulting impact on sea turtle behavior due to sediment plumes would likely be too small to be biologically meaningful, and no adverse impacts would be expected (NOAA 2020). Some potential exists for sea turtle displacement, but it is unclear if this would result in adverse impacts (e.g., because of lost foraging opportunities or increased exposure to potentially fatal vessel interactions). Additionally, it is currently unclear whether concurrent construction of multiple projects, increasing the extent and intensity of impacts over a shorter duration, or spreading out project construction with lower-intensity impacts over multiple years would result in the least potential harm to sea turtles.

Information on sea turtle hearing is limited, and there are some discrepancies between hearing range determinations. Cumulative acoustic impacts associated with pile-driving activities are unknown, including whether sea turtles affected by construction activities would resume normal feeding, migrating, or breeding behaviors once daily pile-driving activities cease, or if secondary impacts would continue. Under the planned activities scenario, individual sea turtles may be exposed to acoustic impacts from multiple projects in a single day or from one or more projects over the course of multiple days. Although the consequences of these exposure scenarios have been analyzed with the best available information, some level of uncertainty remains due to the lack of observational data on species' responses to pile driving.

Since U.S. offshore wind development is in its infancy, there is some level of uncertainty regarding the potential collision risk to sea turtles that may be present within the offshore portions of the Wind Farm Area. The potential for sea turtle responses to Federal Aviation Administration hazard lights and navigation lighting is unknown. SouthCoast Wind would limit lighting on WTGs and offshore substation platforms to minimum levels required by regulation for worker safety, navigation, and aviation. Although sea turtles' sensitivity to these minimal light levels is unknown, sea turtles do not appear to be adversely affected by oil and gas platform operations, which produce far more artificial light than offshore wind structures. The placement of new structures would be far from nesting beaches, so no impacts on nesting female or hatchling sea turtles are anticipated.

Considerable uncertainty exists about how sea turtles would interact with the long-term changes in biological productivity and community structure resulting from the reef effect of offshore wind farms across the geographic analysis area. Artificial reef and hydrodynamic impacts could influence predator-prey interactions and foraging opportunities in ways that influence sea turtle behavior and distribution. Also, the extent of sea turtle entanglement on artificial reefs and shipwrecks is not captured in sea turtle stranding records and the significance and potential scale of sea turtle entanglement in lost fishing gear are not quantified. These impacts are expected to interact with the ongoing influence of climate change on sea turtle distribution and behavior over broad spatial scales, but the nature and significance of these interactions are not predictable. BOEM anticipates that ongoing monitoring of offshore energy structures will provide some useful insights into these synergistic effects.

BOEM considered the level of effort required to address the uncertainties described above for sea turtles and determined that the methods necessary to do so are lacking or the associated costs would be exorbitant. Therefore, where appropriate, BOEM inferred conclusions about the likelihood of potential biologically significant impacts from available information for similar species and situations to inform the analysis in light of this incomplete or unavailable information. These methods are described in greater detail in Section 3.5.7, *Sea Turtles*, and in the BA submitted to NMFS (BOEM 2022). Therefore, the analysis provided is sufficient to support sound scientific judgments and informed decision-making about the proposed Project with respect to its impacts on sea turtles. For these reasons, BOEM does not believe that there is incomplete or unavailable information on turtles that is essential to a reasoned choice among alternatives.

E.1.2.8 Wetlands

The analysis of impacts on wetlands presented in Section 3.5.8, *Wetlands*, is based on publicly available data sets, including National Wetland Inventory, Massachusetts Bureau of Geographic Information wetlands dataset, and the University of Rhode Island Environmental Data Center and Rhode Island Geographic Information System Wetlands dataset. SouthCoast Wind delineated wetlands during field surveys conducted within the onshore substation sites in Falmouth; however, the field delineation report for the onshore substation sites under consideration in Falmouth is private data and, therefore, has not been provided (COP Volume 2, Section 6.4.1.1; SouthCoast Wind 2024). Additional field delineations will be completed as part of the federal (Clean Water Act Section 404) and state permitting processes as necessary. While delineated wetland data provides more accurate and site-specific impact information, use of the national and state wetland data provides adequate detail to characterize impacts on wetlands and any differences among the alternatives. Based on the foregoing, BOEM does not believe that there is incomplete or unavailable information on wetlands that is essential to a reasoned choice among alternatives.

E.1.3 Socioeconomic Conditions and Cultural Resources

E.1.3.1 Commercial Fisheries and For-Hire Recreational Fishing

Fisheries are managed in the context of an incomplete understanding of fish stock dynamics and effects of environmental factors on fish populations. The commercial fisheries information used in this assessment has limitations. For example, vessel trip report data are only an approximation because this information is self-reported and may not account for all trips. The vessel trip report data also do not include all commercial fishing operations that may be affected by the Proposed Action and only represent vessel logbook data for species managed by the Greater Atlantic Regional Fisheries Office. Additionally, available historical data lack consistency, making comparisons challenging.

Vessel Monitoring System (VMS) data are also limited, with a number of factors contributing to their limitations.

- VMS coverage is not universal for all fisheries, with some fisheries (summer flounder, scup, black sea bass, bluefish, American lobster, spiny dogfish, skate, whiting, and tilefish) not covered at all by VMS.
- There is limited historical coverage for most fisheries (e.g., monkfish is optional and elective on a yearly basis, 2005 or earlier for herring, 2006 for groundfish and scallops, 2008 for surfclams/ocean quahogs, 2014 for mackerel, and 2016 for longfin squid/butterfish).
- Trip declaration does not necessarily correspond to actual operation.
- Hourly position pings limit area resolution based on speed.
- Fishing time/location can be mis-estimated by operational assumptions (speed and direction) that are affected by externalities (weather, sea state, mechanical issues).
- Catch data are limited because there is no information on catch rates, retained catch composition is limited to target species and some bycatch species, and the data are not universal.
- Catch information is for the full trip, not sub-trips.
- Not all information is collected from all fisheries (gear type).

However, these data represent the best available data, and sufficient information exists to support the findings presented in this EIS.

A second limitation is that recent annual exposure of revenue for for-hire recreational fishing specific to the Lease Area is not available. The economic analysis conducted by BOEM of recreational for-hire boats, as well as for-hire and private-boat angler trips that might be affected by the overall Massachusetts Wind Energy Area (WEA), including the Lease Area, was conducted for 2007–2012 (Kirkpatrick et al. 2017), and the Massachusetts WEA is treated as one entity with no site-specific data for the individual offshore wind lease areas that compose the Massachusetts WEA. Currently, there are an insufficient number of trips available for NMFS to generate a description of selected fishery landings and estimates of recreational party and charter vessel revenue from within the Project area (NMFS 2021). Due to the low effort in the area, BOEM does not believe that there is incomplete or unavailable information on commercial fisheries and for-hire recreational fishing resources that is essential to a reasoned choice among alternatives.

E.1.3.2 Cultural Resources

BOEM requires detailed information regarding the nature and location of historic properties that may be affected by an applicant’s proposed activity in order to conduct review of the COP under Section 106 of National Historic Preservation Act (54 United States Code 306108). The assessment of effects from the proposed Project on historic properties is reliant on the identification and analysis of cultural resources in the geographic area in which these activities are proposed to take place (referred to as the Area of Potential Effects [APE]). BOEM has determined that there is sufficient information on cultural resources in the APE for the proposed Project that allows for the assessment of impacts, analysis and comparison of alternatives, and Finding of Adverse Effect on historic properties.

For the Terrestrial Archaeological Resource Assessment (TARA), BOEM requires a complete inventory of terrestrial archaeological resources in the terrestrial APE to assess Project impacts and complete the analysis of alternatives based on specific historic properties. SouthCoast Wind will be using a process of phased identification and evaluation of historic properties as defined in 36 Code of Federal Regulations (CFR) 800.4(b)(2) to provide BOEM with the full completion of historic property identification in the terrestrial APE. This includes completion of Phase IB terrestrial archaeological survey in presently unsurveyed areas. Any thus-far known terrestrial archaeological resources identified as being located in the APE are provided in the TARA; however, additional terrestrial archaeological surveys completed for the proposed Project may lead to the identification of additional terrestrial archaeological resources. This process of phased identification and evaluation of historic properties will be stipulated in the MOA, as developed through BOEM's NHPA Section consultations with federally recognized Tribes and consulting parties (Appendix I, Attachment A) and will be completed following the execution of the MOA.

In conclusion, BOEM has determined there is sufficient information on cultural resources in the geographic analysis area and APE for the analysis in this Final EIS to support a reasoned choice among alternatives.

E.1.3.3 Demographics, Employment, and Economics

SouthCoast Wind's economic analysis estimated the employment and outputs for the Proposed Action. This provided sufficient information for the evaluation of demographics, employment, and economics to support a reasoned choice among alternatives. There is some inherent uncertainty in forecasting how economic variables in various areas will evolve over time. However, the differences among action alternatives with respect to demographics, employment, and economics are not expected to be significant. Therefore, BOEM does not believe that there is specific incomplete or unavailable information on demographics, employment, and economics that is essential to a reasoned choice among alternatives.

E.1.3.4 Environmental Justice

Evaluations of impacts on environmental justice communities rely on the assessment of impacts on other resources. As a result, incomplete or unavailable information related to other resources, as described in this document, also affect the completeness of the analysis of impacts on environmental justice communities.

As discussed in other sections, BOEM has determined that incomplete and unavailable resource information for environmental justice or for other resources on which environmental justice communities rely was either not relevant to assess reasonably foreseeable significant adverse impacts, was not essential to a reasoned choice among alternatives, alternative data or methods could be used to predict potential impacts and provided the best available information, or the overall costs of obtaining the information were exorbitant or the means to do so were unknown. Therefore, the information provided in the EIS is sufficient to support sound scientific judgments and informed decision-making related to the proposed uses of the onshore and offshore portions of the geographic analysis area. Furthermore, the differences among action alternatives with respect to environmental justice are not expected to be significant.

E.1.3.5 Land Use and Coastal Infrastructure

There is no incomplete or unavailable information related to the analysis of impacts on land use and coastal infrastructure.

E.1.3.6 Navigation and Vessel Traffic

SouthCoast Wind's Navigation Safety Risk Assessment (COP Appendix X; SouthCoast Wind 2024), of which the navigation and vessel traffic impact analysis in the EIS is largely based, relies on 1 year's (January 1–December 31, 2021) Automatic Identification System (AIS) data from vessels required to carry AIS (i.e., those 65 feet [19.8 meters] or greater in length). To account for some gaps in the data due to limitations of the AIS carriage requirements, additional vessel transits were added to the Navigation Safety Risk Assessment risk modeling to account for both current and future traffic not represented in the data (COP Appendix X; SouthCoast Wind 2024). The AIS data and additional vessel trips added to the modeling described above represents the best available vessel traffic data and is sufficient to enable BOEM to make a reasoned choice among alternatives.

As stated in Section 3.6.6, *Navigation and Vessel Traffic*, WTGs could potentially interfere with marine radars. Marine radars have varied capabilities and the ability of radar equipment to properly detect objects is dependent on radar type, equipment placement, and operator proficiency; however, trained radar operators, properly installed and adjusted vessel equipment, marked wind turbines, and the use of AIS all would enable safe navigation with minimal loss of radar detection. Based on the foregoing, BOEM does not believe that there is incomplete or unavailable information on navigation and vessel traffic that is essential to a reasoned choice among alternatives.

E.1.3.7 Other Uses (Marine Minerals, Military Use, Aviation, Scientific Research, and Surveys)

There is no incomplete or unavailable information related to the analysis of impacts on other uses.

E.1.3.8 Recreation and Tourism

Evaluations of impacts on recreation and tourism rely on the assessment of impacts on other resources. As a result, incomplete or unavailable information related to other resources, as described in this document, also affect the completeness of the analysis of impacts on recreational tourism. BOEM has determined that incomplete and unavailable resource information for recreation and tourism or for other resources on which the analysis of recreation and tourism impacts rely was either not relevant to reasonably foreseeable significant adverse impacts, was not essential to a reasoned choice among alternatives, alternative data or methods could be used to predict potential impacts and provided the best available information, or the overall costs of obtaining the information were exorbitant or the means to do so were unknown. Therefore, the information provided in the EIS is sufficient to support sound scientific judgments and informed decision-making related to the proposed uses of the onshore and offshore portions of the geographic analysis area.

E.1.3.9 Visual Resources

No incomplete or unavailable information related to the analysis of impacts on scenic and visual resources was identified.

Appendix F: Analysis of Alternatives to Inform the USACE's 404(b)(1) Alternatives Analysis

The purpose of this appendix is to help inform the U.S. Army Corps of Engineers' (USACE) 404(b)(1) Guidelines alternatives analysis and their selection of the Least Environmentally Damaging Practicable Alternative (LEDPA). This appendix describes alternatives that were considered and the reasons they were not carried forward.

The U.S. Environmental Protection Agency (EPA)'s Clean Water Act (CWA) Section 404(b)(1) guidelines (Guidelines) can be found at 40 Code of Federal Regulations (CFR) Part 230 and apply to the USACE's review of proposed discharges of dredged or fill material into waters of the United States regulated under CWA Section 404. In tidal waters, the shoreward limit of Section 404 jurisdiction is the high tide line, while the seaward limit is 3 nautical miles from the baseline of the territorial seas. In non-tidal waters, the Section 404 jurisdictional limit is the ordinary high water (OHW) mark of a waterbody. When adjacent wetlands are present, Section 404 jurisdiction extends beyond the OHW mark to the limit of the adjacent wetlands. The Guidelines also address impacts on "special aquatic sites," (defined at 40 CFR 230.3(m) and identified in 40 CFR 230 subpart E) which are geographic areas, large or small, possessing special ecological characteristics of productivity, habitat, wildlife protection, or other important and easily disrupted ecological values. Special aquatic sites include wetlands, sanctuaries and refuges, vegetated shallows (such as eelgrass), mud flats, coral reefs, and riffle and pool complexes.

Except as provided under CWA Section 404(b)(2), no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences. An alternative is practicable if it is available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes.

Where the activity associated with a discharge which is proposed for a special aquatic site does not require access or proximity to or siting within the special aquatic site in question to fulfill its basic purpose (i.e., is not ''water dependent''), practicable alternatives that do not involve special aquatic sites are presumed to be available, unless clearly demonstrated otherwise. In addition, where a discharge is proposed for a special aquatic site, all practicable alternatives to the proposed discharge which do not involve a discharge into a special aquatic site are presumed to have less adverse impact on the aquatic ecosystem, unless clearly demonstrated otherwise.

For the proposed SouthCoast Wind Project, USACE has determined that the basic project purpose is offshore wind energy generation, which is not "water dependent" per the Section 404(b)(1) Guidelines. The following information (including alternatives tables for Falmouth and Brayton Point) includes a description of alternatives considered that was provided by SouthCoast Wind and will be analyzed according to the appropriate criteria in the Guidelines.

The SouthCoast Wind proposed offshore export cable routes, SouthCoast Wind proposed landfall sites and onshore export cable routes, and BOEM alternative onshore routes for Alternative C-1 and Alternative C-2 routes are described below (Figure F-1, Figure F-2, Figure F-3, Figure F-4, Figure F-5, Figure F-6, and Figure F-7).

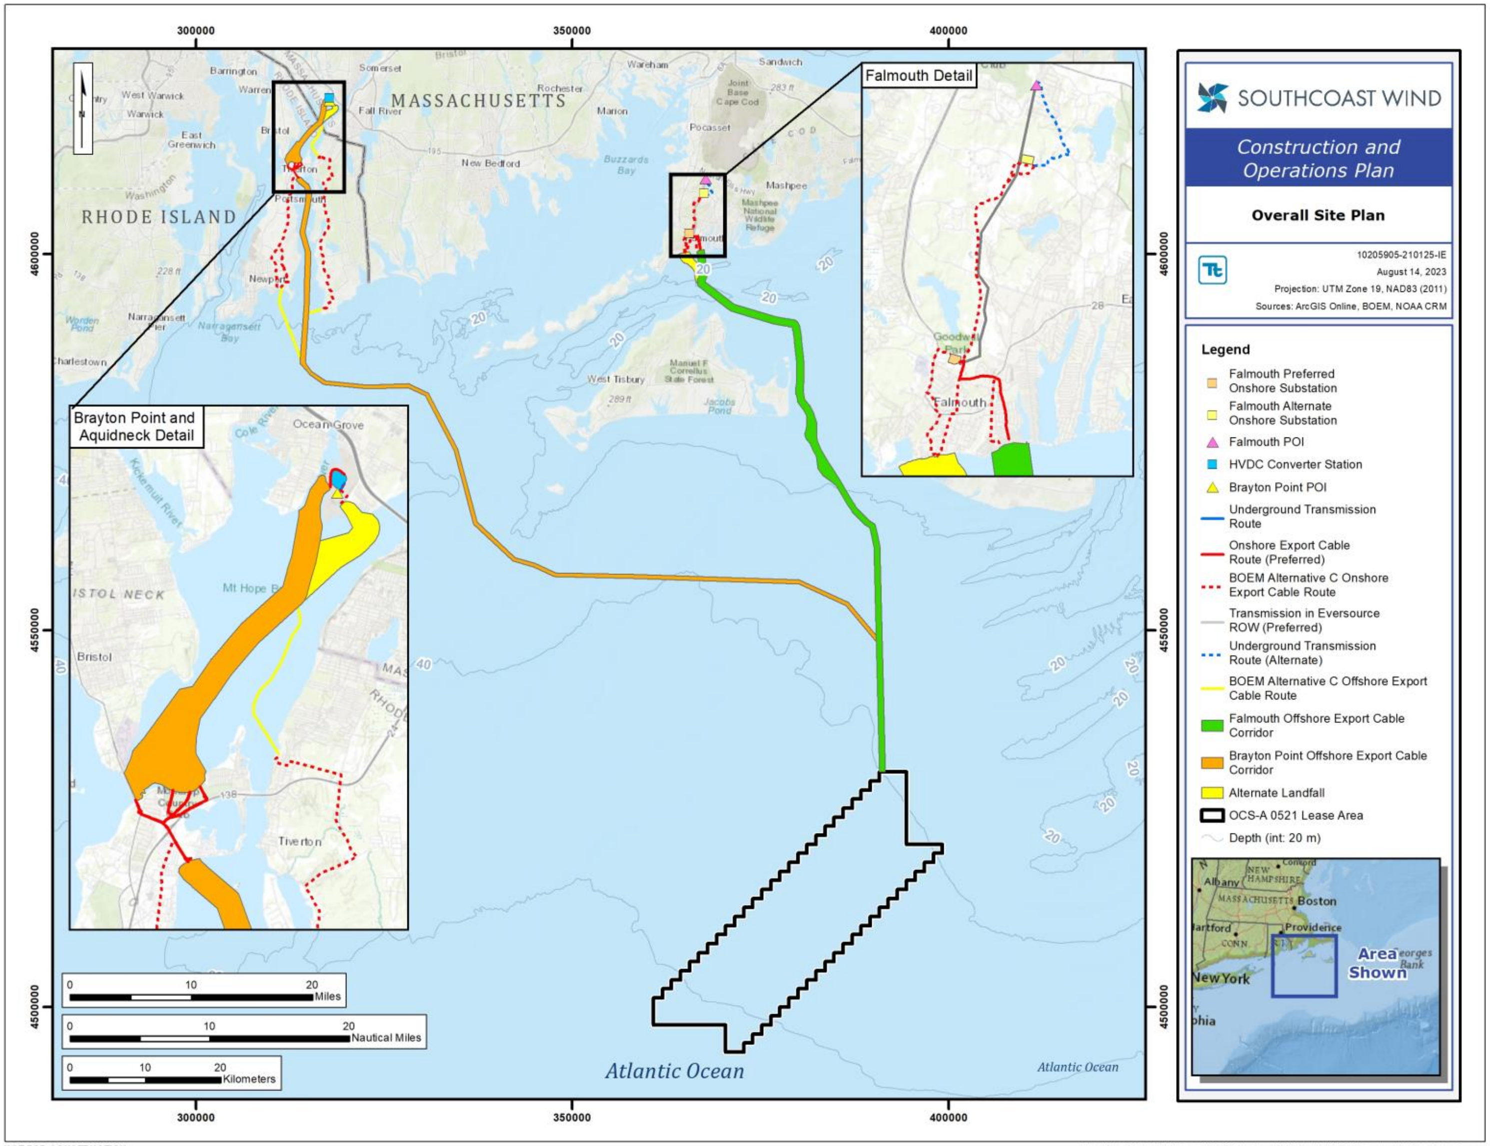

Figure F-1 Proposed Offshore Export Cable Routes

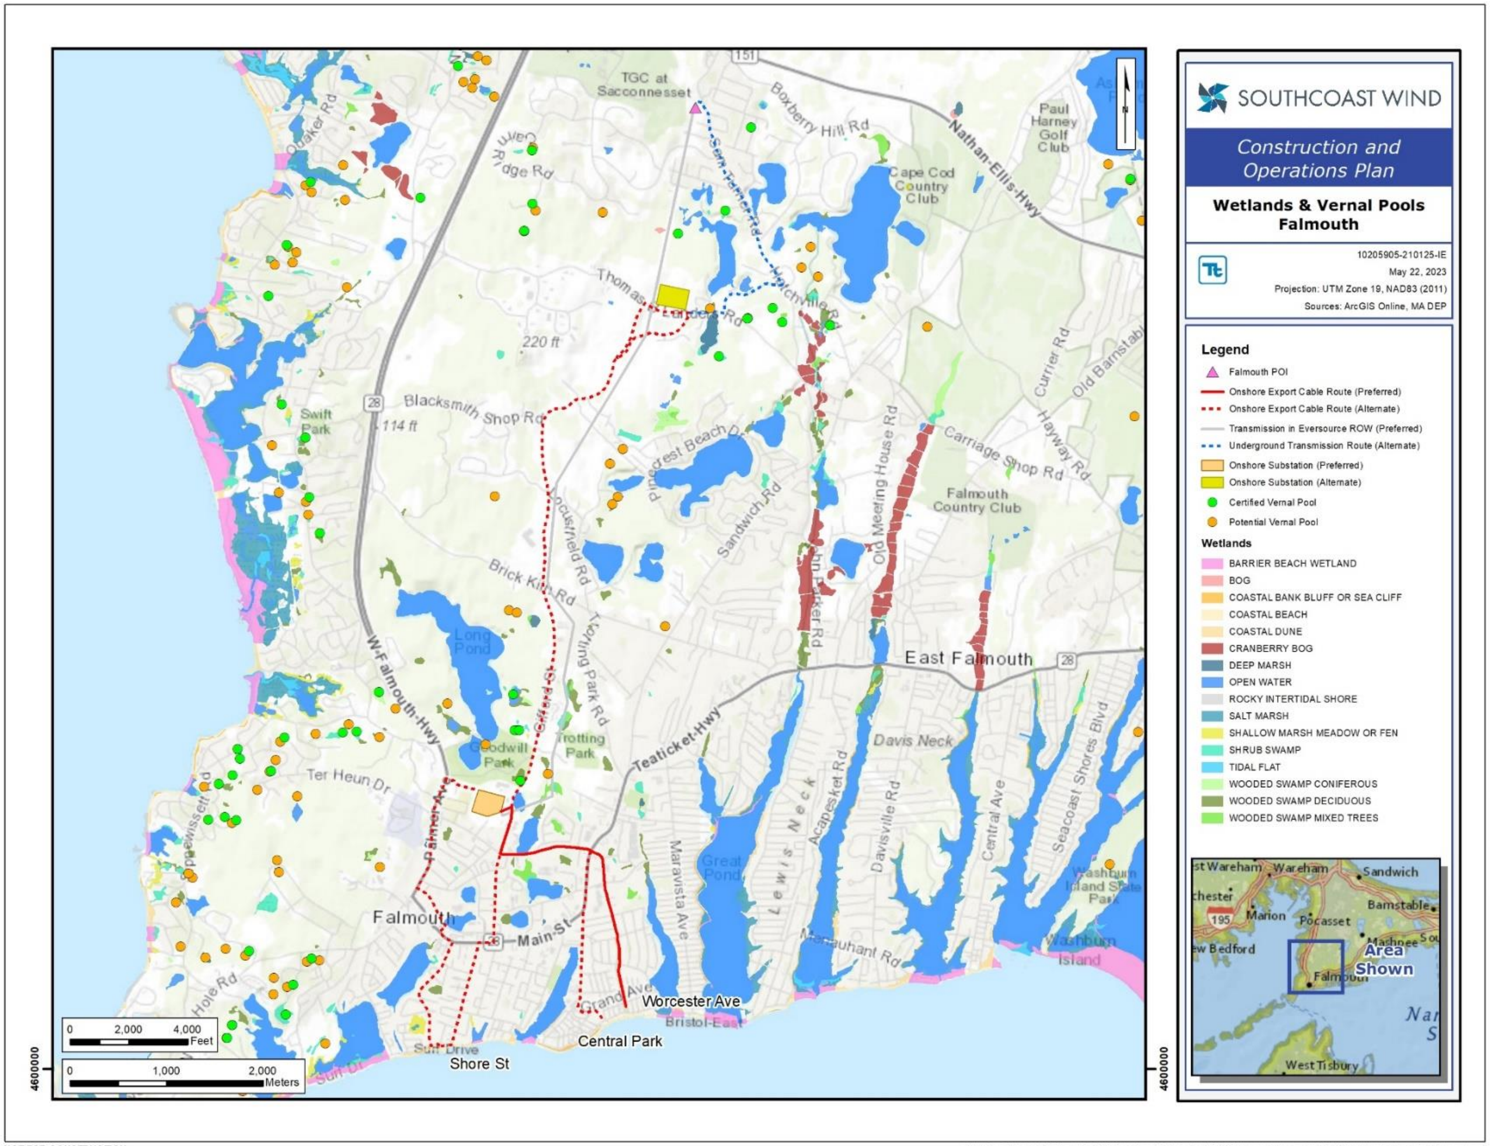

Figure F-2 Proposed Landfall Sites and Onshore Export Cables – Falmouth Variant

F.1 Falmouth Variant Alternatives (see Table F-1 for quantitative summary)

Proposed Action Offshore Export Cable Route

The Proposed Action Offshore Export Cable Route would run from the Lease Area in federal waters through Muskeget Channel and into Nantucket Sound in Massachusetts state waters, to make landfall in Falmouth, Massachusetts.

This route would be 137,442 linear feet of offshore cable in state waters, and there are no anticipated impacts on non-tidal waters, wetlands, or other protected resource areas anticipated (Table F-1).

Impacts to tidal waters are anticipated from horizontal directional drilling (HDD) exit pits, cable protection, and seabed preparation. Approximately 0.40 acres will be disturbed for HDD exit pits. A small portion of this route is estimated to require cable protection (Table F-1). Seabed preparation includes boulder field clearance where necessary, utilizing a boulder plow as well as local boulder removal via boulder grabs in other locations (Table F-1). Boulder field clearance is expected to be needed primarily in areas of this route traversing Muskeget Channel and Nantucket Sound.

The Proposed Action Offshore Export Cable Route follows the westernmost route option through Muskeget Channel. The western route has fewer areas of high risk related to extremely shallow water depths than the other options. The western route avoids ultra-shallow sections of the Muskeget Channel that would pose significant navigational hazards (even to a shallow-draft cable lay barge) during cable installation and (if needed) repair. It has a greater length proximate to or co-located with the Vineyard Wind 1 cables, which may reduce the cumulative impact area of both projects.

Proposed Alternative Offshore Export Cable Route 1

Falmouth Proposed Alternative Offshore Cable Route 1 would run from the Lease Area in federal waters through Muskeget Channel and into Nantucket Sound in Massachusetts state waters, to make landfall in Falmouth, Massachusetts. Proposed Alternative Offshore Cable Route 1 runs just east of the proposed offshore export cable route and is the easternmost option of the alternatives down-selected through Muskeget Channel.

This route would be 134,515 linear feet of offshore cable in state waters, and there are no impacts on non-tidal waters, wetlands, or other protected resource areas anticipated (Table F-1).

Impacts to tidal waters are anticipated from HDD exit pits, cable protection, and seabed preparation. Approximately 0.40 acres will be disturbed for HDD exit pits. A small portion of this route is estimated to require cable protection (Table F-1). Seabed preparation includes boulder field clearance where necessary, utilizing a boulder plow as well as local boulder removal via boulder grabs in other locations (Table F-1). Boulder field clearance is expected to be needed primarily in areas of this route traversing Muskeget Channel and Nantucket Sound.

SouthCoast Wind deselected Falmouth Proposed Alternative Offshore Cable Route 1 as it was deemed redundant due to its similarity to the Proposed Action Offshore Export Cable Route through Muskeget Channel and into Nantucket Sound.

Proposed Alternative Offshore Export Cable Route 2

Falmouth Proposed Alternative Offshore Cable Route 2 would run from the Lease Area in federal waters through Muskeget Channel and into Nantucket Sound in Massachusetts state waters, to make landfall in Falmouth, Massachusetts. Proposed Alternative Cable Route 2 follows the same route as Proposed Alternative Offshore Cable Route 1; however, it diverts to the east and reconnects to Alternative 3 (discussed below).

This route would be 147,259 linear feet of offshore cable in state waters and would utilize HDD for the sea-to-shore transition of export cables between the ocean and the land; therefore, there are no impacts to non-tidal waters, wetlands, or other protected resource areas anticipated (Table F-1).

Impacts to tidal waters are anticipated from HDD exit pits, cable protection, and seabed preparation. Approximately 0.40 acres will be disturbed for HDD exit pits. A small portion of this route is estimated to require cable protection (Table F-1). Seabed preparation includes boulder field clearance where necessary, utilizing a boulder plow as well as local boulder removal via boulder grabs in other locations (Table F-1). Boulder field clearance is expected to be needed primarily in areas of this route traversing Muskeget Channel and Nantucket Sound.

SouthCoast Wind deselected Falmouth Proposed Alternative Offshore Cable Route 2 to avoid overlap with other proposed offshore wind projects and because of challenging seabed conditions within Muskeget Channel, including expected high sediment mobility, very shallow bathymetry, and high seabed slopes, that were identified during reconnaissance and site characterization surveys completed in 2020. The resulting level of technical risk was too high to carry these corridors through for the Project Design Envelope (PDE).

Proposed Alternative Offshore Export Cable Route 3

Falmouth Proposed Alternative Offshore Cable Route 3 would run from the Lease Area in federal waters through Muskeget Channel and into Nantucket Sound in Massachusetts state waters, to make landfall in Falmouth, Massachusetts. Proposed Alternative Offshore Cable Route 3 is farther east compared to the proposed alternative and turns left parallel to the northernmost part of Martha's Vineyard.

This route would be 113,989 linear feet of offshore cable in state waters, and there are no impacts on non-tidal waters, wetlands, or other protected resource areas anticipated (Table F-1).

Impacts to tidal waters are anticipated from HDD exit pits, cable protection, and seabed preparation. Approximately 0.40 acres will be disturbed for HDD exit pits. A small portion of this route is estimated to require cable protection (Table F-1). Seabed preparation includes boulder field clearance where necessary, utilizing a boulder plow as well as local boulder removal via boulder grabs in other locations (Table F-1). Boulder field clearance is expected to be needed primarily in areas of this route traversing Muskeget Channel and Nantucket Sound.

SouthCoast Wind deselected Falmouth Proposed Alternative Offshore Cable Route 3 to avoid overlap with other proposed offshore wind projects and because of challenging seabed conditions, including expected high sediment mobility, very shallow bathymetry, and high seabed slopes within Muskeget Channel that were identified during reconnaissance and site characterization surveys completed in 2020. The resulting level of technical risk was too high to carry these corridors through for the PDE.

Proposed Alternative Offshore Export Cable Route 4

Falmouth Proposed Alternative Offshore Cable Route 4 would run from the Lease Area in federal waters through Muskeget Channel and into Nantucket Sound in Massachusetts state waters, to make landfall in Falmouth, Massachusetts. Alternative 4 is the easternmost cable route, closest to Nantucket, that heads to the east then curves west to rejoin the Alternative Offshore Cable Route 3 proposed corridor.

This route would be 119,779 linear feet of offshore cable in state waters, and there are no impacts on non-tidal waters, wetlands, or other protected resource areas anticipated (Table F-1).

Impacts to tidal waters are anticipated from HDD exit pits, cable protection, and seabed preparation. Approximately 0.40 acres will be disturbed for HDD exit pits. A small portion of this route is estimated to require cable protection (Table F-1). Seabed preparation includes boulder field clearance where necessary utilizing a boulder plow, as well as local boulder removal via boulder grabs in other locations (Table F-1). Boulder field clearance is expected to be needed primarily in areas of this route traversing Muskeget Channel and Nantucket Sound.

SouthCoast Wind deselected Falmouth Proposed Alternative Offshore Cable 4 because of challenging seabed conditions that were identified in a desktop assessment, amounting to a high level of technical risk, especially near Muskeget Island and Nantucket. For Falmouth Proposed Alternative Offshore Cable Routes 2 through 4, these challenging seabed conditions include expected high sediment mobility, very shallow bathymetry, and high seabed slopes.

Worcester Ave Landing to Proposed Onshore Substation Alternative

The proposed landfall is the easternmost potential landfall site located at Worcester Avenue. This location is protected by a short seawall, a broad beach, and Surf Drive. This landfall site would be located on a previously disturbed, off-road grassy median strip (also known as Worcester Park) that runs between the two lanes of Worcester Avenue. Residences and a hotel are adjacent to this landfall site but are buffered from the open green space by Worcester Avenue on either side. A paved parking lot located nearby could be used for construction staging operations. There are no known existing submarine cables that make landfall at Worcester Avenue and this landfall would avoid the need to cross any existing submarine cables between Martha's Vineyard and Falmouth, Massachusetts.

There are no anticipated impacts on non-tidal waters, wetlands, or other special aquatic sites. This location is within northern long-eared bat habitat range, but due to no tree clearing, impacts are not anticipated. See Table F-1 for an impact summary.

The Worcester Avenue landfall is the Proposed Action because it has the overall shortest length to the substation and minimal impacts on protected resources. The Worcester Avenue landfall is 2.0 miles (3.3 kilometers) from the proposed Onshore Substation located at Lawrence Lynch and 5.9 miles (9.4 kilometers) from the alternate Onshore Substation located at Cape Cod Aggregates.

Central Park Landing to the Proposed Onshore Substation Alternative

The Central Park landing is approximately 700 feet (213 meters) west of the Worcester Avenue landfall location, situated at Central Park on Falmouth Heights Beach north of Grand Avenue. This landfall site is proposed, yet not preferred, by SouthCoast Wind, and would occur at a public recreational park with a baseball diamond and basketball court. The park is flanked on the southern side by paved parking spaces, which could be used for construction staging operations. There are no known existing submarine cables that make landfall at Central Park and this landfall would avoid the need to cross any existing submarine cables between Martha's Vineyard and Falmouth, Massachusetts.

The Central Park landing and onshore cable route to the substation would have no impacts on non-tidal waters, wetlands, or other special aquatic sites (Table F-1). This location is within northern long-eared bat habitat range, but due to no tree clearing, impacts are not anticipated.

The Central Park landing and cable route to the substation is not preferred by SouthCoast Wind, due to its longer length and potential interference with activities at Central Park. The Central Park landfall is 2.2 miles (3.5 kilometers) from the proposed Onshore Substation located at Lawrence Lynch and 6.1 miles (9.8 kilometers) from the alternate Onshore Substation located at Cape Cod Aggregates.

Shore Street Landing to Proposed Onshore Substation Alternative

The Shore Street landfall site is west of the Central Park and Worcester Avenue landfall sites. This landfall site is proposed, yet not preferred, by SouthCoast Wind that is located on Surf Drive Beach at the intersection of Surf Drive and Shore Street. An existing seawall and nearby rock jetties protect this landfall site. The Shore Street location has a large, over 2 acres (0.8 hectare) public parking lot that could be used to site the cable transition joint bays and accommodate vehicles and equipment during installation operations. The Shore Street landfall location involves the potential crossing of two existing submarine cables that also make landfall at Shore Street. The existing arrangement may allow SouthCoast Wind to HDD underneath the existing cables in the approach to the landfall location.

SouthCoast Wind will utilize HDD for the sea-to-shore transition of export cables between the ocean and the land. Due to HDD drilling activities, there is 0.26 acre of anticipated temporary wetland impact. There is 0.01 acre of potential impacts on non-tidal waters due to a small stream crossing. This stream will be crossed by running over or under the existing culvert and would not result in permanent impacts. There are no anticipated impacts on other special aquatic sites. This location is within northern long-eared bat habitat range, but due to no tree clearing, impacts are not anticipated. See Table F-1 for an impact summary.

The Shore Street landing and cable route to the onshore alternate substation is not preferred due to its potential to cross existing submarine cables, and also due to its length. The Shore Street landfall is 2.3 miles (3.6 kilometers) from the proposed Onshore Substation located at Lawrence Lynch and 6.4 miles (10.25 kilometers) from the proposed alternative Onshore Substation located at Cape Cod Aggregates.

Table F-1. Clean Water Act Section 404(b)(1) alternatives analysis table – Falmouth

[a] Excludes onshore export cable segments (i.e., export cable segments landward of the landfall).
[b] Distances reported in linear feet are inclusive of all export cable circuits.
[c] These numbers were achieved assuming the PDE max of 3-meter cable burial depth and 1-meter wide corridor. This is representative of one cable. The Falmouth export cable corridor will contain up to five cables. Anticipated cable burial depth for the construction of the Project is 1.2 meters.
[d] Within northern long-eared bat habitat range; impacts on northern long-eared bat habitat are not anticipated.

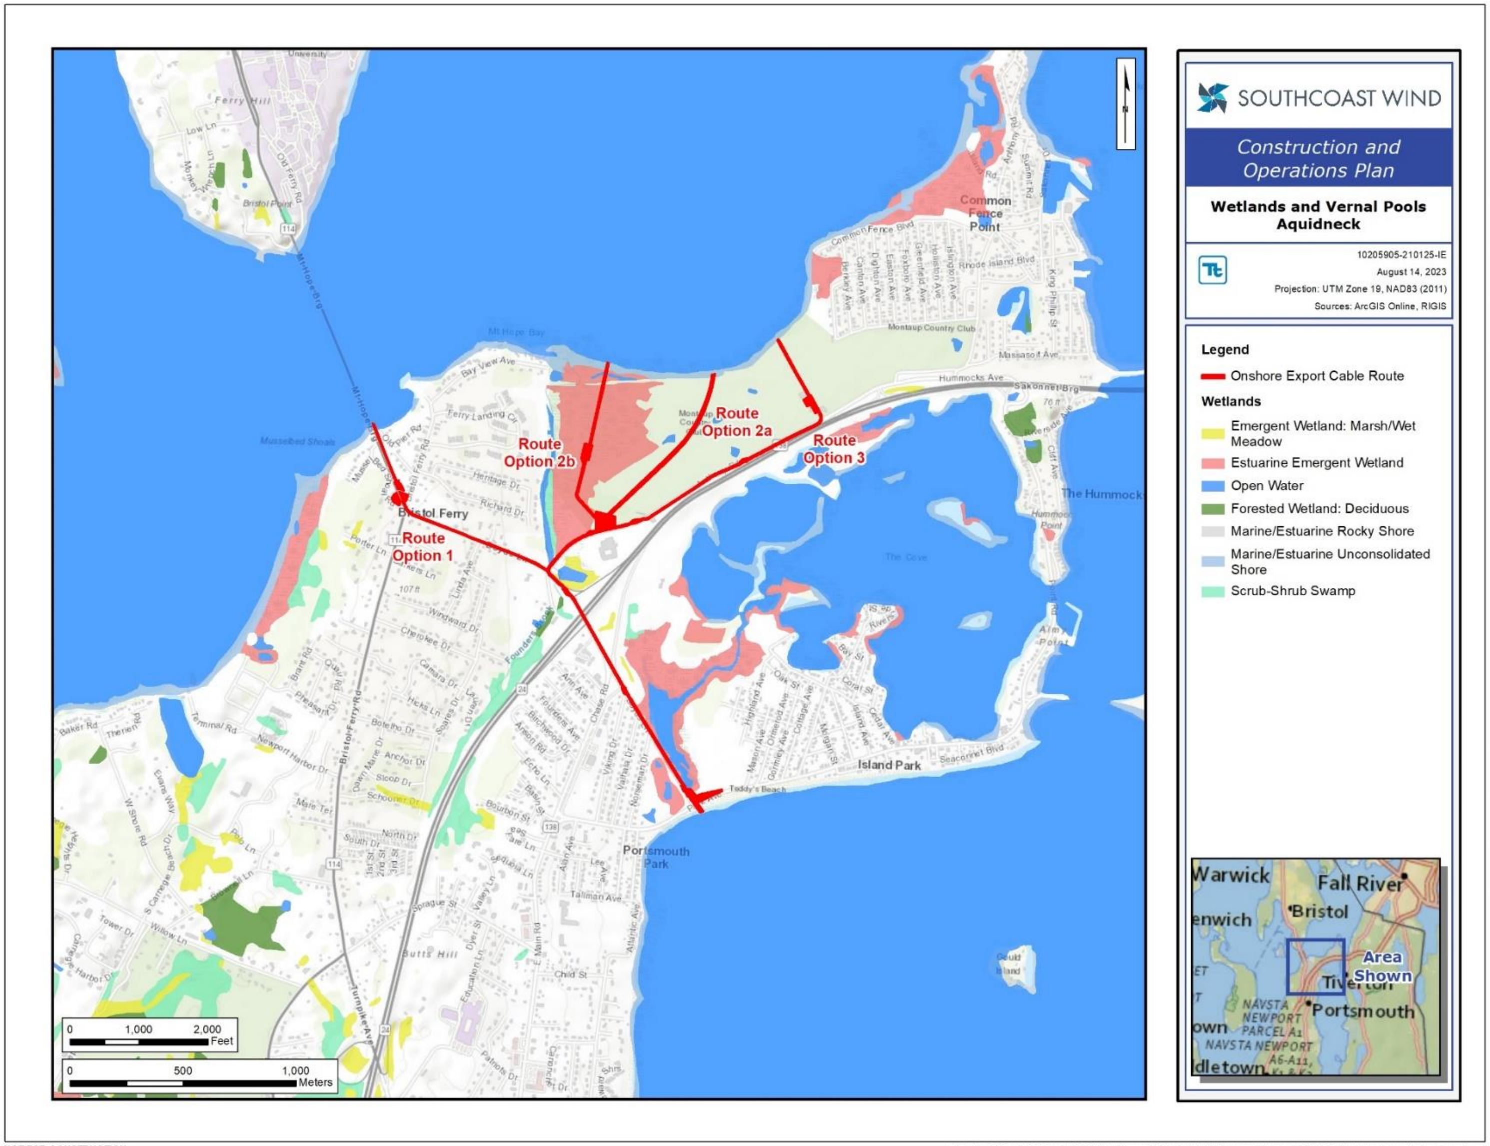

Figure F-3 Proposed Landfall Sites and Onshore Export Cables – Aquidneck Island

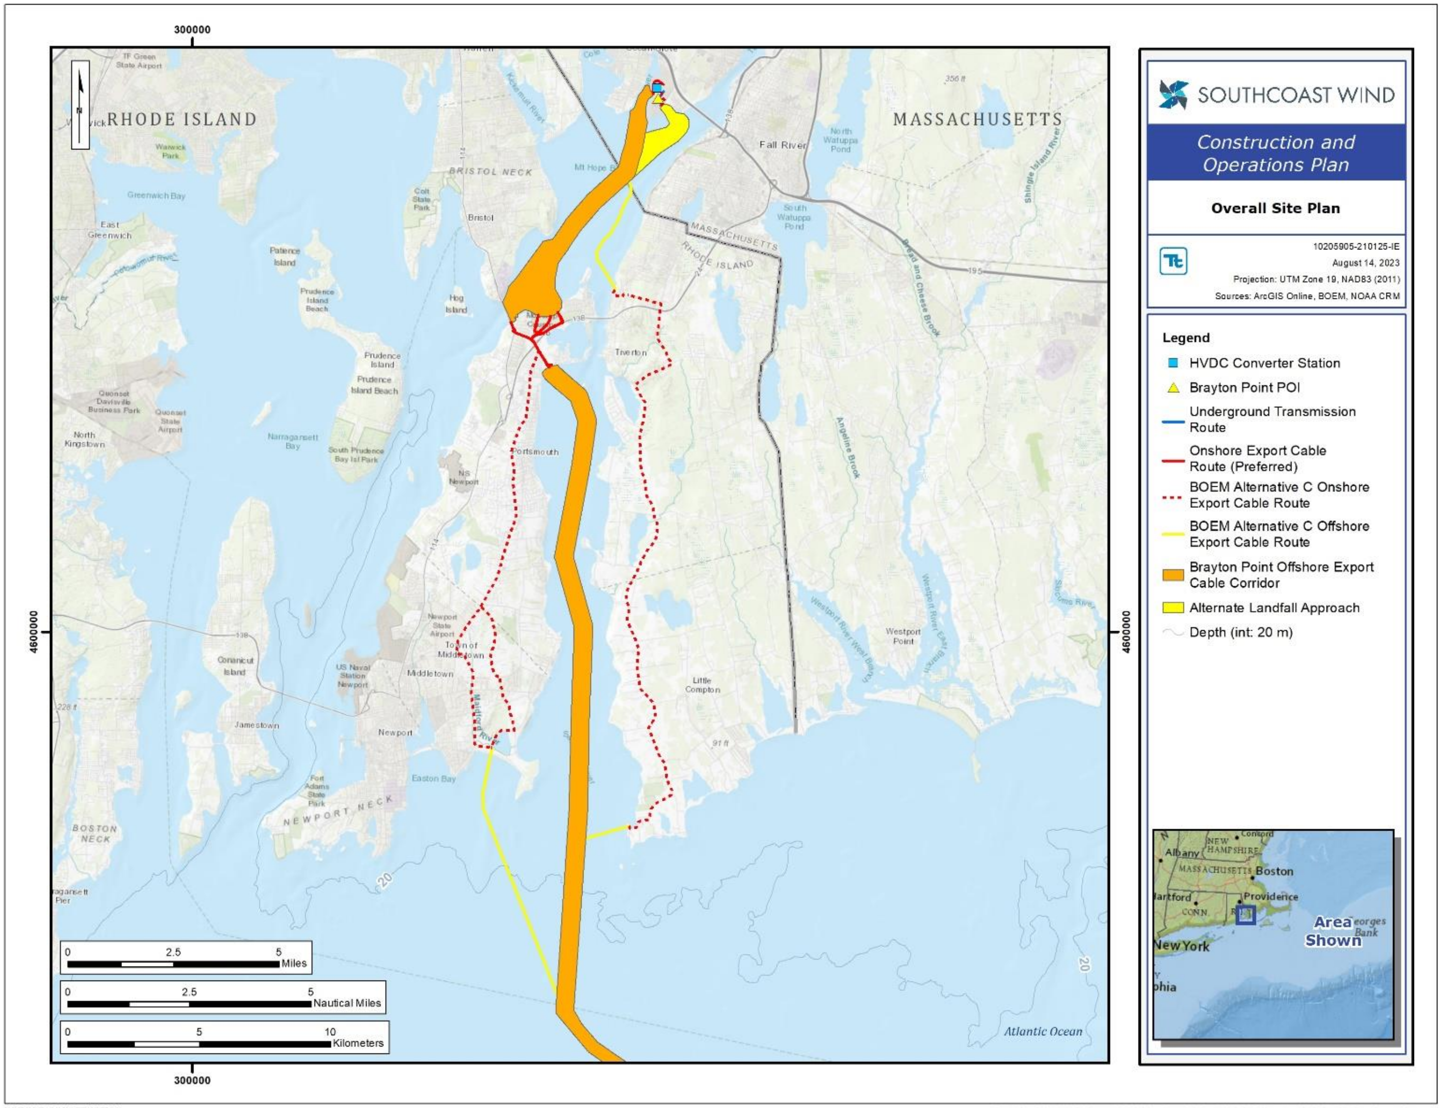

NOT FOR CONSTRUCTION

Figure F-4 BOEM Alternative Landfall Sites and Onshore Export Cables – Brayton Point (inclusive of BOEM Alternative C-1 and Alternative C-2 routes)

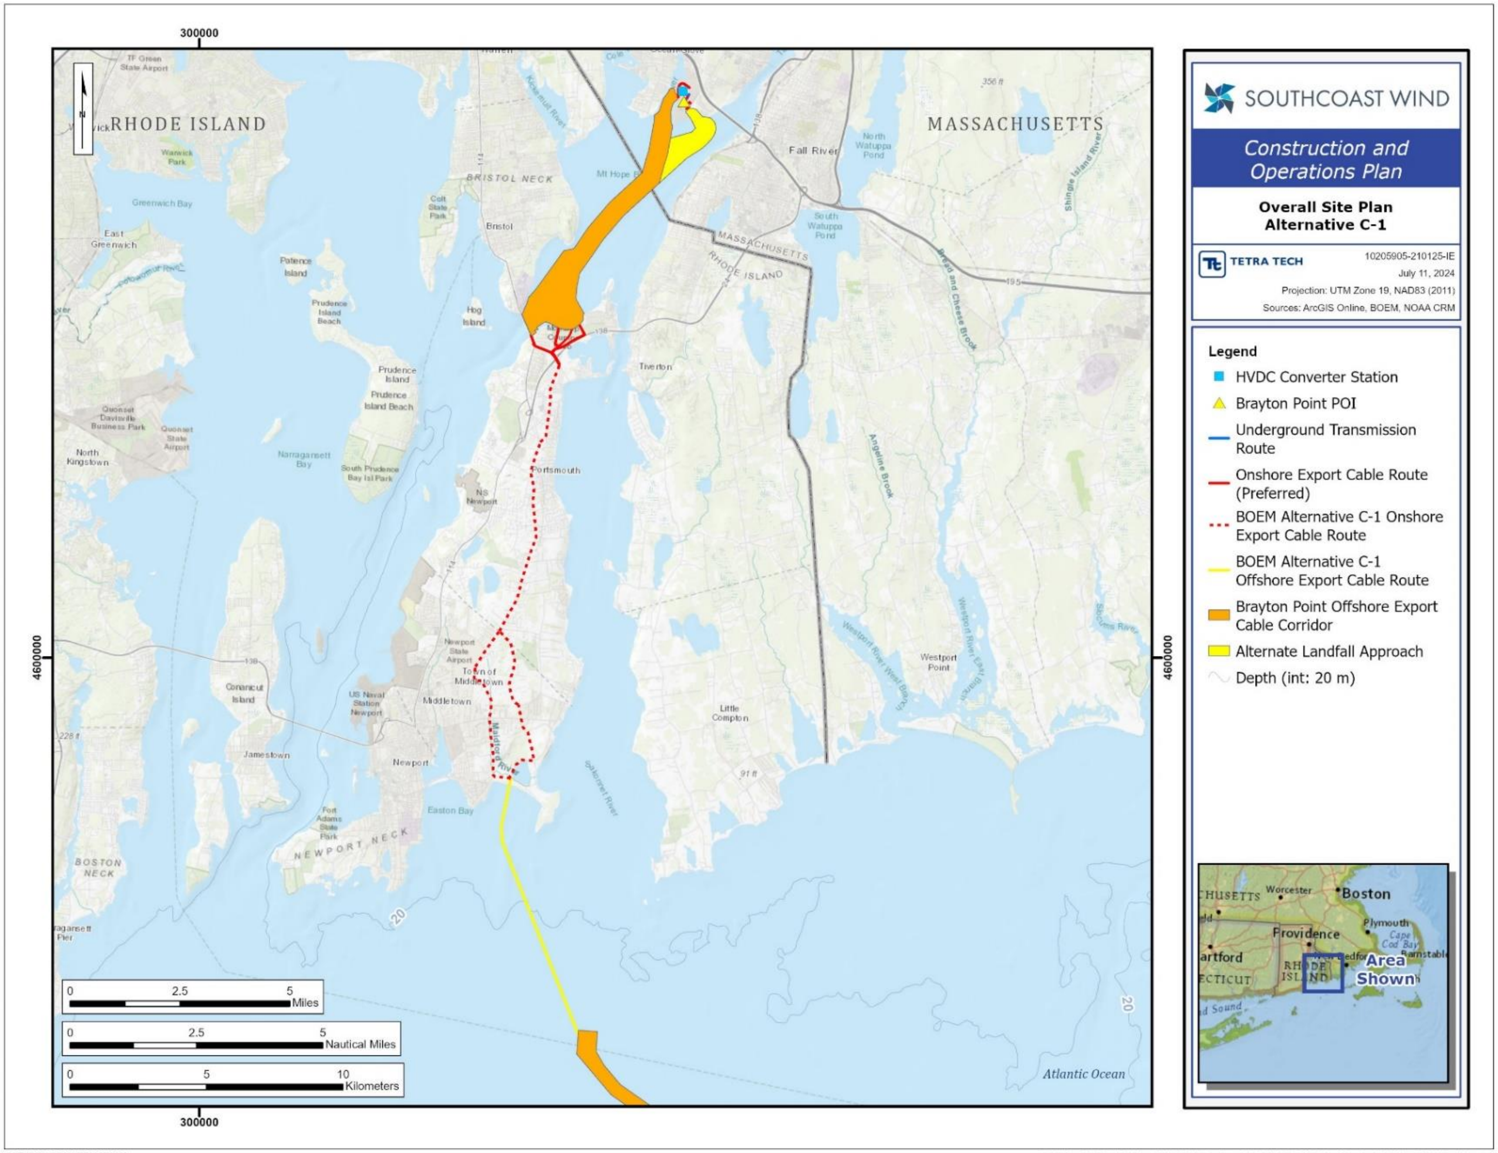

Figure F-5 BOEM Alternative C-1 Route (Eastern and Western)

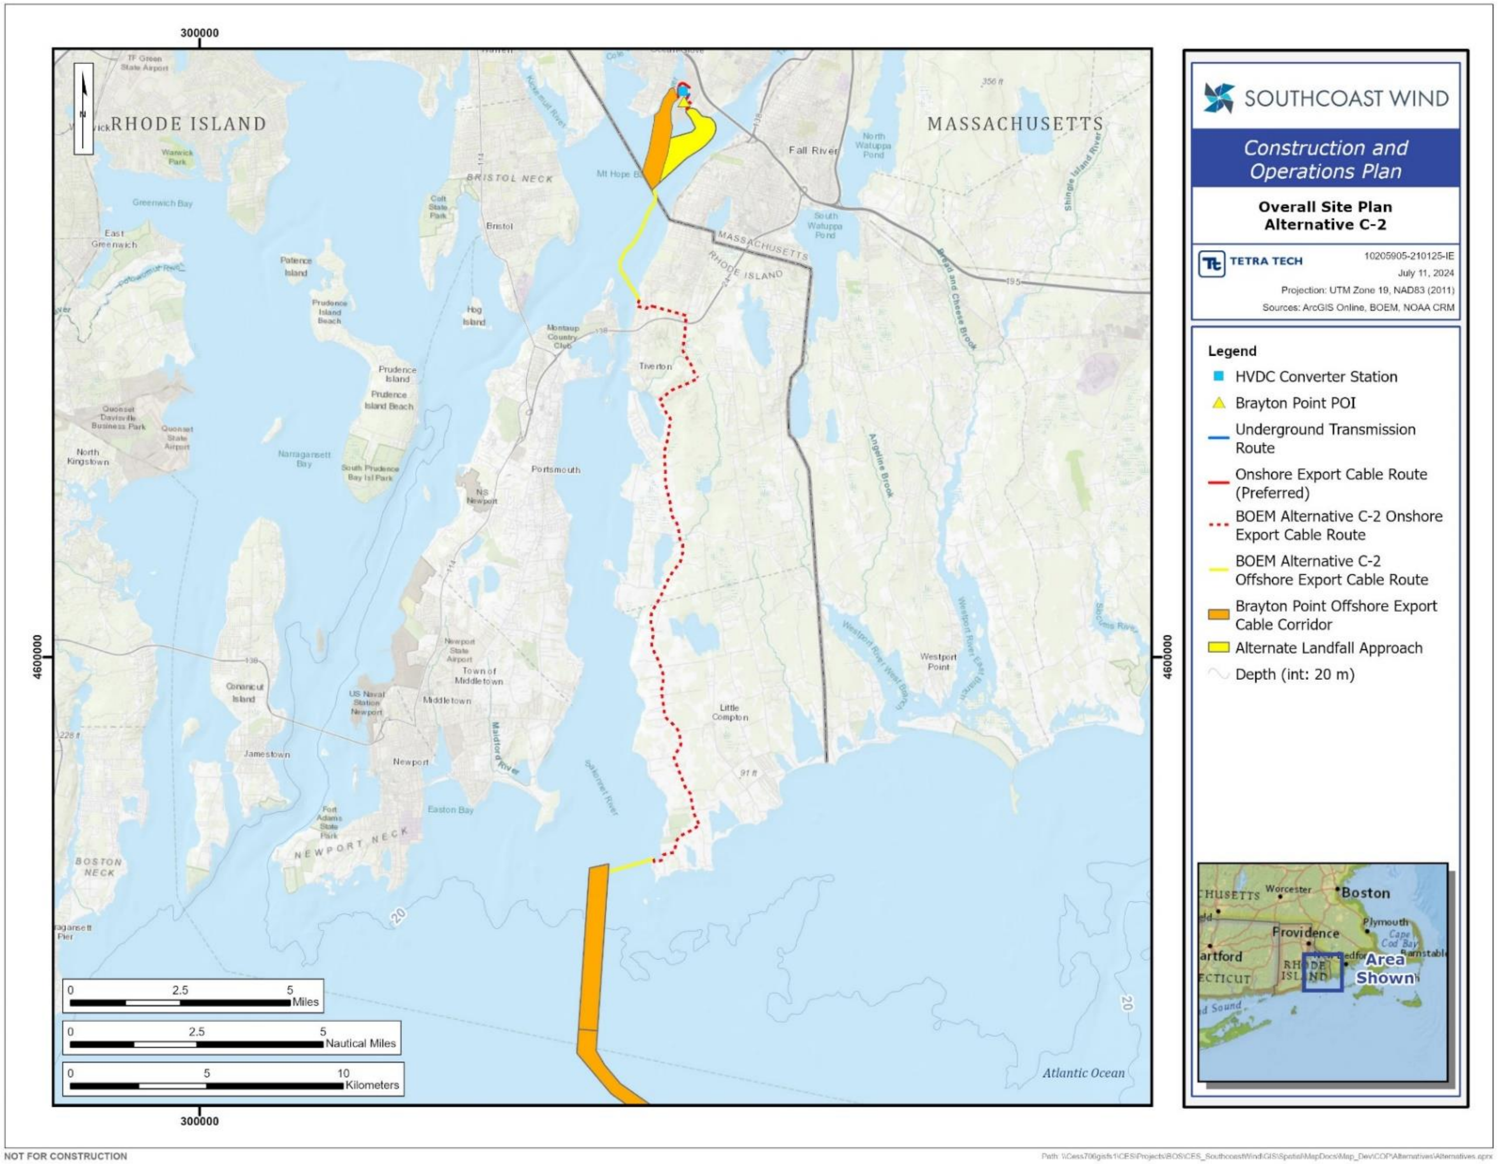

Figure F-6 BOEM Alternative C-2 Route

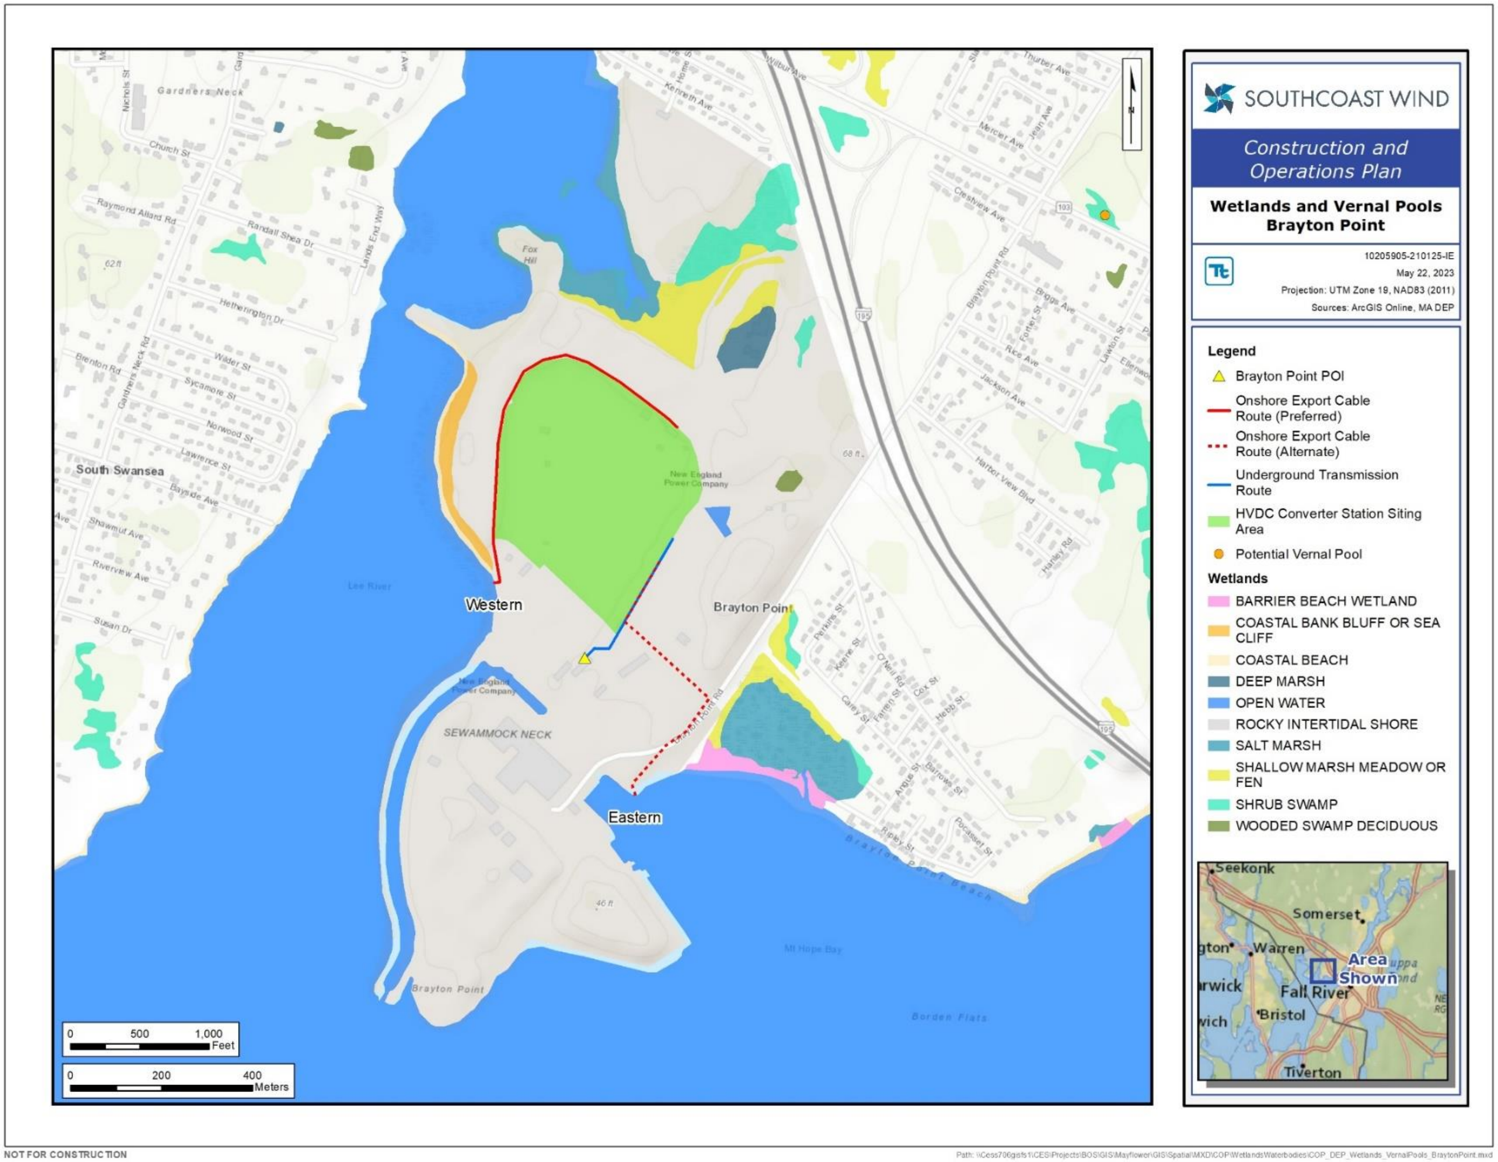

Figure F-7 Proposed Landfall Sites and Onshore Export Cables – Brayton Point

F.2 Brayton Point (see Table F-2 – Table A and B for quantitative summary)

Proposed Action over Aquidneck Island via the Lee River (Western Route) or via the Taunton River (Eastern Route) with Point of Interconnection at Brayton Point, with Portsmouth Route Options 1, 2A, 2B, and 3 (Figure F-1)

The Proposed route alternative over Aquidneck Island would traverse north from the Lease Area up the Sakonnet River. The offshore export cables would come ashore from the Sakonnet River to Portsmouth, Rhode Island at the northeast corner of Boyds Lane and Park Avenue. Landfall would be accomplished using HDD technology to drill below the beach, seawall, and Park Avenue. This selected alternative includes an intermediate, onshore underground crossing of Aquidneck Island, through Portsmouth (route options and impacts described in further detail below), continuing offshore through Mount Hope Bay. The cables would then travel northwest through Mount Hope Bay to Brayton Point via the Lee River and would connect to the point of interconnection (POI) at Brayton Point in Somerset, Massachusetts.

Approximately 2.0 miles (3.4 kilometers) of onshore, underground export cable would be routed north through Portsmouth from the intersection of Boyds Lane and Park Avenue on the east side of Boyds Lane. From here, four onshore route variants are being considered:

- Route Option 1 (121,065.7 total linear feet of offshore cable in state waters): Route Option 1 would continue north on Boyds Lane to the area around the Mount Hope Bridge access ramps, with HDD conducted on the east side of the Mount Hope Bridge into Mount Hope Bay. Because the route uses HDD for the sea-to-shore transitions, there are no impacts on tidal waters, or other protected resource areas anticipated (Table F-2). Due to a stream crossing with a culvert along the route, there are 0.04 acres of temporary impacts on non-tidal waters anticipated (Table F-2). Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.012 acres of temporary wetlands impacts anticipated due to construction activities.

- Route Option 2B (118,991.3 linear feet of offshore cable in state waters): Route Option 2B would continue east onto Anthony Road, turning north onto RIDEM/Aquidneck Land Trust, with HDD conducted in a northeasterly direction. Because the route uses HDD for sea-to-shore transitions, there are no impacts on tidal waters, or other protected resource areas anticipated. Due to multiple stream crossings with culverts along the route, there are 0.08 acres of temporary impacts on non-tidal waters anticipated (Table F-2). Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.012 acres of temporary wetlands impacts anticipated due to construction activities. There are no other anticipated impacts on protected resources. See Table F-2 for an impact summary.

- Route Option 2A (119,075.5 linear feet of offshore cable in state waters): Route Option 2A would continue east onto Anthony Road and onto Roger Williams University property, with HDD conducted in a northeasterly direction toward Mount Hope Bay. Because the route uses HDD for the sea-to-shore transitions, there are no impacts on tidal waters, or other protected resource areas anticipated. Due to multiple stream crossings with culverts along the route, there are 0.08 acres of temporary impacts on non-tidal waters anticipated (Table F-2). Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.012 acres of temporary wetlands impacts anticipated due to construction activities. There are no other anticipated impacts on protected resources. See Table F-2 for an impact summary.

- Route Option 3 (118,945.2 linear feet of offshore cable in state waters): Route Option 3 would continue east onto Anthony Road to the entrance of Montaup Country Club, with HDD headed northwest to Mount Hope Bay conducted from the Montaup Country Club parking area. Because the route uses HDD for the sea-to-shore transitions, there are no impacts on tidal waters, or other protected resource areas anticipated. Due to multiple stream crossings with culverts along the route, there are 0.08 acres of temporary impacts on non-tidal waters anticipated (Table F-2). Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.012 acres of temporary wetlands impacts anticipated due to construction activities. There are no other anticipated impacts on protected resources. See Table F-2 for an impact summary.

After the onshore route over Aquidneck Island, the Proposed Action would then make landfall at Brayton Point via the Lee River (Western Route) or the Taunton River (Eastern Route). The Western Route is the preferred route alternative.

SouthCoast Wind chose the Western Route as the preferred route alternative over Aquidneck Island via the Lee River because it has a shorter, more direct route length relative to the other routes and avoids or minimizes potential conflicts with other marine stakeholders including recreational vessel users, federally maintained shipping channel (USACE Fall River Harbor Federal Navigation Project), protected wildlife areas, and the U.S. Naval Station (NAVSTA) Newport facility which encompasses approximately 1,000 acres on the west shore of Aquidneck Island, facing the east passage of Narragansett Bay, located in the towns of Portsmouth, Middletown, and Newport, Rhode Island. The alternative route with the eastern landfall via the Taunton River is the alternate to the preferred route due to a slightly longer route length. This alternative route avoids or minimizes potential conflicts with other marine stakeholders including recreational vessel users, federally maintained shipping channels, protected wildlife areas, and the U.S. Navy.

Fisheries Habitat Impact Minimization Alternative C1 Western (Middletown/ Paradise Ave) with Point of Interconnection at Brayton Point with Portsmouth Route Options 1, 2A, 2B, and 3 (Figure F-5)

Fisheries Habitat Impact Minimization Alternative C1 Western would make landfall at the parking lot for Second Beach in Middletown via HDD under the municipal public beach from Sachuest Bay. From the landfall, the approximately 11-mile (17.7-kilometer) onshore route would proceed inland through Middletown via Paradise Avenue and Route 138, crossing into Portsmouth to join Route Options 1, 2A, 2B, and 3 discussed above and continuing offshore through Mount Hope Bay. The cables would then travel northwest through Mount Hope Bay to Brayton Point via the Lee River (Western Route) or the Taunton River (Eastern Route) and would connect to the POI at Brayton Point in Somerset, Massachusetts.

Route Options 1, 2A, 2B and 3 are discussed in further detail below:

- Route Option 1 (72,860 total linear feet of offshore cable in state waters): Route Option 1 would continue north on Boyds Lane to the area around the Mount Hope Bridge access ramps, with HDD conducted on the east side of the Mount Hope Bridge into Mount Hope Bay. Due to HDD construction, there are no anticipated impacts on tidal waters. There are 0.18 acres of temporary impacts anticipated to non-tidal waters due to a stream crossing along the route. Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.497 acres of temporary wetlands impacts anticipated due to construction activities. There would be no impacts on eelgrass or mudflats. See Table F-2 for an impact summary.
- Route Option 2B (72,399 linear feet of offshore cable in state waters): Route Option 2B would continue east onto Anthony Road, turning north onto RIDEM/Aquidneck Land Trust, with HDD conducted in a northeasterly direction. Due to HDD construction, there are no anticipated impacts on tidal waters. There are 0.22 acres of temporary impacts anticipated to non-tidal waters due to a stream crossing along the route. Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.497 acres of temporary wetlands impacts anticipated due to construction activities. There would be no impacts on eelgrass or mudflats. See Table F-2 for an impact summary.
- Route Option 2A (70,876.6 linear feet of offshore cable in state waters): Route Option 2A would continue east onto Anthony Road and onto Roger Williams University property, with HDD conducted in a northeasterly direction toward Mount Hope Bay. There are 0.22 acres of temporary impacts anticipated to non-tidal waters due to a stream crossing along the route. Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.497 acres of anticipated impact on wetlands due to construction activities. There would be no impacts on eelgrass or mudflats. See Table F-2 for an impact summary.
- Route Option 3 (70,746 linear feet of offshore cable in state waters): Route Option 3 would continue east onto Anthony Road to the entrance of Montaup Country Club, with HDD headed northwest to Mount Hope Bay conducted from the Montaup Country Club parking area. Due to HDD construction, there are no anticipated impacts on tidal waters. There are 0.22 acres of temporary impacts anticipated to non-tidal waters due to a stream crossing along the route. Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.497 acres of temporary wetlands impacts anticipated due to construction activities. There would be no impacts on eelgrass or mudflats. See Table F-2 for an impact summary.

The additional length and impacts on sensitive environmental resources and historic resources are greater, as compared to the Proposed Action. Second Beach, where this alternative would make landfall, is a dynamic beach system with mobile sediments, surrounded by wetlands, parks, and natural heritage. The Second Beach landfall site and routing also abuts the Norman Bird Sanctuary, a 325-acre bird sanctuary, nature preserve, environmental education center, and museum. To the west is Newport, a popular, year-round tourist destination and a designated Rhode Island historic district. In addition, this route passes through multiple residential areas, and also through High Value/High Vulnerability Habitat[1] and Natural Heritage Areas. Paradise School, a historic property, is located along the route. There are also ten National Register-eligible resources within 0.5 mile of the route along with ten archaeological sites along the route.

Fisheries Habitat Impact Minimization Alternative C1 Eastern (Middletown/ Mitchell's Lane) with Point of Interconnection at Brayton Point with Portsmouth Route Options 1, 2A, 2B, and 3 (Figure F-5)

Fisheries Habitat Impact Minimization Alternative C1 Eastern would make landfall at the parking lot for Second Beach in Middletown via HDD under the municipal public beach from Sachuest Bay, similar to Fisheries Habitat Impact Minimization Alternative C1 Western. From the landfall, the approximately 11-mile (17.7-kilometer) onshore route would head east along Hanging Rock Road, then travel via Mitchell's Lane to Route 138, crossing into Portsmouth to join Route Options 1, 2A, 2B, and 3 discussed above and continuing offshore through Mount Hope Bay. The cables would then travel northwest through Mount Hope Bay to Brayton Point via the Lee River (Western Route) or the Taunton River (Eastern Route) and would connect to the POI at Brayton Point in Somerset, Massachusetts. Alternative C1 Eastern would also pass through several protected resource areas, including Normans Bird Sanctuary and the Sachuest Point National Wildlife Refuge.

Route Options 1, 2A, 2B, and 3 are discussed in further detail below:

- Route Option 1 (74,026 total linear feet of offshore cable in state waters): Route Option 1 would continue north on Boyds Lane to the area around the Mount Hope Bridge access ramps, with HDD conducted on the east side of the Mount Hope Bridge into Mount Hope Bay. Due to HDD construction, there are no anticipated impacts on tidal waters. There are 0.13 acres of temporary impact anticipated to non-tidal waters due to a stream crossing along the route. Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.492 acres of temporary wetlands impacts anticipated due to construction activities. There are no anticipated impacts on eelgrass or mudflats. See Table F-2 for an impact summary.

- Route Option 2B (71,785 linear feet of offshore cable in state waters): Route Option 2B would continue east onto Anthony Road, turning north onto RIDEM/Aquidneck Land Trust, with HDD conducted in a northeasterly direction. Due to HDD construction, there are no anticipated impacts on tidal waters. There are 0.17 acres of temporary impacts anticipated to non-tidal waters due to a stream crossing along the route. Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.492 acres of temporary wetlands impacts anticipated due to

[1] Categorized by Rhode Island Department of Environmental Management by the following: Includes flood plain forest, hemlock/hardwood forest, northern hardwood forest, pitch pine/barrens, mud flat, inland sand barren, salt marsh, wet meadow, coastal streams, tidal marsh, rocky shore, sand flat, sea level fen, brackish sub-aquatic beds, brackish marsh, and Atlantic white cedar swamp.

construction activities. There are no anticipated impacts on eelgrass or mudflats. See Table F-2 for an impact summary.

- Route Option 2A (70,935 linear feet of offshore cable in state waters): Route Option 2A would continue east onto Anthony Road and onto Roger Williams University property, with HDD conducted in a northeasterly direction toward Mount Hope Bay. There are 0.17 acres of temporary impacts anticipated to non-tidal waters due to a stream crossing along the route. Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.492 acres of anticipated temporary impacts on wetlands due to construction activities. There would be no impacts on eelgrass or mudflats.

- Route Option 3 (70,808 linear feet of offshore cable in state waters): Route Option 3 would continue east onto Anthony Road to the entrance of Montaup Country Club, with HDD headed northwest to Mount Hope Bay conducted from the Montaup Country Club parking area. Due to HDD construction, there are no anticipated impacts on tidal waters. There are 0.17 acres of temporary impacts anticipated to non-tidal waters due to a stream crossing along the route. Streams will be crossed by installing the cable either over or under the existing culvert. There are 0.492 acres of temporary wetlands impacts anticipated due to construction activities. There would be no impacts on eelgrass or mudflats. See Table F-2 for an impact summary.

The additional length and potential impacts on sensitive environmental resources are greater, as compared to the Proposed Action. This onshore route passes through multiple residential areas, and also through High Value/High Vulnerability Habitat and Natural Heritage Areas 237, 216, and 209 according to RIDEM and RIGIS mapping. This route also passes Gardiner Pond, a City of Newport drinking water supply area, and Paradise Brook. Historic properties along the route include Gardiner Pond Shell Midden and Union Church and Southernmost Schoolhouse. Additional sensitive receptors abut this alternative including wetlands, parks, reserves, emergency and rescue services facilities, schools, and government facilities.

Fisheries Habitat Impact Minimization Alternative C2 with Point of Interconnection at Brayton Point (Figure F-6)

Fisheries Habitat Impact Minimization Route C2 would make intermediate landfall at Sakonnet Point in Little Compton in a 0.9-acre parking lot across from the Sakonnet Harbor. The 15.8-mile (25.4-kilometer) route would then head east and turns north, following Route 77 along the Sakonnet River coast through Little Compton and into Tiverton. Once in Tiverton, the route turns east onto Route 177. The route heads north on Fish Road and then turns northwest on Souza Road. Souza Road turns into Schooner Drive, which is a steep access road to the dense residential Village at Mount Hope Bay and Boat House Waterfront Dining Restaurant. The route then re-enters the water from private property near where Mount Hope Bay and the Sakonnet River meet, north of the State Route 24 Bridge. The export cables would then travel northwest through Mount Hope Bay to Brayton Point via the Lee River and would connect to the POI at Brayton Point in Somerset, Massachusetts. Once the export cables enter into

Mount Hope Bay from the HDD area in Tiverton, they traverse under the USACE Fall River Harbor Federal Navigation Project (FNP).

This route would be 59,621.29 linear feet of offshore cable in state waters, and because the route utilizes mostly HDD installation methodology, there are minimal expected impacts on tidal waters. There are 0.41 acres of temporary non-tidal impacts anticipated due to a stream crossing along the route. Streams will be crossed by installing the cable either over or under the existing culvert. There are also 0.12 acres of temporary wetlands impacts anticipated due to construction activities. There would be no impacts on eelgrass or mudflats. See Table F-2 for an impact summary. Alternative C2 would also pass through several protected resource areas including USACE Fall River Harbor Federal Navigation Project, the Nature Conservancy Pocasset Ridge Conservation Area, and the Audubon Emilie Ruecker Wildlife Sanctuary.

The extended duration of construction, use conflicts, potential for effects on the local economy, lack of sufficient space on small roads, and potential effects on sensitive environmental, historic, and cultural areas are greater, as compared to the Proposed Action. After landfall the route passes by a public boat ramp that construction activities would temporarily restrict access to at Sakonnet Point. It also abuts the Haffenreffer Wildlife refuge, which is a destination for birding.

Both Route 77 and Route 177 are busy two-lane roads with minimal paved shoulders that pass through a high prevalence of protected natural, historical, and agricultural areas. In Tiverton, Route 77 passes within 500 feet of Nonquit Pond and through the Tiverton Four Corners Historic District.

Before entering Mount Hope Bay, the route also travels along Schooner Drive which serves the dense residential Village at Mount Hope Bay and Boat House Waterfront Dining Restaurant. Schooner Drive is the only access route for the Boat House Waterfront Dining Restaurant and residential Village at Mount Hope Bay, meaning that construction activities would impact not only the commercial operations at the Boat House but also the residents of the Village at Mount Hope Bay, particularly if there is a road closure. Schooner Drive also includes a bridge over an abandoned railroad right-of-way, which would require a trenchless installation method.

Notes:

[a] Excludes onshore export cable segments (i.e., export cable segments landward of the landfall).

[b] Distances reported in linear feet are inclusive of all export cable circuits.

[c] A 2-meter wide by 2-meter deep corridor was used for offshore route calculations. Route calculations are representative of one cable bundle. The Brayton Point offshore export cable corridor contains up to two cable bundles.

F.3 Summary

Based on the analysis performed, SouthCoast Wind undertook a thorough route analysis and selection process for both offshore and onshore components of the Project. SouthCoast Wind identified various routes as potential alternatives to satisfy the regional need for the Project to provide renewable clean energy from offshore wind generation. SouthCoast Wind compared possible routes and route variants based upon reasonable criteria to evaluate the environmental impacts and social impacts to deliver energy from the Lease Area to the regional transmission system at Brayton Point and in Falmouth.

Brayton Point is an ideal site for the interconnection of offshore wind for several reasons, including, among others: (i) the robust 345-kilovolt regional transmission infrastructure available there, (ii) the brownfields legacy of the site, which both reduces impacts on the natural environment and provides an opportunity to revitalize it for clean energy uses and for the benefit of the community, including environmental justice populations within 1 mile of the Project location, (iii) its waterfront location, and (iv) its lack of residential abutters.

The proposed onshore substation site in Falmouth was evaluated and chosen based on land availability and proximity to potential landfall locations. Subsequently, SouthCoast Wind ruled out locations with greater environmental impacts. Sites were rejected for being too small to house all of the necessary equipment for the proposed onshore substation configuration or due to unnecessary environmental/social impacts which were apparent, such as required tree clearing, wetland and watershed resource disruption, or close proximity to residential neighborhoods.

The onshore and offshore route variants would enable SouthCoast Wind to achieve the best balance between reasonable cost and not causing unacceptable harm to the social and natural environment. Based on the foregoing analysis, SouthCoast Wind has determined the proposed routes for Brayton Point and Falmouth would result in the least impacts and would allow for safe, practical, and long-term cable installation, maintenance, and operation as compared to the alternatives considered. Construction of the Project, as proposed, will provide access to a major renewable clean energy resource, and will not cause unacceptable harm to the environment.

Appendix G: Mitigation and Monitoring

This Final Environmental Impact Statement (EIS) assesses the potential physical, biological, socioeconomic, and cultural impacts that could result from the construction, operations and maintenance (O&M), and conceptual decommissioning of the SouthCoast Wind Project (Project) proposed by SouthCoast Wind Energy LLC (SouthCoast Wind) in its Construction and Operations Plan (COP).

As part of the Project, SouthCoast Wind has committed to implement avoidance, minimization, and mitigation measures (AMMs) to avoid, reduce, mitigate, or monitor impacts on the resources discussed in Chapter 3, *Affected Environment and Environmental Consequences*, of this Final EIS. SouthCoast Wind's AMMs are part of the Proposed Action, and implementation of AMMs is considered in the impact analysis for the Proposed Action and each action alternative. These AMMs are described in Table G-1. The Bureau of Ocean Energy Management (BOEM) considers as part of the Proposed Action only those measures that SouthCoast Wind has committed to in the COP (SouthCoast Wind 2024). Attachment G-1 contains the AMMs proposed by SouthCoast Wind as part of its Request for Incidental Take Regulations application. Attachment G-2 contains the applicant-proposed Draft Post-Construction Avian and Bat Monitoring Framework. Attachment G-3 contains SouthCoast Wind's NARW Monitoring and Mitigation Plan for Pile Driving.

BOEM may select alternatives and require additional mitigation or monitoring measures to further protect and monitor these resources. Additional mitigation and monitoring measures, shown in Table G-2, may result from reviews under several environmental statutes (Clean Air Act, Endangered Species Act, Magnuson-Stevens Fishery Conservation and Management Act, Marine Mammal Protection Act, and National Historic Preservation Action) as discussed in Appendix A, *Required Environmental Permits and Consultations* of this Final EIS. Please note that not all of these mitigation measures are within BOEM's statutory and regulatory authority and some may be required by other governmental entities. Additional measures identified during development of this EIS are listed in Table G-3, and Table G-4 identifies measures that may be required by authorizations and permits issued to the lessee.

If BOEM decides to approve the COP, the Record of Decision (ROD) will state which of the mitigation and monitoring measures identified by BOEM in Table G-2 and Table G-3 have been adopted and, if not, why they were not. Where the impacts of an action alternative are determined through the inclusion of any mitigation and monitoring measures, all of those measures will be incorporated in the ROD if that alternative is selected. The ROD will describe the specific terms and conditions of these measures for which compliance is required (40 Code of Federal Regulations [CFR] 1505.3). SouthCoast Wind would be required to certify compliance with these terms and conditions under 30 CFR 285.633(a). Furthermore, pursuant to 30 CFR 585.634(b), BOEM will periodically review the activities conducted under the approved COP, with the frequency and extent of the review based on the significance of any changes in available information and on onshore or offshore conditions affecting, or affected by, the activities conducted under the COP.

Monitoring may be required to evaluate the effectiveness of mitigation measures or to identify if resources are responding as predicted to impacts from the Proposed Action. This monitoring would typically be developed in coordination among BOEM and agencies with jurisdiction over the resource to be monitored. The information generated by monitoring may be used to (1) modify how a mitigation measure identified in the COP or ROD is being implemented, (2) revise or develop new mitigation or monitoring measures for which compliance would be required under the COP in accordance with 30 CFR 285.633(a), (3) develop measures for future projects, or (4) contribute to regional efforts for better understanding of the impacts and benefits resulting from offshore wind energy projects in the Atlantic (e.g., a potential cumulative impact assessment tool). Unless specified, the proposed mitigation measures described below would not change the impact ratings on the affected resource, as described in Chapter 3 of the Final EIS, but would further reduce expected impacts or inform the development of additional mitigation measures if required.

G.1 Applicant-Proposed Measures

Table G-1 presents applicant-proposed measures as identified in SouthCoast Wind's COP (SouthCoast Wind 2024). In the last column of the table BOEM has identified the anticipated agency that would enforce each measure or whether the measure is a best practice and not an enforceable measure. Attachment G-1 contains the applicant-proposed mitigation measures proposed by SouthCoast Wind as part of its Request for Incidental Take Regulations application under the Marine Mammal Protection Act, dated September 2022 and a revised application dated March 2024. The National Marine Fisheries Service (NMFS) published a Notice of Receipt of the application in the Federal Register on October 17, 2022. These mitigation measures are subject to change pending NMFS's development of final regulations. Additional lessee authorization and permit conditions are included in Table G-4.

Table G-1. Applicant-proposed measures

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
Applicant-Proposed Measures from COP Volume 2, Table 16-1 (SouthCoast Wind 2024)				
Construction	**Seabed or Ground Disturbance** Seabed preparation, offshore component installation, and vessel anchoring/spudding	• SouthCoast Wind will use BMPs to minimize sediment mobilization during offshore component installation • SouthCoast Wind, when feasible, will use technologies that minimize sediment mobilization and seabed sediment alteration for cable burial operations • SouthCoast Wind, where practical and safe, will utilize DP vessels • SouthCoast Wind will utilize HDD for sea-to-shore transition	Site Geology	Best practice - not an enforceable measure
O&M	**Seabed or Ground Disturbance** Routine offshore operation and maintenance	• SouthCoast Wind will utilize scour protection methods to avoid developing scour holes at the base of structures • SouthCoast Wind will bury submarine cables at depths to guard against exposure from seabed mobility	Site Geology	BSEE
Decommissioning	**Seabed or Ground Disturbance** Offshore component decommissioning	• SouthCoast Wind will use BMPs to minimize sediment mobilization during decommissioning	Site Geology	Best practice - not an enforceable measure
Construction, O&M, Decommissioning	**Seabed or Ground Disturbance** Scour development	• SouthCoast Wind will utilize scour protection methods to avoid developing scour holes at the base of structures • SouthCoast Wind will bury submarine cables at depths to guard against exposure from seabed mobility	Physical Oceanography and Meteorology	BSEE
Construction, O&M	**Planned Discharges: Air Emissions** Vehicles, onshore and offshore construction	• SouthCoast Wind will ensure that vessels used for construction will use the jurisdictionally required compliant fuel, e.g., ultra-low sulfur diesel or a fuel with less emissions	Air Quality	Best practice - not an enforceable measure

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
	equipment, drones, helicopters and generators	• SouthCoast Wind will ensure fuels used for construction equipment comply with EPA or equivalent emissions standards • SouthCoast Wind will use low-NOx engines when possible • SouthCoast Wind will engage with EPA on how to satisfy Best Available Control Technology		
Construction, O&M, Decommissioning	**Seabed or Ground Disturbance** Offshore component installation, routine offshore O&M, vessel anchoring, and decommissioning	• SouthCoast Wind will select and use BMPs including the use of a SWPPP to minimize sediment mobilization during offshore construction of WTGs and OSPs, scour protection placement, and HDD operations • SouthCoast Wind, when feasible, will use technologies that minimize sediment mobilization and seabed sediment alteration for cable burial operations	Water Quality	Best practice – not an enforceable measure
Construction, O&M, Decommissioning	**Seabed or Ground Disturbance** Onshore component installation and decommissioning	• SouthCoast Wind will follow BMPs, including the use of a SWPPP, during onshore construction activities to control sedimentation and erosion	Water Quality	BSEE, USCG, USACE, EPA, MassDEP and RIDEM
Construction, O&M, Decommissioning	**Planned Discharges** Stormwater runoff, routine releases, and duct bank installation	• SouthCoast Wind will follow USCG requirements at 33 CFR Part 151 and 46 CFR Part 162 regarding bilge and ballast water • SouthCoast Wind will require all Project vessels to comply with regulatory requirements related to the prevention and control of discharges and accidental spills including EPA requirements under the EPA 2013 Vessel General Permit and state and local government requirements	Water Quality	BOEM, BSEE and USCG
Construction, O&M, Decommissioning	**Accidental Events/Natural Hazards** Unplanned releases	• SouthCoast Wind will comply with the regulatory requirements related to the prevention and control of discharges and accidental spills as documented in the proposed Project's OSRP	Water Quality	BOEM, BSEE, USACE and USCG

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• SouthCoast Wind's SWPPP will include a Project-specific SPCC plan to prevent inadvertent releases of oils and other hazardous materials to the environment to the extent practicable • SouthCoast Wind will have an HDD Contingency Plan in place to mitigate, control, and avoid unplanned discharges related to HDD activities		
Construction, O&M, Decommissioning	**Seabed or Ground Disturbance** Habitat loss/fragmentation **Introduced Sound** Avoidance/ displacement **Presence of Structures** Collision with WTGs, avoidance/displacement and barrier effects, and habitat loss/modification	• SouthCoast Wind will site the proposed Project to avoid locating Project components in or near areas of known important or high bird use (e.g., nesting, foraging and overwintering areas, migratory staging or resting areas) • SouthCoast Wind will incorporate use of HDD at landfall locations to avoid disturbance to shorelines and coastal habitats to the extent practicable • SouthCoast Wind will coordinate with MassWildlife, RIDEM, and USFWS to identify appropriate mitigation measures	Birds	BOEM, USFWS, USACE, MassDEP and RIDEM
Construction, Decommissioning	**Changes in Ambient Lighting** Displacement/attraction and collision with WTGs **Vessel Operations** Collision with vessels and avoidance/ displacement	• SouthCoast Wind will minimize lighting, to the extent practicable, to reduce potential attraction of birds to vessels during construction activities	Birds	BOEM, BSEE
Construction, O&M, Decommissioning	**Planned Discharges** Disturbance or fatality **Accidental Events** Oiling or fatality from accidental spills, and ingestion of marine debris	• SouthCoast Wind will use approved OSRP mitigation measures, as necessary, to prevent birds from going to affected areas including chumming, hazing, and relocating to unaffected areas	Birds	BOEM, BSEE, and USFWS
O&M	**Changes in Ambient Lighting** Displacement/attraction and collision with WTGs	• SouthCoast Wind will develop and implement a Post-Construction Monitoring Plan	Birds	BOEM, BSEE, and USFWS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
O&M	**Changes in Ambient Lighting** Displacement/attraction and collision with WTGs	• SouthCoast Wind will ensure that lighting on WTGs will be executed in accordance with FAA regulations • Lighting on OSPs will be minimized to that required for navigation safety to reduce potential attraction of birds to the extent practicable		BOEM, BSEE
Construction, O&M, Decommissioning	**Ground Disturbance** Habitat loss/fragmentation **Introduced Sound** Behavioral disturbance **Changes in Ambient EMF** Displacement/attract-ion	• SouthCoast Wind will site Project components to avoid locating onshore facilities or landfall sites in or near significant fish and wildlife habitats, including known hibernacula, maternal roosting colonies or other concentration areas as practicable. The proposed onshore substation site and converter stations will be constructed in primarily open, developed areas • Onshore export cables will be buried underground beneath local roadways from landfall to the onshore substation site • SouthCoast Wind will coordinate with MassWildlife, RIDEM, and USFWS to identify appropriate mitigation measures	Bats	BSEE, USFWS, MassDEP and RIDEM
Construction, O&M, Decommissioning	**Changes in Ambient Lighting** Displacement/ attraction	• SouthCoast Wind will ensure that lighting will be minimized to reduce potential attraction of bats to vessels and vehicles during construction activities within the Onshore and Offshore Project Areas to the extent practicable	Bats	Best practice – not an enforceable measure
Construction, O&M, Decommissioning	**Tree Clearing** Roost disturbance from tree trimming or removal	• SouthCoast Wind will consult with BOEM and the USFWS to discuss BMPs available to avoid and minimize potential effects from construction/decommissioning to bats	Bats	BOEM and USFWS
O&M	**Presence of Structures** Collisions with WTGs	• SouthCoast Wind will develop and implement a Post-Construction Monitoring Plan	Bats	BOEM, BSEE, USFWS, MassDEP and RIDEM

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
Construction, O&M	**Ground Disturbance** Habitat loss/fragmentation **Introduced Sound** Behavioral disturbance and displacement **Changes in EMF** Behavioral disturbance	• SouthCoast Wind will site Project components to avoid locating onshore facilities and landfall sites in or near significant fish and wildlife habitats to the greatest extent practicable. The proposed onshore substation site and the converter station site will be constructed in primarily open, developed areas. • SouthCoast Wind will train construction staff on biodiversity management and environmental compliance requirements • SouthCoast Wind will bury the onshore export cables underground beneath local roadways from landfall to the onshore substation site.	Terrestrial Vegetation and Wildlife	BOEM, USFWS, NMFS, MassDEP and RIDEM
Construction, Decommissioning	**Changes in Ambient Lighting** Displacement/attraction	• If tree clearing is required, SouthCoast Wind will conduct habitat assessments and presence/absence surveys and will coordinate with MassWildlife, RIDEM, and USFWS as appropriate • SouthCoast Wind will, to the extent practicable, conduct construction activities outside of periods when highly sensitive species are likely to be present • SouthCoast Wind will implement erosion and sediment control measures in areas adjacent to water resources, such as wetlands, ponds, and other waterbodies, or in areas with significant grades that would make them prone to erosion • SouthCoast Wind will implement a Vegetation Management Plan as approved by NHESP, RIDEM, and the Massachusetts Department of Agricultural Resources	Terrestrial Vegetation and Wildlife	USFWS, MassDEP and RIDEM
Construction	**Changes in Ambient Lighting** Displacement/attraction	• SouthCoast Wind will ensure lighting will be minimized to the extent practicable to reduce potential displacement or attraction of wildlife species to Project sites during construction activities in the Project Area	Terrestrial Vegetation and Wildlife	Best practice – not an enforceable measure

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
Construction, O&M, Decommissioning	**Operation of Equipment and Heavy Machinery** Collision with equipment and heavy machinery Collision with utility lines or electrocution	• Vehicle speed limits will be enforced at all Project sites to minimize potential for vehicle collisions with wildlife • SouthCoast Wind will conduct presence/absence surveys; surveys for protected plant and wildlife species will be completed as needed to inform the detailed engineering and design of the Project facilities	Terrestrial Vegetation and Wildlife	Best practice – not an enforceable measure
Construction, Decommissioning	**Planned Discharges** Disruption of water flow or alteration of turbidity	• SouthCoast Wind will ensure that standard construction BMPs (including erosion and sediment control measures) will be implemented to avoid dewatering discharge scour and siltation to nearby receiving waters, including wetlands	Terrestrial Vegetation and Wildlife	Best practice – not an enforceable measure
Construction, Decommissioning	**Accidental Events** Release of hazardous materials into environment	• SouthCoast Wind will implement a construction-phase OSRP to provide procedures for containing, cleaning, and reporting any accidental spills of oil fuel, or other hazardous materials	Terrestrial Vegetation and Wildlife	BOEM, BSEE and USCG
O&M	**Ground Disturbance** Habitat loss/fragmentation **Introduced Sound** Behavioral disturbance and displacement **Changes in Ambient Lighting** Displacement/attract-ion	• SouthCoast Wind will implement a Vegetation Management Plan as approved by NHESP, RIDEM, and the Massachusetts Department of Agricultural Resources	Terrestrial Vegetation and Wildlife	Best practice - not an enforceable measure
O&M	**Accidental Events** Release of hazardous materials into environment	• SouthCoast Wind will implement an operations-phase OSRP to provide procedures for containing, cleaning, and reporting any accidental spills of oil fuel, or other hazardous materials	Terrestrial Vegetation and Wildlife	BOEM,BSEE and USCG
Decommissioning	**Ground Disturbance** Habitat loss/fragmentation **Introduced Sound**	• SouthCoast Wind will implement a Vegetation Management Plan approved by NHESP, RIDEM, and the Massachusetts Department of Agricultural Resources	Terrestrial Vegetation and Wildlife	Best practice - not an enforceable measure

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
	Behavioral disturbance and displacement **Changes in Ambient Lighting** Displacement/attract-ion	• SouthCoast Wind will implement erosion and sediment control measures in accordance with applicable regulations		
Construction, Decommissioning	**Ground Disturbance** Temporary habitat disturbance	• SouthCoast Wind will implement erosion and sediment control measures in accordance with Massachusetts and Rhode Island regulations and industry BMPs throughout the Onshore Project Area to abate technical and biological erosion	Wetlands and Waterbodies	Best practice - not an enforceable measure
Construction, Decommissioning	**Planned Discharges** Dewatering and stormwater runoff	• If groundwater is encountered, SouthCoast Wind will perform dewatering measures using standard construction BMPs for dewatering, including, but not limited to, use of temporary settling basins, dewatering filter bags, or temporary holding or frac tanks • SouthCoast Wind will direct dewatering wastewaters to well-vegetated uplands away from wetlands or other water resources to allow for infiltration to the soil of the discharged water • SouthCoast Wind will place construction mats to minimize soil disturbance in any wetland areas that cannot be avoided or are required to be temporarily crossed	Wetlands and Waterbodies	Best practice - not an enforceable measure
Construction	**Accidental Events** Release of hazardous materials into environment	• SouthCoast Wind will always require the construction contractor to have spill control and containment kits on site to allow for immediate response and cleanup in the event of an accidental release of fuel, oils, or other hazardous materials • Implementation of BMPs, the SMS, and a SWPPP for construction as well as an emergency response procedure to avoid, control, and address any accidental releases during construction activities	Wetlands and Waterbodies	BOEM, BSEE, USACE and USCG

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• SouthCoast Wind and their construction contractor will store petroleum products in upland areas more than 100 feet (30.5 meters) from wetlands and waterbodies • Equipment will not be parked overnight within 100 feet (30.5 meters) of a wetland or waterbody, with an exception being for equipment that cannot be practically moved. Temporary containment will be required for equipment that cannot be practically moved and must be parked overnight within 100 feet (30.5 meters) of a wetland or other water resources • SouthCoast Wind will use a secondary containment system for refueling that needs to occur within 100 feet (30.5 meters) of wetlands to contain any minor amounts of fuel inadvertently dripped or released during refueling • SouthCoast Wind will set up cement cleanout tubs in areas at least 100 feet (30.5 meters) from wetlands or other water resources to contain and hold any residual cement and washout from cement trucks prior to their departure from the site		
O&M	**Planned Discharges** Dewatering and stormwater runoff	• Discharges as a result of dewatering will be managed in accordance with the requirements for applicable EPA, MassDEP, RIDEM, and/or local regulations pertaining to dewatering	Wetlands and Waterbodies	BOEM, EPA, MassDEP AND RIDEM
O&M	**Accidental Events** Release of hazardous materials into environment	• SouthCoast Wind and their construction contractor will store petroleum products in upland areas more than 100 feet (30.5 meters) from wetlands and waterbodies	Wetlands and Waterbodies	BOEM, BSEE and USCG
Decommissioning	**Accidental Events** Release of hazardous materials into environment	• SouthCoast Wind will always require the decommissioning contractor to have spill control and containment kits on site to allow for immediate response and cleanup in the event of an accidental release of fuel, oils, or other hazardous materials	Wetlands and Waterbodies	BOEM, BSEE and USCG

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• SouthCoast Wind will implement BMPs, an SMS, and an SWPPP as well as an emergency response procedure to avoid, control and address any accidental releases during decommissioning activities as applicable • Equipment will not be parked overnight within 100 feet (30.5 meters) of a wetland or waterbody, with an exception being for equipment that cannot be practically moved • Temporary containment will be required for equipment that cannot be practically moved and must be parked overnight within 100 feet (30.5 meters) of a wetland or other water resources • The use of a secondary containment system for refueling that needs to occur within 100 feet (30.5 meters) of wetlands to contain any minor amounts of fuel inadvertently dripped or released during refueling		
Construction, O&M	**Seabed or Ground Disturbance** **Planned Discharges/ Accidental Events** Project installation and vessel O&M	• SouthCoast Wind will select sites for construction that avoid areas of sensitive seafloor and benthic habitat to the extent practicable • SouthCoast Wind will utilize HDD for nearshore export cable installation • SouthCoast Wind will minimize trench and sidecasting widths for export cable installation and anchor outside of eelgrass beds where possible • To the extent possible, SouthCoast Wind will avoid use of anchored vessels near known eelgrass beds	Coastal Habitats	BOEM, USACE and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
Construction	**Change in Ambient Lighting**	• Any effects of changes to ambient lighting will be limited to proposed landfall locations where eelgrass beds or clusters of macroalgae were identified along the northern portions of the proposed export cable corridors	Coastal Habitats	BOEM and NMFS
Construction	**Actions that May Displace Biological Resources (Eelgrass and Macroalgae)** **Actions that May Cause Direct Injury or Death**	• Offshore export cable installation and the location of the HDD exit pit are planned for outside the mapped eelgrass extents at the cable landing locations	Coastal Habitats	BOEM, USACE, and NMFS
O&M	**Change in Ambient EMF**	• EMF modeling conducted for the proposed Project indicates that HDD installation in nearshore areas will reduce, but not entirely eliminate magnetic fields in the area where eelgrass beds or clusters of macroalgae were identified.	Coastal Habitats	Best practice - not an enforceable measure
Decommissioning	**Seabed or Ground Disturbance**	• The proposed Project's offshore export cables may be left in place to minimize environmental effects, thus resulting in minimal or no sea bottom disturbance	Coastal Habitats	Best practice - not an enforceable measure
Decommissioning	**Change in Ambient Lighting**	• The proposed Project's offshore export cables may be left in place to minimize environmental effects, thus resulting in no change to ambient lighting	Coastal Habitats	Best practice - not an enforceable measure
Decommissioning	**Displacement of Eelgrass and Macroalgae** **Actions that May Cause Direct Injury or Death of Biological Resources**	• The offshore export cables may be left in place to minimize environmental effects, thus resulting in no displacement	Coastal Habitats	Best practice - not an enforceable measure
Construction, Decommissioning	**Introduced Sound into the Environment (In-air or Underwater)** Behavioral disturbance	• SouthCoast Wind will incorporate lower-impact construction methods, where possible	Benthic and Shellfish Resources	Best practice - not an enforceable measure

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
Construction, O&M, Decommissioning	**Seabed or Ground Disturbance/ Planned Discharges/ Accidental Events** Harassment/mortality	• SouthCoast Wind will design the scour protection system to reduce and minimize scour and sedimentation to the extent practicable	Benthic and Shellfish Resources	Best practice - not an enforceable measure
Construction, Decommissioning	**Actions that May Displace Biological or Cultural Resources, or Human Uses** Habitat Loss	• SouthCoast Wind will use HDD at landings to avoid disturbance to nearshore productive shellfish beds to the extent practicable • SouthCoast Wind will select lower-impact construction methods, where possible • SouthCoast Wind will select corridor and micro-route cables within selected corridor to avoid complex habitats, where possible • SouthCoast Wind's Project cable burial layout was designed to minimize length of cable needed • SouthCoast Wind will bury cables, where possible, to allow for benthic recolonization after construction is complete	Benthic and Shellfish Resources	BOEM and NMFS
O&M	**Actions that May Displace Biological or Cultural Resources, or Human Uses** Habitat Loss	• Presence of Project foundation areas, scour protection, and cable burial would allow for benthic recolonization	Benthic and Shellfish Resources	Best practice – not an enforceable measure
O&M	**Change in Ambient EMF** Displacement/harassment	• SouthCoast Wind will employ industry standard cable burial and cable shielding methods to reduce potential effects • SouthCoast Wind's Project cable burial layout was designed to minimize length of cable needed to reduce potential effects	Benthic and Shellfish Resources	BSEE
Construction, Decommissioning	**Introduced Sound into the Environment (in-air or underwater)** Behavioral disturbance	• SouthCoast Wind will incorporate soft start methods, to the extent practicable, during initial pile driving activities to allow mobile finfish and invertebrates to migrate away from the area	Finfish and Invertebrates	BOEM, BSEE, USACE, and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• SouthCoast Wind will employ sound-attenuation measures (e.g., bubble curtains, insulated piles) • SouthCoast Wind will limit duration of pile driving activities to reduce sound propagation/sound exposure		
Construction, O&M, Decommissioning	**Seabed or Ground Disturbance** Harassment/ mortality	• SouthCoast Wind will design the scour protection system to reduce and minimize scour and sedimentation	Finfish and Invertebrates	Best practice – not an enforceable measure
Construction, O&M, Decommissioning	**Habitat Disturbance and Modification** Habitat Loss and artificial reef effect from	• SouthCoast Wind will design the sea-to-shore transition to reduce the dredging footprint and effects on benthic organisms (e.g., cofferdam and/or gravity cell) • SouthCoast Wind will incorporate use of HDD at landing(s) and avoid disturbance to finfish and invertebrate EFH to the extent practicable • SouthCoast Wind will incorporate use of HDD of subsea cables, as appropriate, to minimize spatial and temporal effects on benthic organisms	Finfish and Invertebrates	Best practice - not an enforceable measure
Construction, Decommissioning	**Change in Ambient Lighting/ Planned Discharges/ Accidental Events** Displacement, harassment, and mortality	• SouthCoast Wind will incorporate use of HDD at landings and avoid disturbance to finfish and invertebrate EFH to the extent practicable	Finfish and Invertebrates	Best practice - not an enforceable measure
Construction	**Change in Ambient Lighting/ Planned Discharges/ Accidental Events** Displacement, harassment and mortality	• SouthCoast Wind will install offshore export cables and inter-array cables to target burial depths and use cable shielding materials to minimize effects of EMFs	Finfish and Invertebrates	BSEE
Construction, O&M, Decommissioning	**Introduced Sound into the Environment (in-air or underwater)**	• When technically feasible, SouthCoast Wind will employ a “ramp-up” of the HRG survey equipment at	Marine Mammals	BOEM, BSEE, USACE, and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
	Behavioral disturbance	the start or re-start of HRG survey activities to minimize sound source effects. • SouthCoast Wind will ensure that active acoustic sound sources will not be activated until the PSO has reported the clearance zone clear of all marine mammals after the appropriate amount of pre-clearance watch time has passed based on the proposed Project's Incidental Take Authorization • SouthCoast Wind will employ sound-attenuation measures (e.g., bubble curtains, insulated piles, etc.) • SouthCoast Wind will limit duration of pile driving activities to reduce sound propagation/sound exposure • SouthCoast Wind will incorporate soft start methods during initial pile driving activities to allow marine mammals to migrate away from the area of effect • SouthCoast Wind will employ shut-down procedure when protected species are detected in their respective shutdown zones in the Project Area • SouthCoast Wind will ensure that Project activities adhere to NMFS-authorized Incidental Take Authorization for the proposed Project • SouthCoast will implement measures as identified in Appendix O, Marine Mammal and Sea Turtle Monitoring and Mitigation Plan • To reduce impacts on NARW and other marine mammals, SouthCoast Wind does not intend to conduct pile-driving activities from January 1 through April 30 • SouthCoast Wind will not conduct pile driving activities within the Enhanced Mitigation Area from June 1 through October 31		
Construction, O&M, Decommissioning	**Vessel Operations** Serious injury or mortality	• SouthCoast Wind will ensure all vessels maintain a separation distance of 328 feet (100 meters) or greater from any sighted ESA-listed whales or humpback whales (except NARW). Ensure that the following	Marine Mammals	BOEM, BSEE, and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		avoidance measures are taken if a vessel comes within 328 feet (100 meters) of whale: • If underway, the vessel must reduce speed and shift the engine to neutral and must not engage the engines until the whale has moved beyond 328 feet (100 meters). • If stationary, the vessel must not engage engines until the whale has moved beyond 328 feet (100 meters). • SouthCoast Wind will ensure all vessels maintain a separation distance of 1,640 feet (500 meters) or greater from any sighted NARW or unidentified large marine mammal • If a vessel is stationary, the vessel must not engage engines until the NARW has moved beyond 328 feet (100 meters) • SouthCoast Wind will ensure that all vessels underway do not divert to approach any marine mammals • SouthCoast Wind will ensure that all vessels maintain a separation distance of 164 feet (50 meters) or greater from any sighted small cetacean or seal, except when a small cetacean or seal approaches the vessel • If a small cetacean or seal approaches any vessel underway, the Project vessel underway must avoid excessive speed or abrupt changes in direction to avoid injury to the animal • SouthCoast Wind will require all vessels operating within and transiting to/from the Project Area comply with the vessel strike avoidance measures specified in lease stipulations, including: • Ensure that vessel operators and crews maintain a vigilant watch for marine mammals and slow down or stop their vessel to avoid striking these protected species		

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• Ensure that vessels 65 feet (19.8 meters) in length or greater that operate between November 1 through July 31, operate at speeds of 10 knots (11.5 mph) or less • Vessel operators should monitor NMFS NARW reporting systems all year and whenever a Dynamic Management Area is established within any area vessels operate • Ensure that all vessel operators comply with 10-knot (18.5 kilometers per hour [km/hr]) speed restrictions in any Dynamic Management Area • SouthCoast Wind will ensure that all vessel operators reduce vessel speed to 10 knots or less when mother/calf pairs, pods, or large assemblages of marine mammals are observed near an underway vessel • SouthCoast Wind will implement measures as identified in Appendix O, Marine Mammal and Sea Turtle Monitoring and Mitigation Plan		
Construction, O&M, Decommissioning	**Seabed or Ground Disturbance** Displacement/harassment **Habitat Disturbance and Modification** Habitat loss and artificial reef effect	• SouthCoast Wind will implement measures as identified in Appendix O, Marine Mammal and Sea Turtle Monitoring and Mitigation Plan	Marine Mammals	BOEM, BSEE, and NMFS
Construction, O&M, Decommissioning	**Entanglement** Harassment/mortality **Accidental Events** Ingestion/entanglement	• SouthCoast Wind will adhere to all regulations under the EPA Clean Water Act • SouthCoast Wind will ensure that any structures or devices attached to the seafloor for continuous periods greater than 24 hours use the best available mooring systems (vertical and float lines, swivels, shackles, and anchor designs) for minimizing the risk of entanglement or entrainment of marine mammals while still ensuring the safety and integrity of the structure or device	Marine Mammals	BOEM, BSEE, EPA and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• SouthCoast Wind will ensure that all mooring lines and ancillary attachment lines use one or more of the following measures to reduce entanglement risk: shortest practicable line length, rubber sleeves, weak-links chains, cables, or similar equipment types that prevent lines from looping or wrapping around animals, or entrapping protected species • If an entangled live or dead marine protected species is reported, SouthCoast Wind personnel must provide any assistance to authorized stranding response personnel as requested by BOEM or NMFS • SouthCoast Wind will implement measures as identified in Appendix O, Marine Mammal and Sea Turtle Monitoring and Mitigation Plan		
Construction, O&M, Decommissioning	**Planned Discharges/ Accidental Events** Harassment/mortality	• SouthCoast Wind will use approved OSRP mitigation measures to prevent animals from going to affected area including translocation to unaffected areas as necessary • SouthCoast Wind will implement measures as identified in Appendix O, Marine Mammal and Sea Turtle Monitoring and Mitigation Plan • To minimize potential impacts on zooplankton from impingement and entrainment, the northernmost HVDC converter OSP will be located outside of a 10kilometer buffer of the 30-meter isobath from Nantucket Shoals.	Marine Mammals	BOEM, BSEE, and NMFS
Construction, O&M, Decommissioning	**Introduced Sound into the Environment (in-air or underwater)** Behavioral disturbance	• SouthCoast Wind will incorporate soft start methods during initial pile driving activities to allow sea turtles to migrate away from the area of effect • SouthCoast Wind will ensure that active acoustic sound sources will not be activated until the PSO has reported the clearance zone clear of all sea turtles after the appropriate amount of pre-clearance watch time has	Sea Turtles	BOEM, BSEE, USACE, and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		passed based on the proposed Project's Incidental Take Authorization • SouthCoast Wind will employ sound-attenuation measures (e.g., bubble curtains, insulated piles, etc.) • SouthCoast Wind will limit duration of pile driving activities to reduce sound propagation/sound exposure • SouthCoast Wind will employ shut-down procedure when protected species are detected in their respective shutdown zones in the Project Area • SouthCoast Wind will ensure that Project activities adhere to NMFS-authorized Incidental Take Authorization for the proposed Project • SouthCoast Wind will implement measures as identified in Appendix O, Marine Mammal and Sea Turtle Monitoring and Mitigation Plan		
Construction, O&M, Decommissioning	**Vessel Operations** Serious injury or mortality	• SouthCoast Wind will ensure that all vessels underway do not intentionally approach any sighted sea turtle • SouthCoast Wind will ensure that all vessels maintain a separation distance of 164 feet (50 meters) or greater from any sighted sea turtles • SouthCoast Wind will require all vessels operating within and transiting to/from the Lease Area comply with the vessel strike avoidance measures specified in lease stipulations or NMFS authorization, including: • Ensure that vessel operators and crews maintain a vigilant watch for sea turtles and slow down or stop their vessel to avoid striking these protected species • Employ reporting system to NMFS in the event of a vessel strike • SouthCoast Wind will implement measures as identified in Appendix O, Marine Mammal and Sea Turtle Monitoring and Mitigation Plan	Sea Turtles	BOEM, BSEE, and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
Construction, O&M, Decommissioning	**Habitat Disturbance and Modification** Reduced prey availability/ habitat loss	• SouthCoast Wind will design scour protection system to reduce and minimize scour and sedimentation • SouthCoast Wind will implement measures as identified in Appendix O, Marine Mammal and Sea Turtle Monitoring and Mitigation Plan	Sea Turtles	BOEM, BSEE, and NMFS
Construction, O&M, Decommissioning	**Entanglement** Harassment/mortality or ingestion/entanglement from marine debris	• SouthCoast Wind will adhere to all regulations under the EPA Clean Water Act. SouthCoast Wind will ensure that any structures or devices attached to the seafloor for continuous periods greater than 24 hours use the best available mooring systems (vertical and float lines, swivels, shackles, and anchor designs) for minimizing the risk of entanglement or entrainment of sea turtles, while still ensuring the safety and integrity of the structure or device • SouthCoast Wind will ensure that all mooring lines and ancillary attachment lines will use one or more of the following measures to reduce entanglement risk: shortest practicable line length, rubber sleeves, weak-links chains, cables or similar equipment types that prevent lines from looping or wrapping around animals or entrapping protected species • If an entangled live or dead marine protected species is reported, SouthCoast Wind personnel must provide any assistance to authorized stranding response personnel as requested by BOEM or NMFS • SouthCoast Wind will implement measures as identified in Appendix O, Marine Mammal and Sea Turtle Monitoring and Mitigation Plan	Sea Turtles	BOEM, BSEE, EPA and NMFS
Construction, O&M, Decommissioning	**Planned Discharges/ Accidental Events** Harassment/mortality	• SouthCoast Wind will use approved OSRP mitigation measures to prevent animals from going to affected area including translocation to unaffected areas	Sea Turtles	BOEM, BSEE, and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• SouthCoast will implement measures as identified in Appendix O, Marine Mammal and Sea Turtle Monitoring and Mitigation Plan		
O&M	**Changes in Ambient EMF** Displacement/harassment	• Employ industry standard cable burial and cable shielding methods to reduce potential effects	Sea Turtles	Best practice - not an enforceable measure
Construction, O&M, Decommissioning	**Seabed or Ground Disturbance/Sediment Suspension and Deposition** Unanticipated discovery of underwater cultural heritage	• SouthCoast Wind will maintain avoidance buffers around identified [marine archaeological resources], as appropriate • SouthCoast Wind will mark identified [ASLFs] for avoidance, as appropriate • SouthCoast Wind will continue to develop, in consultation with the [tribal nations] and applicable federal and state agencies, an Unanticipated Discovery Plan in the unlikely event unidentified and an unanticipated underwater cultural heritage [marine cultural resources and human remains] is encountered • Under the [UDP] (COP Volume II, Appendix Q.1; SouthCoast Wind 2024), in the event that a potential cultural resource is discovered during construction activities, all bottom-disturbing activities in the area of discovery will cease and every effort will be made to avoid or minimize damage to the potential [marine] cultural resource(s) • Training to identify archaeological resources will be provided by the QMA for resident engineers and contractor field supervisors prior to the implementation of Project and contractor personnel	Cultural – Marine Archaeological Resources	BOEM, BSEE, and USACE
Construction	**Ground Disturbance** Unanticipated discovery of terrestrial archaeological resources from ground disturbance	• SouthCoast Wind will site the onshore Project components in locations that minimize impacts on, or avoid, potential terrestrial archaeological resources, to the extent practicable	Cultural – Terrestrial Archaeological Resources	BOEM, BSEE, and USACE

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• SouthCoast Wind will monitor archaeological subsurface testing during construction in areas determined to have a moderate to high potential for undiscovered archaeological resources • SouthCoast Wind will implement an Unanticipated Discovery Plan that will include stop-work and notification procedures to be followed if a cultural resource is encountered during installation • SouthCoast Wind will conduct additional site-specific site evaluation and site mitigation if determined to be warranted due to the identification of archaeological resources that exhibit a potential for listing in the NRHP • SouthCoast Wind will perform fieldwork in accordance with current standards and consultation with the MHC and RIHPHC • SouthCoast Wind will work with a cultural resource consultant (CRC) to determine the need for a site visit by the CRC within 24 hours upon discovery of a potential cultural resource • SouthCoast Wind will conduct necessary archaeological investigations under archaeological permits issued by the MHC and/or RIHPHC • SouthCoast Wind will handle any discoveries of human remains in accordance with the appropriate state requirements and if they appear to be Native American will be guided by the policy statement adopted by the ACHP		
Construction, O&M, Decommissioning	**Accidental Events** Damage to unanticipated archaeological resources from accidental events	• SouthCoast Wind will implement BMPs throughout the proposed Project phases to minimize potential effects, including accidental releases • SouthCoast Wind will develop and implement a SMS and OSRP to avoid, control and address any accidental releases during all proposed Project activities	Cultural – Terrestrial Archaeological Resources	BOEM, BSEE, and USACE

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• A SPCC plan will be developed for the Project, as appropriate		
Construction, O&M, Decommissioning	**Altered Visual Conditions/ Changes to Ambient Lighting** Change in resource setting	• SouthCoast Wind proposes to design the onshore substation to mitigate visual effects to the extent feasible, improving site aesthetics by adhering to landscape codes and edge treatments, and improving substation building architecture to fit local context • SouthCoast Wind will work with the Towns of Falmouth, if Falmouth is the selected POI for Project 2, with Somerset, and with Portsmouth to ensure the lighting scheme complies with Town requirements • SouthCoast Wind will ensure the design of outdoor light fixtures at the onshore substation complies with night sky lighting standards to the extent practicable • SouthCoast Wind will keep lighting at the onshore substation to a minimum; only a few lights will be illuminated for security reasons on dusk-to-dawn sensors and other lights will utilize motion-sensing switches. The majority of lights will be switched on for emergency situations only • SouthCoast Wind will implement ADLS to reduce nighttime visual impacts • SouthCoast Wind will continue to develop Historic Property Treatment Plans to resolve any adverse visual effects on historic properties • SouthCoast Wind will develop and implement a landscape vegetation and screening plan as part of the Historic Property Treatment Plan for the Oak Grove Cemetery in Falmouth, Massachusetts, if Falmouth is the selected POI for Project 2	Cultural – Visual Effects to Historic Properties	BOEM, BSEE, USACE, MassDEP and RIDEM
Construction, O&M, Decommissioning	**Altered Visual Conditions/ Changes to Ambient Lighting**	• SouthCoast Wind proposes to design the substation and converter stations to mitigate visual effects to the extent feasible, including height, location, and color	Visual Resources	BOEM and BSEE

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
	Change in seascape/ landscape	• SouthCoast Wind proposes to design the onshore substation and converter stations to mitigate visual effects to the extent feasible, including improving site aesthetics by adhering to landscape codes and edge treatments, and improving building architecture to fit local context. • SouthCoast Wind will work with the Towns of Falmouth, if Falmouth is the selected POI for Project 2, with Somerset, and with Portsmouth to ensure the lighting scheme complies with town requirements • SouthCoast Wind will design outdoor light fixtures at the onshore substation and converter stations to comply with night sky lighting standards, to the extent practicable • SouthCoast Wind will ensure lighting at the onshore substation and converter stations will be keep to a minimum. Only a few lights will be illuminated for security reasons on dusk-to-dawn sensors and other lights will utilize motion-sensing switches. The majority of lights will be switched on for emergency situations only • SouthCoast Wind will implement an ADLS		
Construction	**Activities that Introduce Sound into the Environment: In-Air Noise** HDD activities; Presence of onshore substation and converter stations	• SouthCoast Wind will minimize the amount of work conducted outside of typical construction hours • SouthCoast Wind will maintain construction equipment and use newer models to the extent practicable to provide the quietest performance • SouthCoast Wind will, when possible, use enclosures on continuously operating equipment such as compressors and generators • SouthCoast Wind will turn off construction equipment when not in use and minimize idling times; and	In-Air Acoustics	Best practice - not an enforceable measure

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• SouthCoast Wind will mitigate the impact of noisy equipment on sensitive locations by using temporary barriers or buffering distances as practicable • SouthCoast Wind will install a temporary noise barrier, if necessary, at edges of the site, where practicable and safe • SouthCoast Wind will use equipment silencers, where required, for drilling rig exhaust, mud cleaner generator exhaust, and mud pump exhaust		
O&M	**Activities that Introduce Sound into the Environment: In-Air Noise** Onshore substation and converter stations	• SouthCoast Wind will install noise barriers at edges of the site, where necessary, to meet regulatory requirements	In-Air Acoustics	Best practice - not an enforceable measure
Construction, Decommissioning	**Introduced Sound into the Environment** Displacement; Harassment; Potential injury; Avoidance	• SouthCoast Wind will utilize noise abatement systems to decrease the sound levels produced by Project activities in the water • SouthCoast Wind will employ soft-start measures allowing for a gradual increase in sound levels before the full pile driving hammer energy is reached	Underwater Acoustics	Best practice - not an enforceable measure
Construction, O&M, Decommissioning	**Workforce Hiring/ Procurement of Materials, Equipment and Services Including Port Use and Vessel Charters/Presence of Infrastructure/Influx of Non-Local Employees that Could Affect Housing** Increase in employment and economic opportunities	• SouthCoast Wind will maintain a stakeholder engagement plan with outreach and communications mechanisms to share information and gather input from external stakeholders, including potential supply chain partners, educational institutions, and workforce training providers • SouthCoast Wind will execute financial commitments pursuant to the Project's Section 83C proposal, in collaboration with the Massachusetts Clean Energy Center, including: $35 million ports and infrastructure, $10 million local innovation and entrepreneurship, $5 million applied research, $5 million workforce development, $10 million marine science, $7.5 million	Demographics and Employment, and Economics	Best practice - not an enforceable measure

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		operations and maintenance port upgrades, and $5 million low income strategic electrification • SouthCoast Wind will encourage the hiring of skilled and unskilled labor from the Project region		
Construction, Decommissioning	**Workforce Hiring/ Procurement of Materials, Equipment and Services Including Port Use and Vessel Charters/Presence of Infrastructure/ Influx of Non-Local Employees that Could Affect Housing/Vehicle Traffic/Planned Discharges: Air Emissions** Increase in employment opportunities; Contribution to the economy	• SouthCoast Wind will maintain a stakeholder engagement plan with outreach and communications mechanisms to share information and gather input from external stakeholders, including EJ communities • SouthCoast Wind will execute financial commitments pursuant to the Project's Section 83C proposal, under the terms of an agreement with Massachusetts Clean Energy Center, for initiatives that benefit EJ communities, including: $5 million workforce development; and $5 million low income strategic electrification • SouthCoast Wind will encourage the hiring of the skilled and unskilled labor from the Project region	Environmental Justice Minority and Lower Income Groups and Subsistence Resources	Best practice - not an enforceable measure
Construction, Decommissioning	**Presence of Infrastructure/ Influx of Non-Local Employees that Could Affect Housing/Vehicle Traffic/ Planned Discharges: Air Emissions** Installation, construction, and decommissioning activities	• SouthCoast Wind will develop and implement a Traffic Management Plan to minimize disruptions to the community in the vicinity of construction and installation activities, especially along the underground transmission route. The Traffic Management Plan will be developed in consultation with the municipalities and will be submitted for review and approval by municipal authorities • SouthCoast Wind will develop and implement an onshore construction schedule to minimize effects on recreational uses and tourism-related activities to the extent practicable • SouthCoast Wind will mandate one or more independent construction and environmental monitors to ensure compliance with the Traffic Management Plan and other environmental plans. SouthCoast Wind	Environmental Justice Minority and Lower Income Groups and Subsistence Resources	BOEM, USACE, MassDEP and RIDEM

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		will coordinate with the municipalities to determine the need for such monitoring		
O&M	**Workforce Hiring/ Procurement of Materials, Equipment and Services Including Port Use and Vessel Charters** Increase in employment opportunities	• SouthCoast Wind will execute commitment to make at least 75 percent of O&M local	Environmental Justice Minority and Lower Income Groups and Subsistence Resources	Best practice - not an enforceable measure
Construction, O&M, Decommissioning	**Construction Areas and Traffic/Saturation of Tourism-related Services/ Influx of Non-Local Employees that Could Affect Housing/Vehicle Traffic/ Planned Discharges: Air Emissions** Accessibility disruption and reduced enjoyment of land-based resources due to vehicle traffic	• SouthCoast Wind will develop and implement a Traffic Management Plan to minimize disruptions to residences and commercial establishments in the vicinity of onshore construction activities; pedestrian and bicycle safety and movement would also be addressed to minimize effects of construction • SouthCoast Wind will develop an onshore construction schedule to minimize effects on recreational uses and tourism related activities to the extent feasible, such as scheduling nearshore construction activities to avoid the height of the summer tourist season and coordinating with stakeholders/visitors' bureaus to schedule outside of major events taking place onshore	Recreation and Tourism	Best practice - not an enforceable measure
Construction, O&M, Decommissioning	Accessibility disruption due to saturation of tourism-related services	• SouthCoast Wind will provide a 1 nm (1.9 km) space between offshore structures (WTGs and OSPs) providing room for anticipated vessels to transit through and safely maneuver within the proposed Offshore Project Area • SouthCoast Wind will implement a comprehensive communication plan and a Fisheries Communication Plan to keep relevant marine stakeholders informed of the Project activities especially during the construction and decommissioning phases. This will include the distribution of notices to inform mariners of Project-	Recreation and Tourism	BOEM, BSEE

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		related activities within the offshore export cable corridors and Lease Area • SouthCoast Wind will utilize PATONs in accordance with IALA Guidance for the marking of man-made offshore structures (IALA, 2013), and USCG approval		
Construction, O&M, Decommissioning	Reduced enjoyment of land-based resources due to noise and air emissions	• SouthCoast Wind will implement BMPs throughout the Project phases to minimize potential effects • SouthCoast Wind will develop an onshore construction schedule to minimize effects on recreational uses and tourism-related activities to the extent feasible	Recreation and Tourism	Best practice - not an enforceable measure
Construction, Decommissioning	**Vessel Activity/Presence of Infrastructure** Vessel traffic and construction	• SouthCoast Wind will adhere to a 1 nm x 1 nm (1.9 km x 1.9 km) grid layout agreed upon with USCG will be the mitigation measure regarding this impact • SouthCoast Wind will direct communications of vessel schedules and locations during construction activities to Fisheries Liaison Officer, Fisheries Representative, local ports, and other networks • SouthCoast Wind will continue to participate in the MA/RI WEA joint developer Marine Affairs Working Group • SouthCoast Wind will implement construction safety zones in consultation with USCG and communicate to local mariners regarding upcoming and ongoing construction activities • SouthCoast Wind will work with fishermen to determine appropriate courses of action for areas that will be temporarily closed during specific construction activities • Where possible, the SouthCoast Wind will avoid sensitive areas and common fishing grounds nearshore and offshore • SouthCoast Wind will work with Port Agencies and Port agents to schedule and communicate activities to	Commercial and Recreational Fishing	BOEM, BSEE, and USCG

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		minimize impacts on fishing vessels coming in to not delay their ability to port and deliver their haul		
Construction, Decommissioning	**Actions that May Displace Biological Resources** Vessel activity and presence of infrastructure	• SouthCoast Wind will avoid locating onshore facilities or landfall sites in or near important fish habitats to the extent practicable • SouthCoast Wind will apply construction methods for cable laying activities that align with regulatory guidance • To mitigate impacts of vibration from pile-driving activities, SouthCoast Wind will utilize noise abatement systems around relevant construction activities • Certain construction activities have time-of-year restrictions to avoid, minimize, and mitigate impacts on marine organisms, such as sturgeon and winter flounder, which will also be protective of other demersal groundfish species • SouthCoast Wind will work with municipal shellfish constables to coordinate shellfish seeding with planned activities prior to construction activities • SouthCoast Wind's Boulder Relocation Plan will include a plan to document and communicate the locations of moved or newly uncovered boulders to vessels that fish in the area	Commercial and Recreational Fishing	BOEM, BSEE and NMFS
Construction, Decommissioning	**Gear Interactions** interactions	• SouthCoast Wind is currently working with commercial and recreational fishermen as well as FRs to determine construction timing and locations with fishing vessels to anticipate and avoid/minimize/mitigate gear interactions that may occur during construction • Temporary safety zone restrictions associated with construction activities will limit direct access to areas with construction activity for the safety of mariners and Project employees, but these areas will be limited spatially and temporally	Commercial and Recreational Fishing	BOEM, NMFS, and USCG

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• SouthCoast Wind will implement construction safety zones around active construction areas in consultation with USCG • SouthCoast Wind will notify mariners via LNMs of the presence and location of partially installed structures • The SouthCoast Wind FLO proactively contacts fishermen if their gear is entangled by geophysical and geotechnical survey operations and will continue to do so in later phases of the proposed Project, including during construction • SouthCoast Wind will consider the use of fixed mooring buoys at various strategic locations in the Project Area to avoid the need for anchoring		
O&M	**Vessel Activity/Presence of Infrastructure**	• SouthCoast Wind will continue to ensure that all Project-related vessels follow appropriate navigational routes and other USCG requirements, communicate via USCG LNMs, issue regular mariner updates and/or direct offshore radio communications to help mitigate risks to the commercial and recreational fishing industries, as well as other mariners • SouthCoast Wind will implement the 1 nm x 1 nm (1.9 km x 1.9 km) grid layout agreed upon with USCG and the MA/RI WEA developers • SouthCoast Wind will work with Port Agencies and Port agents to schedule and communicate activities to minimize impacts on fishing vessels • SouthCoast Wind will adopt best practice of an east-west orientation in the Lease Area with 1 nm (1.9 km) spacing between WTG/OSP rows. Layout orientation aligns with neighboring lease holders to provide fishermen consistent navigable routes to fishing grounds • SouthCoast Wind, the SouthCoast Wind FLO, and SouthCoast Wind FRs have been in close	Commercial and Recreational Fishing	BOEM, BSEE and USCG

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		communication with industry stakeholders to share information, and to avoid sensitive areas and common fishing grounds inshore and offshore to the extent practicable		
O&M	**Actions that May Displace Biological Resources** Vessel activity and presence of infrastructure	• SouthCoast Wind will install subsea cables to target burial depth and consider use cable shielding materials to minimize potential but unlikely effects of EMF • Cable routing has been designed to minimize cable crossings, cable length, and overlap with known fishing areas, while also maximizing the portion of the cable that can be buried and maintained at target burial depth, in order to mitigate potential impacts on fishing activity	Commercial and Recreational Fishing	BSEE
O&M	**Gear Interactions** Entanglement and snags	• The target cable burial depths that have been established will mitigate the risk of potential impact for anticipated gear types, regardless of penetration depth • Safety zones surrounding each foundation will partially include the scour protection on the seabed within that zone, and it is unlikely that fixed or mobile gear will be set or towed close enough to interact with the scour protection surrounding each foundation, in the interest of vessel safety procedures • SouthCoast Wind will work with fishermen through a gear loss claim application form to determine if reimbursement is warranted in a process similar to the compensation application process already in place for potential gear loss due to geophysical and geotechnical survey activity • SouthCoast Wind has conducted a Cable Burial Risk Assessment to calculate the target cable lowering depth to minimize risks to the offshore export cables from damage, and to mitigate potential conflicts	Commercial and Recreational Fishing	BSEE

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		between commercial or recreational fishermen and the new structure • To minimize conflicts between fishing gear and the proposed Project's inter-array and offshore export cables, the inter-array cables will be buried at a target depth of 3.2 to 8.2 feet (1.0 to 2.5 meters), and the offshore export cables will be buried at a target depth of 3.2 to 13.1 feet (1.0 to 4.0 meters) • To minimize interference with fishing activities, SouthCoast Wind has sited the export cable corridors to minimize overlap with known areas of high fishing activity • Long-term monitoring of cable burial depth and condition will serve as another mitigation strategy, ensuring appropriate burial depth is maintained during the O&M phase • Where applicable, SouthCoast Wind will record required cable protection on electronic charts to be distributed to fishermen		
Construction, Decommissioning	Change in zoning exception or relief for the installation of the landing location landfall site and onshore substation	• SouthCoast Wind will work with the local authorities and MA EFSB and RI ESFB to facilitate the authorization of the required land use	Zoning and Land Use	Best practice - not an enforceable measure
Construction, Decommissioning	**Construction Areas and Vehicle Traffic** Accessibility disruption of neighboring land uses	• SouthCoast Wind will develop and implement a Traffic Management Plan prior to construction to minimize disruptions to residences and commercial establishments in the vicinity of onshore construction activities; pedestrian and bicycle safety and movement would also be addressed to minimize effects of construction • SouthCoast Wind will develop and implement a Construction Management Plan, including an onshore construction schedule, in consultation with the local	Zoning and Land Use	BOEM, MassDEP and RIDEM

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		authorities and relevant stakeholders to minimize effects on neighboring land uses to the extent feasible • SouthCoast Wind will coordinate with stakeholders to schedule work activities outside of major events taking place onshore • SouthCoast Wind will ensure that onshore construction activities comply with local regulatory authority requirements		
Construction, Decommissioning	Reduced enjoyment of neighboring land uses due to noise, vibration, and fugitive dust	• SouthCoast Wind will implement BMPs throughout the proposed Project phases to minimize potential effects • SouthCoast Wind will develop and implement an onshore construction schedule to minimize effects on neighboring land uses to the extent feasible • SouthCoast Wind will ensure that onshore construction activities comply with local regulatory authority requirements	Zoning and Land Use	Best practice - not an enforceable measure
Construction, Decommissioning	Disruption of use due to accidental releases	• SouthCoast Wind will implement BMPs throughout the proposed Project phases to minimize potential effects • SouthCoast Wind will follow the approved SMS and OSRP to avoid, control, and address any accidental releases during all proposed Project activities	Zoning and Land Use	Best practice - not an enforceable measure
O&M	Reduced enjoyment of neighboring land uses due to noise, vibration, and fugitive dust	• SouthCoast Wind will implement best practices throughout the proposed Project phases to minimize potential effects • SouthCoast Wind will develop and implement an onshore construction schedule to minimize effects on neighboring land uses to the extent feasible • SouthCoast Wind will ensure that onshore construction activities comply with local regulatory authority requirements	Zoning and Land Use	Best practice - not an enforceable measure

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
O&M	Accessibility disruption of neighboring land uses due to construction areas and vehicle traffic	• If unscheduled repairs are required, SouthCoast Wind will obtain an authorization from the local authorities as required • SouthCoast Wind will coordinate with stakeholders to schedule unscheduled repairs outside of major events taking place onshore, to the extent possible • SouthCoast Wind will ensure that unscheduled repairs comply with local regulatory authority requirements	Zoning and Land Use	Best practice - not an enforceable measure
O&M	Disruption of use due to accidental events	• SouthCoast Wind will implement best practices throughout the proposed Project phases to minimize potential effects • SouthCoast Wind will develop and implement an emergency response procedure to avoid, control and address any accidental releases during all proposed Project activities	Zoning and Land Use	Best practice - not an enforceable measure
Construction	**Actions that may Displace Human Uses/ Activities that may Displace or Impact Fishing and Recreation and Tourism/Accidental Events/ Altered Visual Conditions** Vessel operations and presence of offshore equipment	• SouthCoast Wind will coordinate directly with the USCG in response to distress/Search and Rescue events • SouthCoast Wind will post LNMs on the SouthCoast Wind website • SouthCoast Wind will submit LNMs to the USCG and Fleet Command prior to the commencement of offshore construction activities • SouthCoast Wind will implement construction safety zones in consultation with USCG and communicate to local mariners regarding upcoming and ongoing construction activities. • SouthCoast Wind will utilize on-scene safety vessel(s) and/or personnel to advise mariners of construction activity, as necessary • SouthCoast Wind will investigate means to update navigation charts with NOAA to improve communications for on-water activities	Navigation and Vessel Traffic	USCG

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• SouthCoast Wind will comply with regulatory requirements • SouthCoast Wind will utilize on-scene safety vessel(s) and/or personnel to advise mariners of construction activity, as necessary		
Construction	**Change in Ambient Lighting** Construction lighting	• SouthCoast Wind will utilize on-scene safety vessel(s) and/or personnel to advise mariners of construction activity, as necessary	Navigation and Vessel Traffic	Best practice - not an enforceable measure
O&M	**Actions that may Displace Human Uses/ Activities that may Displace or Impact Fishing and Recreation and Tourism/Accidental Events/ Altered Visual Conditions** Vessel operations and presence of structures	• SouthCoast Wind will coordinate directly with the USCG in response to distress/Search and Rescue events • Mariner diligence and offshore standard work safety practices will be established for all Project-related vessels • SouthCoast Wind will adopt best practice of an east-west orientation in the Lease Area with 1 nm (1.9 km) spacing between WTG/OSP rows. Layout orientation aligns with neighboring lease holders to provide fishermen consistent navigable routes to fishing grounds	Navigation and Vessel Traffic	Best practice - not an enforceable measure
O&M	**Actions that may Displace Human Uses/ Activities that may Displace or Impact Fishing and Recreation and Tourism/Accidental Events/ Altered Visual Conditions** Vessel operations and presence of structures	• SouthCoast Wind will include lighting and marking of offshore proposed Project structures according to permit requirements • Marking of structures will be aligned with letter and number marking of all offshore structures within the MA/RI WEA, improving SAR and general navigation • SouthCoast Wind will maintain the Project's distance from the established Traffic Separation Scheme	Navigation and Vessel Traffic	BOEM, BSEE, USCG
O&M	**Changes in Ambient Lighting** Lighting of offshore structures	• SouthCoast Wind will submit requests for PATON permits from the USCG that consider a range of issues related to navigational safety	Navigation and Vessel Traffic	USCG

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
Decommissioning	**Accidental Events** Vessel operations	• SouthCoast Wind will utilize on-scene safety vessel(s) and/or personnel to advise mariners of decommissioning activity, as necessary	Navigation and Vessel Traffic	Best practice - not an enforceable measure
Decommissioning	**Actions that may Displace Human Uses/ Activities that may Displace or Impact Fishing and Recreation and Tourism/Accidental Events/ Altered Visual Conditions** Presence of offshore equipment	• SouthCoast Wind will coordinate directly with the USCG in response to distress/Search and Rescue events • SouthCoast Wind will utilize on-scene safety vessel(s) and/or personnel to advise mariners of decommissioning activity, as necessary	Navigation and Vessel Traffic	Best practice - not an enforceable measure
Decommissioning	**Changes in Ambient Lighting** Decommissioning equipment lighting	• SouthCoast Wind will utilize on-scene safety vessel(s) and/or personnel to advise mariners of decommissioning activity, as necessary	Navigation and Vessel Traffic	Best practice - not an enforceable measure
Construction, O&M, Decommissioning	**Changes in Ambient Lighting** Introduced lighting	• SouthCoast Wind will comply with USCG, BOEM and FAA marking and lighting guidelines • SouthCoast Wind will utilize PATONs approved by USCG and installed in accordance with IALA Guidance (IALA, 2013) for the marking of man-made offshore structures • SouthCoast Wind will ensure marking of structures will be aligned with letter and number marking of all offshore structures within the MA/RI WEA, improving SAR and general navigation • SouthCoast Wind will coordinate with the USCG, Air Force, Navy, NORAD, and other military and national security stakeholders to implement operational curtailment of WTGs during search and rescue operations, or other national security emergencies, near the Lease Area, as necessary • SouthCoast Wind will avoid, minimize, or mitigate effects on navigation by equipping all Project-related	Other Marine Uses	BOEM, BSEE, USCG

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		vessels and relevant infrastructure with the required navigation marking and lighting and day shapes		
Construction, O&M, Decommissioning	**Installation and Maintenance of Infrastructure** Increased marine/vessel traffic and damage to existing cables/pipelines	• SouthCoast Wind will use well established standard techniques for adequately protecting existing and newly installed cables • SouthCoast Wind will develop cable crossing specifics in consultation with the cable owners as proposed Project planning continues • SouthCoast Wind will utilize on-scene safety vessel(s) and/or personnel to advise mariners of construction/ decommissioning activity, as necessary • SouthCoast Wind will investigate means to update navigation charts with NOAA to improve communications for on-water activities • SouthCoast Wind will establish mariner diligence and offshore standard work safety practices for all Project-related vessels	Other Marine Uses	Best practice - not an enforceable measure
Construction, O&M, Decommissioning	**Presence of Infrastructure** Obstruction to air navigation, and interference with radar systems	• SouthCoast Wind will work with the FAA and the owner/operator of any affected systems to ensure that appropriate mitigation measures are identified and implemented • SouthCoast Wind will use ADLS to reduce visual effects • SouthCoast Wind will coordinate with the DoD Siting Clearinghouse, FAA, and NORAD to determine potential effects on radars and NAVAIDS and identify appropriate mitigation measures • SouthCoast Wind will coordinate with NOAA and the Northeastern Regional Association of Coastal Ocean Observing Systems to determine potential effects on high-frequency radars and identify appropriate mitigation measures, as necessary	Other Marine Uses	Best practice - not an enforceable measure

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
O&M	**Installation and Maintenance of Infrastructure/Presence of Infrastructure** Use conflicts—military	• SouthCoast Wind will provide a 1 nm (1.9 km) space between offshore structures (WTGs and OSPs) providing room for anticipated vessels to transit through and safely maneuver within the proposed Offshore Project Area • SouthCoast Wind will align marking of structures with letter and number marking of all offshore structures within the MA/RI WEA, improving SAR and general navigation • SouthCoast Wind will liaise with the military and national security stakeholders to reduce potential conflicts. • SouthCoast Wind will ensure mariner diligence and offshore standard work safety practices are established for all Project-related vessels	Other Marine Uses	BOEM, BSEE, and USCG
Construction	**Unplanned Events** Allisions and collisions, unplanned releases, and occupational hazards	• SouthCoast Wind will operate under an approved SMS • SouthCoast Wind will utilize on-scene safety vessel(s) and/or personnel to advise mariners of decommissioning activity, as necessary • SouthCoast Wind will investigate means to update navigation charts with NOAA to improve communications for on-water activities • SouthCoast Wind will develop and implement an onshore Traffic Management Plan prior to construction to address vehicular, bicycle, and pedestrian safety • SouthCoast Wind will ensure onshore work would also be planned to be performed primarily off-season when there are fewer people in the area • SouthCoast Wind will operate under an approved OSRP that details prevention and control measures of unplanned releases in the Project Area • SouthCoast Wind will ensure Project Vessels will adhere to USCG regulations surrounding planned and unplanned discharges	Public Health and Safety	BOEM, USCG, MassDEP and RIDEM

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• SouthCoast Wind will prepare and submit an SWPPP for onshore construction activities before start of construction		
O&M	**Unplanned Events** Allisions and collisions, unplanned releases, and occupational hazards	• SouthCoast Wind will maintain the northeast approach Traffic Separation Scheme • Mariner diligence and offshore standard work safety practices will be established for all Project-related vessels • SouthCoast Wind will adopt best practice of an east-west orientation in the Lease Area with 1 nm (1.9 km) spacing between WTG/OSP rows. Layout orientation aligns with neighboring lease holders to provide fishermen consistent navigable routes to fishing grounds • SouthCoast Wind will include lighting and marking of offshore proposed Project structures according to permit requirements • Marking of structures will be aligned with letter and number marking of all offshore structures within the MA/RI WEA, improving SAR and general navigation. • In the event that scheduled or unscheduled repairs are required that would impede onshore traffic flow, an authorization will be obtained from the local authorities as required. • SouthCoast Wind will follow measures prescribed and detailed in the approved SMS and OSRP • SouthCoast Wind will operate under an approved OSRP that details prevention and control measures of unplanned releases in the Project Area • Project Vessels will adhere to USCG regulations surrounding planned and unplanned discharges	Public Health and Safety	BOEM, BSEE, USCG, MassDEP and RIDEM

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
Applicant-Proposed Measures from COP Appendix O, SouthCoast Wind Marine Mammal and Sea Turtle Monitoring and Mitigation Plan (SouthCoast Wind 2024)				
PSO and Acoustic PSO (PAM Operator) Training, Experience and Responsibilities				
Construction	**Observer qualifications and training**	• PSOs and Acoustic PSOs (APSO / PAM Operators) will have met NMFS and BOEM training and experience requirements. • PSOs and APSOs will be employed by a third-party observer provider. Briefings between construction supervisors and crews and the PSO/APSO team will be held prior to the start of all pile driving activities, as well as when new personnel join the vessel(s). • At least one PSO on duty at all times will have prior experience working as a PSO. • APSOs responsible for determining if an acoustic detection originated from a NARW will be trained in identification of mysticete vocalizations.	Marine Mammals and Sea Turtles	BOEM, BSEE, and NMFS
	Responsibilities and authorities of PSOs	• PSOs will have no other responsibilities while on watch. • Any PSO or APSO on duty will have the authority to delay the start of operations or to call for a shutdown based on their observations or acoustic detection. • A clear line and method of communication between the PSOs/APSOs and pile-driving crew will be established and maintained to ensure mitigation measures are conveyed without delay.		
Visual Monitoring				
Construction	**Number of PSOs**	• A sufficient number of PSOs will be stationed aboard the installation and/or nearby support vessels to meet the following criteria: ○ At least two PSOs on duty during all pre-clearance periods and active pile driving; - At least one PSO on duty during all other daylight periods.	Marine Mammals and Sea Turtles	BOEM, BSEE, and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		○ A maximum of four consecutive hours on watch per PSO. ○ A maximum of 12 hours on watch during a 24-hour period.		
	Visual monitoring methods	• Observations will be conducted from the best safe vantage point(s) on the construction or nearby support vessel to ensure visibility of the clearance zones. • When conducting observations during pile driving, PSOs will scan systematically with the unaided eye, high magnification (25x) binoculars, and/or standard handheld (7x) binoculars to search continuously for marine mammals during all observational periods. • When monitoring at night, PSOs will monitor for marine mammals and other protected species using night-vision goggles with thermal clip-ons and a hand-held spotlight. • PSOs will watch for and record all marine mammal sightings regardless of the distance from the observer and/or sound source. • Distances to observed animals will be estimated with range finders, reticule binoculars, or clinometers when possible and based on the best estimate of the PSO when necessary. • PSOs will record watch effort and environmental conditions on a routine basis.		
	Visual monitoring during vessel transit	• PSOs and/or trained vessel crew will observe for marine mammals and sea turtles at all times when vessels are transiting to/from and in the Project Area and port. • PSOs and/or vessel crew will request ship-strike avoidance measures if necessary (see below).		
Acoustic Monitoring				

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
Construction	**Number of APSOs**	• At least one APSO during all pre-clearance periods and active pile driving. • A maximum of 4 consecutive hours on watch per APSO. • A maximum of 12 hours of watch time per 24-hour period per APSO.	Marine Mammals and Sea Turtles	BOEM, BSEE, and NMFS
	Passive acoustic monitoring methods	• A real-time PAM system will be used to supplement visual monitoring during pre-piling clearance and throughout pile driving. • Use of PAM will allow initiation of pile driving when visual observation of the entire clearance zone is not possible due to poor visibility, including darkness. • A detailed description of the real-time PAM system will be developed during the Marine Mammal Protection Act Incidental Take Authorization process. • The PAM system may not be located on the pile-installation vessel to reduce masking of marine mammals sounds. • The APSOs will immediately communicate all acoustic detections of marine mammals to PSOs performing visual observations including any determination regarding species identification, distance, and bearing of the marine mammal.		
	Sound source verification	• A detailed plan for Sound Source Verification will be developed during the Marine Mammal Protection Act Incidental Take Authorization process. • Components of the plan will likely include: ○ Measurements of the largest of each pile type (monopiles and/or jacket piles) to be installed with and without noise attenuating systems to quantify the effectiveness of the system(s). ○ Measurements will be taken at distances designed to verify modeled distances to Level A and Level B		

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		thresholds and/or other mitigation action distances. ○ Measurement results will be used to modify, if necessary, distances to Level A and Level B thresholds and estimate effects in a post-construction monitoring report.		
Clearance Zones				
Construction	**Clearance zones for protected species**	• Because of the low probability of a long-term exposure event and for practical implementation reasons, it is anticipated that the Clearance Zones will be similar to those listed below, with the final distances to be determined during the MMPA ITA application process: • North Atlantic Right Whale: 1 km; - Mysticete whales (low-frequency cetaceans): 0.5 km; - Harbor porpoise (high-frequency cetaceans): 0.12 km; - All other marine mammals (mid-frequency cetaceans and pinnipeds): 0.05 km; and - Sea Turtles: 0.05 km.	Marine Mammals and Sea Turtles	BOEM, BSEE, and NMFS
Pre-start Clearance				
Construction	**Pre-start clearance**	• Prior to the beginning of each pile driving event, PSOs and APSOs will monitor for marine mammals and sea turtles for a minimum of 30 minutes and continue at all times during pile driving. • If a marine mammal is detected within or approaching the shutdown zone (via visual observation or PAM) during the preclearance period, pile driving will not begin until the animal(s) is confirmed to have exited the relevant shutdown zone, or until an additional time period has elapsed with no further sighting of the animal. • Additional time period will be 15 minutes for odontocetes and pinnipeds and 30 minutes for mysticetes and sea turtles.	Marine Mammals and Sea Turtles	BOEM, BSEE, and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
Soft-Start				
Construction	**Soft-start**	• Soft-start procedures will be followed, to the extent practicable, at the beginning of each pile driving event or any time pile driving has stopped for longer than 30 minutes. • If a marine mammal is detected within or about to enter the shutdown zone during the soft-start procedure, pile driving will be delayed and measures will be followed as stated in Section 7.	Marine Mammals and Sea Turtles	BOEM, BSEE, and NMFS
Shutdowns				
Construction	**Shutdowns**	• PSOs or APSOs will request a shutdown of pile driving if a marine mammal or sea turtle is detected within or about to enter the applicable shutdown zone for that species (see Section 4). • If a shutdown is not feasible at that time in the installation process because of a risk to human or vessel safety or the risk of jeopardizing the installation process, a reduction in the hammer energy of the greatest extent possible will be considered and implemented. • Following shutdown, pile driving will restart using the same procedure described above during pre-start clearance.	Marine Mammals and Sea Turtles	BOEM, BSEE, and NMFS
Potential Additional Measure to Protect North Atlantic Right Whale				
Construction	**NARW protection measures**	• By concentrating construction activities when NARW are less likely to be present in the region (May 1 through December 31), including the Lease Area, the amount of activity to occur when more NARW are likely to be present can be reduced, thereby reducing the total potential impacts on NARW.	Marine Mammals and Sea Turtles	BOEM, BSEE, and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• To accomplish this, SouthCoast Wind will propose additional monitoring and mitigation measures to support the start (or continuation) of pile driving at night or in poor visibility conditions during the period when NARW are less likely to be present. • Specific monitoring tools and plans will be developed as a part of the MMPA ITA process, but may include the use of advanced infrared systems, real-time PAM, autonomous underwater vehicles, autonomous aerial vehicles, or other advanced technologies.		
Vessel Strike Avoidance				
Construction	**General measures**	• A minimum of one PSO or trained vessel crew will be present on all vessels when transiting. • Observers will maintain a vigilant watch for all marine mammals and slow down or stop vessels to avoid striking protected species. • Monitoring the NMFS NARW reporting systems from November 1 through May 30 and whenever a DMA is established in the operational area.	Marine Mammals and Sea Turtles	BOEM, BSEE, and NMFS
	Separation distances	• Maintaining >500-meter distance from any sighted NARW or an unidentified large marine mammal. • Maintaining >100-meter from all ESA-listed whales or humpback whales. • Maintaining >50 meters from all other marine mammals, with the exception of delphinids and pinnipeds that approach the vessel, in which case the vessel operator must avoid excessive speed or abrupt changes in direction		
	Actions given observed marine mammal	• If underway, vessels will steer a course away from any NARW at 10 kts or less until the 500-meter minimum separation distance has been established.		

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		• If a NARW comes within 100 meters, then the vessel will reduce speed and shift the engines into neutral, if safe to do so. The vessel will not engage engines until the NARW has moved beyond 100 meters, in which case, any vessel will steer a course away from the animal at 10 knots or less until the 500-meter minimum separation distance has been established. • If the vessel is stationary, the vessel will not engage engines until the NARW has moved beyond 100 meters, in which case any vessel will steer a course away from the animal at 10 knots or less until the 500-meter minimum separation distance has been established. • Report sightings of all dead or injured marine mammals or sea turtles within 24 hours.		
	Speed reduction	• Reducing speed of all vessels, except CTVs, to ≤10 knots between November 1 through May 30. • From November 1 through May 30, CTVs may travel at over 10 knots. However, if a NARW is detected via visual observation within or approaching the transit route, all CTVs will travel at 10 knots or less for the remainder of that day. • Operating vessels, except CTVs, will travel at speeds ≤10 knots in any DMA. • Reducing vessel speeds to ≤10 knots when mother/calf pairs, pods, or large assemblages of marine mammals are observed. • Complying with speed restrictions (≤10 knots) in NARW management areas including SMAs and active DMAs, except as noted previously for CTVs.		
Reporting Dead or Injured Marine Mammals				
Construction, O&M, Decommissioning	**Actions given a marine mammal is**	• The activity(ies) resulting in the injury/death will be stopped immediately.	Marine Mammals and Sea Turtles	BOEM, BSEE, and NMFS

Project Phase	Impact Producing Factors Potential Effect or Category	Description	Resource Area Mitigated	Anticipated Enforcing Agency
	taken in a prohibited manner by construction activities	• The incident will be reported to the NMFS Office of Protected Resources and the NMFS New England Stranding Network Coordinator. • The report will include all available information required by the IHA or the NMFS stranding report form. • SouthCoast Wind will not resume the activity which resulted in the injury until NMFS is able to review the circumstances of the prohibited take and authorize resumption of the activity(ies).		
	Actions given an unknown and recent observed dead or injured marine mammal	• SouthCoast Wind will immediately report the incident to the NMFS Office of Protected Resources and the NMFS New England Stranding Network Coordinator. • The report will include the same information identified for a take by construction activity. • Activities will continue while NMFS reviews the circumstances of the incident and works with SouthCoast Wind to determine whether modifications to the activities are appropriate.		
	Actions given observation of a dead or injured marine mammal not associated with or related to construction activities	• SouthCoast Wind will report the incident to the NMFS Office of Protected Resources and the NMFS New England Stranding Network Coordinator, within 24 hours of the discovery. • SouthCoast Wind will include any documentation of the stranded animal sighting to NMFS and the Marine Mammal Stranding Network including photographs and video footage if available. • Construction activity may continue.		

ACHP = Advisory Council on Historic Preservation; ADLS = Aircraft Detection Lighting System; APSO = acoustic protected species observer; ASLF = ancient submerged landform feature; BMP = best management practice; BOEM = Bureau of Ocean Energy Management; BSEE = Bureau of Safety and Environmental Enforcement; BUAR = Board of Underwater Archaeological Resources; CFR = code of federal regulation; COP = Construction and Operations Plan; CRC = cultural resource consultant; CTV = crew transfer vessel; DMA = dynamic management area; DP = dynamic positioning; EFH = essential fish habitat; EJ = environmental justice; EMF = electromagnetic fields; EPA = Environmental Protection Agency; ESA = Endangered Species Act; FAA = Federal Aviation Administration; FLO = fisheries liaison officer; FR = fisheries representative; HDD = horizontal directional drilling; HRG = high-resolution geophysical; HVDC = high-voltage direct current; IALA = International Association of Marine Aids to Navigation and Lighthouse

G.2 Agency-Proposed Mitigation Measures

Table G-2 identifies agency-proposed mitigation measures that have been proposed to mitigate and/or monitor potential impacts from the Project. The paragraphs below provide additional information regarding the mitigation measures.

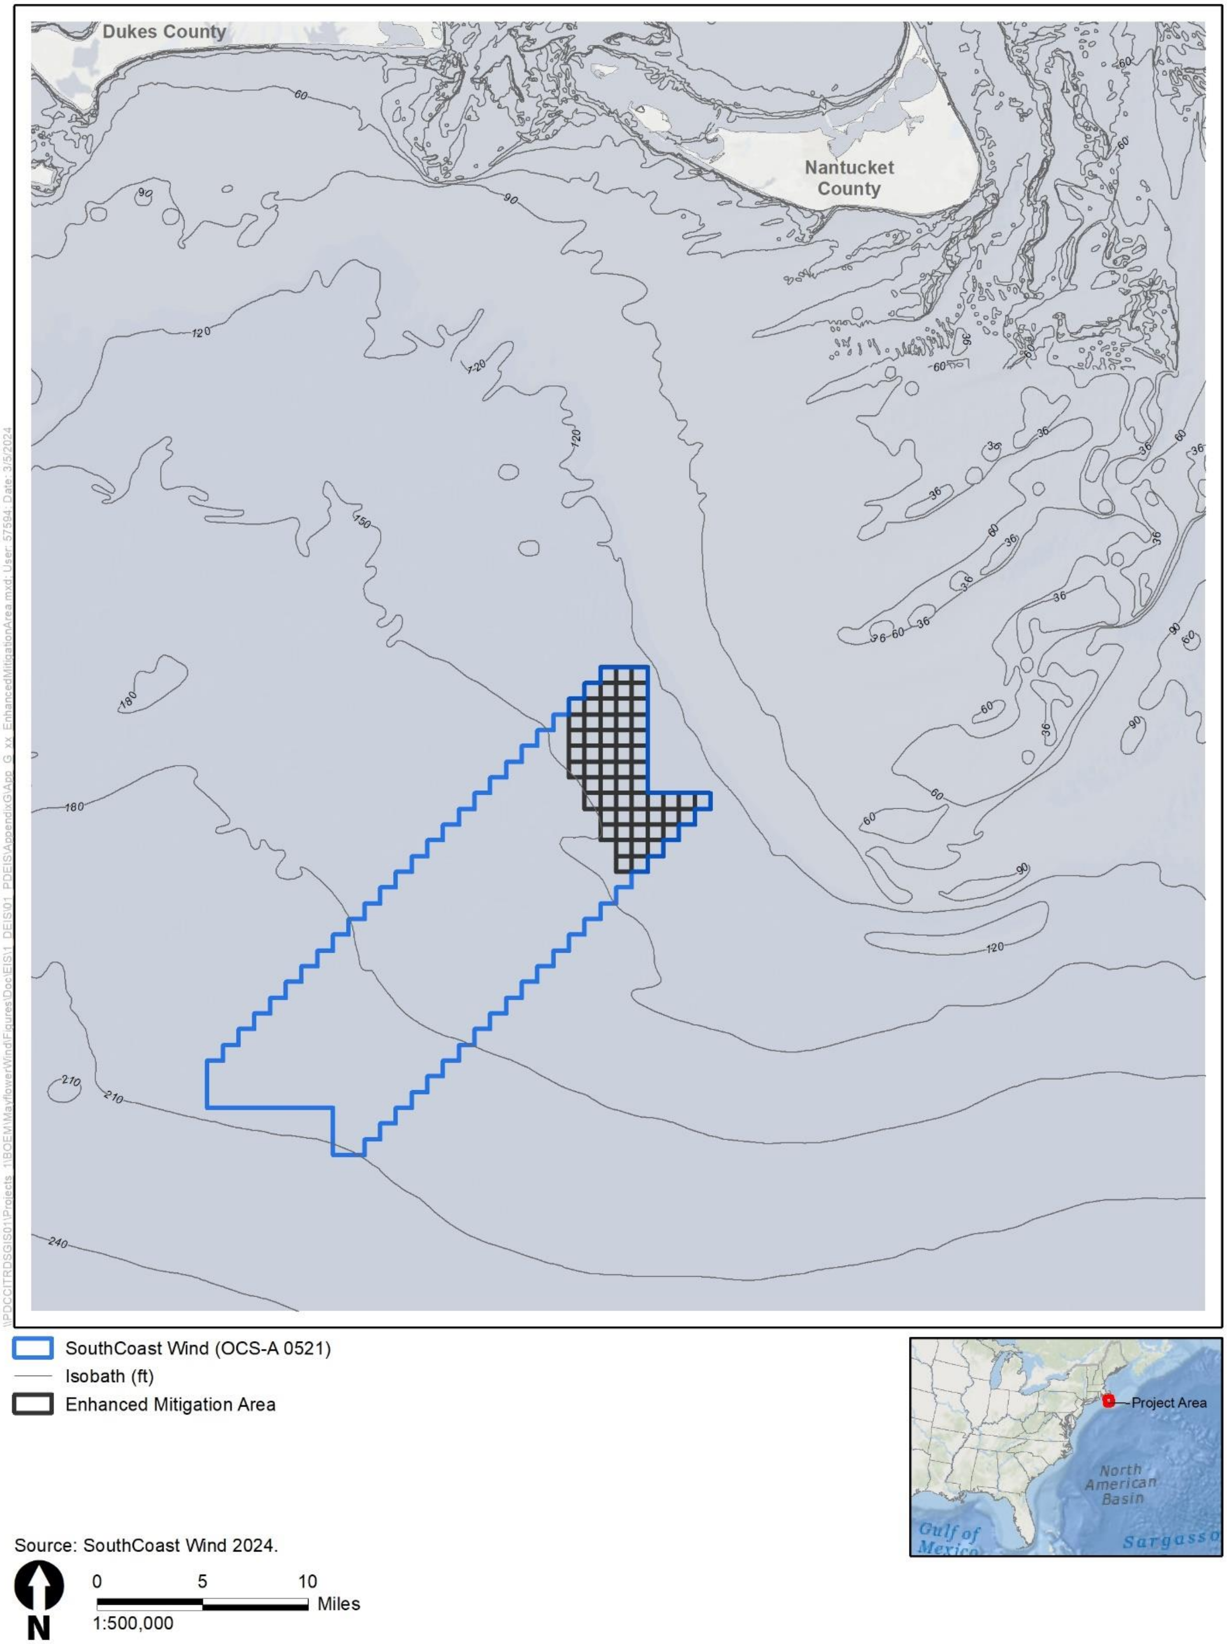

Figure G-1. SouthCoast Wind enhanced mitigation area

Table G-2. Mitigation and monitoring measures resulting from consultations

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
NHPA Section 106 Mitigation Measures from the Memorandum of Agreement					
CUL-1	Pre-C, C, O&M, D	Compliance with Section 106 Memorandum of Agreement	The Lessee will comply with stipulations of the *Memorandum of Agreement Among the Bureau of Ocean Energy Management, Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, Wampanoag Tribe Of Gay Head (Aquinnah), The State Historic Preservation Officers of Massachusetts and Rhode Island, Southcoast Wind Energy LLC, and The Advisory Council on Historic Preservation Regarding the SouthCoast Wind Project* (hereafter referred to as the MOA) as developed by BOEM through NHPA Section 106 consultations with federally recognized Tribes, Massachusetts and Rhode Island SHPOs, ACHP, and consulting parties to resolve adverse effects on historic properties. As defined in the Section 106 regulations, consulting parties include those who are property owners of or have demonstrated interest in the historic properties BOEM has determined would be adversely affected by the Project.	Cultural	BOEM, BSEE, Massachusetts Historical Commission, Massachusetts Board of Underwater Archaeological Resources, Rhode Island Historical Preservation & Heritage Commission
CUL-2	C	Avoidance of Adverse Effects on Historic Properties in Marine Area of Potential Effect	Per MOA Stipulation I.A.1, the Lessee will comply with protective buffers recommended by the Qualified Marine Archaeologist (QMA) for 31 identified marine archaeological resources and seven ASLFs to avoid adverse effects on these historic properties in the marine APE.	Cultural	BOEM, BSEE, Massachusetts Historical Commission, Massachusetts Board of Underwater Archaeological Resources, Rhode Island Historical Preservation & Heritage Commission
CUL-3	C	Funding and Implementation of Historic Properties Treatment Plan for Historic Properties in the Marine Area of Potential Effects	Per MOA Stipulation III.C.1 and the associated HPTP (MOA, Attachment 8), the Lessee will implement the measures described in the HPTP and fund these measures per the agreed-upon amounts in *Mitigation Funding Amounts* (MOA, Attachment 5) to resolve adverse effects on historic properties in the marine APE.	Cultural	BOEM, BSEE, Massachusetts Historical Commission, Massachusetts Board of Underwater Archaeological Resources, Rhode Island Historical Preservation & Heritage Commission
CUL-4	Pre-C, C, O&M, D	Marine Archaeology Post-Review Discovery Plan	Per MOA Stipulation XI, if historic properties are discovered that may be historically significant or unanticipated effects on historic properties are found, or in the event of a post-review discovery of a historic property or unanticipated effects on a historic property prior to or during construction, installation, O&M, or decommissioning of the Project, the Lessee will implement the actions described in the post-review discovery plan (PRDP) for marine archaeology (MOA, Attachment 13).	Cultural	BOEM, BSEE, Massachusetts Historical Commission, Board of Underwater Archaeological Resources, Rhode Island Historical Preservation & Heritage Commission
CUL-5	C	Archaeological Monitoring in the Terrestrial Area of Potential Effects	Per MOA Stipulation I.A.2, the Lessee will implement a construction monitoring program consistent with the monitoring plan for terrestrial archaeology (MOA, Attachments 3 and 4).	Cultural	BOEM, BSEE, Massachusetts Historical Commission, Rhode Island Historical Preservation & Heritage Commission
CUL-6	C	Funding and Implementation of Historic Properties Treatment Plans for Historic Properties in the Terrestrial Area of Potential Effects	Per MOA Stipulation III.D.1 and the associated HPTP (MOA, Attachment 7), the Lessee will implement the measures described in the HPTP and fund these measures per the agreed-upon amounts in *Mitigation Funding Amounts* (MOA, Attachment 5) to resolve adverse effects on historic properties in the terrestrial APE.	Cultural	BOEM, BSEE, Massachusetts Historical Commission, Rhode Island Historical Preservation & Heritage Commission

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
CUL-7	Pre-C, C, O&M, D	Terrestrial Archaeology Post-Review Discovery Plan	Per MOA Stipulation XI, if historic properties are discovered that may be historically significant or unanticipated effects on historic properties are found, or in the event of a post-review discovery of a historic property or unanticipated effects on a historic property prior to or during construction, installation, O&M, or decommissioning of the Project, the Lessee will implement the actions described in the PRDP for terrestrial archaeology (MOA, Attachment 14).	Cultural	BOEM, BSEE, Massachusetts Historical Commission, Rhode Island Historical Preservation & Heritage Commission
CUL-8	C, O&M	Minimization of Adverse Effects on Historic Properties in the Visual Area of Potential Effects	Per MOA Stipulation II.A, the Lessee will implement measures for minimizing adverse effects on historic properties in the visual APE to decrease visual clutter, reduce visual contrast, and reduce light intrusion.	Cultural	BOEM, BSEE, Massachusetts Historical Commission, Rhode Island Historical Preservation & Heritage Commission
CUL-9	C	Funding and Implementation of Historic Properties Treatment Plans for Historic Properties in the Visual Area of Potential Effects	Per MOA Stipulation III.C.1 and the associated HPTPs (MOA, Attachments 8–11), the Lessee will implement the measures described in these HPTPs and fund these measures per the agreed-upon amounts in *Mitigation Funding Amounts* (MOA, Attachment 5) to resolve adverse effects on historic properties in the visual APE.	Cultural	BOEM, BSEE, Massachusetts Historical Commission, Rhode Island Historical Preservation & Heritage Commission
Measures included in BOEM's NMFS BA that are Part of the Proposed Action for ESA Consultation (October 2024)					
BA-1	C	LOA Requirements	The measures required by the final MMPA LOA for Incidental Take Regulations would be incorporated into COP approval.	Marine Mammals	BOEM and BSEE
BA-2	C, O&M, D	Geophysical Surveys and ESA Species	SouthCoast Wind must comply with all the Project Design Criteria and Best Management Practices for Protected Species from the documents "Project Design Criteria and Best Management Practices for Protected Species Associated with Offshore Wind Data Collection" and "Offshore Wind Site Assessment and Site Characterization Activities Programmatic Consultation" that implement the integrated requirements for threatened and endangered species in the June 29, 2021, programmatic consultation under the ESA (revised November 22, 2021), as well as the June 29, 2021, NMFS Letter of Concurrence (LoC).	Marine Mammals, Sea Turtles, ESA-Listed Species	BOEM and BSEE
BA-4	C, O&M, D	Protected Species Detection and Vessel Strike Avoidance: Vessel Crew and Visual Observer Training Requirements	The Lessee must provide Project-specific training to all vessel crew members, Visual Observers, and Trained Lookouts on the identification of sea turtles and marine mammals, vessel strike avoidance and reporting protocols, and the associated regulations for avoiding vessel collisions with protected species. Reference materials for identifying sea turtles and marine mammals must be available aboard all Project vessels. Confirmation of the training and understanding of the requirements must be documented on a training course log sheet, and the Lessee must provide the log sheets to DOI upon request. The Lessee must communicate to all crew members its expectation for them to report sightings of sea turtles and marine mammals to the designated vessel contacts. The Lessee must communicate the process for reporting sea turtles and marine mammals (including live, entangled, and dead individuals) to the designated vessel contact and all crew members. The Lessee must post the reporting instructions including communication channels in highly visible locations aboard all Project vessels.	Marine Mammals, Sea Turtles	BOEM
BA-5	C, O&M, D	Protected Species Detection and Vessel Strike Avoidance: Vessel Observer Requirements	The Lessee must ensure that vessel operators and crew members maintain a vigilant watch for marine mammals and sea turtles, and reduce vessel speed, alter the vessel's course, or stop the vessel as necessary to avoid striking marine mammals or sea turtles. All vessels transiting to and from the SouthCoast Wind farm must have a trained lookout for NARWs on duty at all times, during which the trained lookout must monitor a vessel strike avoidance zone around the vessel. The trained lookout must maintain a vigilant watch at all times a vessel is underway, and when technically feasible, be capable of monitoring the 500-meter Vessel Strike Avoidance Zone for ESA-listed species and to maintain minimum separation distances. Alternative monitoring technology (e.g., night vision, thermal cameras) must be available to maintain a vigilant watch at night and in any other low visibility conditions. If a vessel is carrying a trained lookout for the purposes of maintaining watch for NARWs, a trained lookout for sea turtles is not required, provided that the trained lookout maintains watch for marine mammals and sea turtles. If the trained lookout is a vessel crew member, the lookout obligations, as noted above, must be that person's designated role and primary responsibility while the vessel is transiting. Vessel personnel must be provided an Atlantic reference guide to help identify marine mammals and sea turtles that may be encountered. Vessel personnel must also be provided material regarding NARW Seasonal Management Areas (SMAs), Dynamic Management Areas (DMAs), and Slow Zones, sightings information, and reporting. All observations must be recorded per reporting requirements.	Marine Mammals, Sea Turtles	BOEM

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			Outside of active watch duty, members of the monitoring team must check NMFS Right Whale Sighting Advisory System (RWSAS) for the presence of NARWs in the SouthCoast Wind farm. The trained lookout must check https://seaturtlesightings.org before each trip and report any detections of sea turtles in the vicinity of the planned transit to all vessel operators or captains and lookouts on duty that day. For all vessels operating north of the Virginia/North Carolina border, between June 1 and November 30, the Lessee must have a trained lookout posted on all vessel transits during all phases of the Project to observe for sea turtles. For all vessels operating south of the Virginia/North Carolina border, year-round, the Lessee must have a trained lookout posted on all vessel transits during all phases of the Project to observe for sea turtles. The trained lookout will communicate any sightings in real time to the captain to implement required avoidance measures.		
BA-6	Pre-C, C, O&M, D	Protected Species Detection and Vessel Strike Avoidance: Communication of Threatened and Endangered Species Sightings	The Lessee must ensure that whenever multiple Project vessels are operating, any visual detections of ESA-listed species (marine mammals and sea turtles) are communicated in near real time to a third-party Protected Species Observer (PSO), vessel captains, or both associated with other Project vessels.	Marine Mammals, Sea Turtles	BOEM
BA-7	C, O&M, D	Protected Species Detection and Vessel Strike Avoidance: Vessel Speed Requirements	Vessel captain and crew must maintain a vigilant watch for all protected species and slow down, stop their vessel, or alter course, as appropriate and regardless of vessel size, to avoid striking any listed species. The presence of a single individual at the surface may indicate the presence of submerged animals in the vicinity; therefore, precautionary measures should always be exercised upon the sighting of a single individual. Vessels underway must not divert their course to approach any protected species. During construction, vessels of all sizes will operate port to port at 10 knots or less between November 1 and April 30 and while operating in the Lease Area, along the export cable route, or transit area to and from ports. Regardless of vessel size, vessel operators must reduce vessel speed to 10 knots (11.5 mph) or less while operating in any Seasonal Management Area (SMA) or visually detected Slow Zones. This requirement does not apply when necessary for the safety of the vessel or crew. Any such events must be reported (see reporting requirements). Otherwise, these speed limits do not apply in areas of Narragansett Bay or Long Island Sound where the presence of NARWs is not expected. The Lessee may only request a waiver from any visually triggered Slow Zone/DMA vessel speed reduction requirements during operations and maintenance, by submitting a vessel strike risk reduction plan that details revised measures and an analysis demonstrating that the measure(s) will provide a level of risk reduction at least equivalent to the vessel speed reduction measure(s) proposed for replacement. The plan included with the request must be provided to NMFS Greater Atlantic Regional Fisheries Office, Protected Resources Division and BOEM at least 90 days prior to the date scheduled for the activities for the waiver is requested. The plan must not be implemented unless NMFS and BOEM reach consensus on the appropriateness of the plan. BOEM encourages increased vigilance through voluntary implementation of best management practices to minimize vessel interactions with NARWs, and by voluntarily reducing speeds to 10 knots or less when operating within an acoustically triggered slow zone, and when feasible, avoid Slow Zones.	Marine Mammals, Sea Turtles	BOEM
BA-8	C, O&M, D	Vessel Strike Avoidance of Large Cetaceans	All vessel operators must check for information regarding mandatory or voluntary ship strike avoidance and daily information regarding NARW sighting locations. These media may include, but are not limited to: NOAA weather radio, U.S. Coast Guard NAVTEX and Channel 16 broadcasts, Notices to Mariners, the Whale Alert app, or WhaleMap website. Information about active SMAs and Slow Zones can be accessed at: https://www.fisheries.noaa.gov/national/endangered-species-conservation/reducing-vessel-strikes-north-atlantic-right-whales If an ESA-listed whale or large unidentified whale is identified within 1,640 feet (500 meters) of the forward path of any vessel (90 degrees port to 90 degrees starboard), the vessel operator must immediately implement strike avoidance measures and steer a course away from the whale at 10 knots (18.5 kilometers per hour) or less until the vessel reaches a 1,640-feet (500 meter) separation distance from the whale. Trained lookouts, visual observers, vessel crew, or PSOs must notify the vessel captain of any whale observed or detected within 1,640 feet (500 meters) of the survey vessel. Upon notification, the vessel captain must immediately implement vessel strike avoidance procedures to maintain a separation distance of 1,640 feet (500 meters) or reduce vessel speed to allow the animal to travel away from the vessel. If a whale is observed but cannot be confirmed as a species other than a NARW, the vessel operator must assume that it is a NARW and execute the required vessel strike avoidance measures to avoid the animal. If an ESA-listed large whale is sighted within 656 feet (200 meters) of the forward path of a vessel, the vessel operator must initiate a full stop by reducing speed and shift the engine to neutral. Engines must not be engaged until the whale has moved outside of the vessel’s path and beyond 1,640 feet (500 meters). If stationary, the vessel must not engage engines until the ESA-listed large whale has moved beyond 1,640 feet (500 meters).	Marine Mammals	BOEM, NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
BA-9	C, O&M, D	Vessel Strike Avoidance of Small Cetaceans and Seals	If pinnipeds or small delphinids of the genera Delphinus, Lagenorhynchus, Stenella, or Tursiops are visually detected approaching the vessel (i.e., to bow ride) or towed equipment, vessel speed reduction, course alteration, and shutdown are not required. For small cetaceans and seals, all vessels must maintain a minimum separation distance of 164 feet (50 meters) to the maximum extent practicable, except when those animals voluntarily approach the vessel. When marine mammals are sighted while a vessel is underway, the vessel operator must endeavor to avoid violating the 164-foot (50-meter) separation distance by attempting to remain parallel to the animal's course and avoiding excessive speed or abrupt changes in vessel direction until the animal has left the area, except when taking such measures would threaten the safety of the vessel or crew. If marine mammals are sighted within the 164-foot separation distance, the vessel operator must reduce vessel speed and shift the engine to neutral, not engaging the engines until animals are beyond 164 feet (50 meters) from the vessel.	Marine Mammals	BOEM
BA-10	C, O&M, D	Vessel Strike Avoidance of Sea Turtles	The Lessee must slow down to 4 knots if a sea turtle is sighted within 328 feet (100 meters) of the operating vessel's forward path. The vessel operator must then proceed away from the turtle at a speed of 4 knots or less until there is a separation distance of at least 328 feet (100 meters) at which time the vessel may resume normal operations. If a sea turtle is sighted within 164 feet (50 meters) of the forward path of the operating vessel, the vessel operator must shift to neutral when safe to do so and then proceed away from the individual at a speed of 4 knots or less until there is a separation distance of at least 328 feet (100 meters), at which time normal vessel operations may be resumed. Between June 1 and November 30, all vessels must avoid transiting through areas of visible jellyfish aggregations or floating vegetation (e.g., *Sargassum* lines or mats). In the event that operational safety prevents avoidance of such areas, vessels must slow to 4 knots while transiting through such areas. All vessel crew members must be briefed on the identification of sea turtles and on regulations and best practices for avoiding vessel collisions. Reference materials must be available aboard all project vessels for identification of sea turtles. The expectation and process for reporting of sea turtles (including live, entangled, and dead individuals) must be clearly communicated and posted in highly visible locations aboard all project vessels, so that there is an expectation for reporting to the designated vessel contact (such as the lookout or the vessel captain), as well as a communication channel and process for crew members to report.	Sea Turtles	BOEM
BA-11	Pre-C, C, O&M, D	Reporting of All NARW Sightings	The Lessee must immediately report all NARWs observed at any time by PSOs or vessel personnel on any Project vessels, during any Project- related activity, or during vessel transit. Reports must be sent to: BOEM (at renewable_reporting@boem.gov) and BSEE (at protectedspecies@bsee.gov); the NOAA Fisheries 24-hour Stranding Hotline number (866-755-6622); the Coast Guard (via Channel 16); and WhaleAlert (through the WhaleAlert app at http://www.whalealert.org/). The report must include the time, location, and number of animals.	Marine Mammals	BOEM
BA-12	Pre-C, C, O&M, D	Detected or Impacted Protected Species Reporting	The Lessee is responsible for reporting dead or injured protected species, regardless of whether they were observed during operations or due to Project activities. The Lessee must report any potential take, strikes, dead, or injured protected species caused by Project vessels or sighting of an injured or dead marine mammal or sea turtle, regardless of the cause, to the NMFS Greater Atlantic Regional Fisheries Office, Protected Resources Division (at nmfs.gar.incidental-take@noaa.gov), NOAA Fisheries 24-hour Stranding Hotline number (866-755-6622), BOEM (at renewable_reporting@boem.gov), and BSEE (at protectedspecies@bsee.gov). Reporting must be as soon as practicable but no later than 24 hours from the time the incident took place (Detected or Impacted Protected Species Report). Staff responding to the hotline call will provide any instructions for the handling or disposing of any injured or dead protected species by individuals authorized to collect, possess, and transport sea turtles. Reports must include at a minimum: (1) survey name and applicable information (e.g., vessel name, station number); (2) GPS coordinates describing the location of the interaction (in decimal degrees); (3) gear type involved (e.g., bottom trawl, gillnet, longline); (4) soak time, gear configuration and any other pertinent gear information; (5) time and date of the interaction; and (6) identification of the animal to the species level. Additionally, the e-mail would transmit a copy of the NMFS Take Report Form and a link to or acknowledgement that a clear photograph or video of the animal was taken (multiple photographs are suggested, including at least one photograph of the head scutes). If reporting within 24 hours is not possible due to distance from shore or lack of ability to communicate via phone, fax, or email, reports would be submitted as soon as possible; late reports would be submitted with an explanation for the delay. At the end of each survey season, a report would be sent to NMFS that compiles all information on any observations and interactions with ESA-listed species. This report would also contain information on all survey activities that took place during the season including location of gear set, duration of soak/trawl, and total effort. The report on survey activities would be comprehensive of all activities, regardless of whether ESA-listed species were observed.	Marine Mammals, Sea Turtles, ESA-Listed Species	BOEM
BA-13	Pre-C, C, O&M, D	Detected or Impacted Dead Non-ESA-Listed Fish	Any occurrence of at least 10 dead non-ESA-listed fish within established shutdown or monitoring zones must also be reported to BOEM (at renewable_reporting@boem.gov) as soon as practicable (taking into account crew and vessel safety), but no later than 24 hours after the sighting.	ESA-Listed Species	BOEM

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
BA-14	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Pile-Driving Time-of-Year Restriction	The Lessee must not conduct any foundation pile-driving activities between December 1 and April 30. Pile driving must not occur in December unless unanticipated delays due to weather or technical problems arise that necessitate extending pile driving through December, and the pile driving is allowed by BOEM in accordance with the following procedures. The Lessee must notify BOEM in writing by September 1 that the Lessee believes that circumstances necessitate pile driving in December. The Lessee must submit to BOEM (at renewable_reporting@boem.gov) for written concurrence an enhanced survey plan for December 1 through December 31 to minimize the risk of exposure of NARWs to pile-driving noise, including noise from daily pre-construction geophysical surveys. BOEM will review the enhanced survey plan and provide comments, if any, on the plan within 30 calendar days of its submittal. The Lessee must resolve all comments on the enhanced survey plan to BOEM's satisfaction and receive BOEM's written concurrence before any pile driving occurs. However, the Lessee may conclusively presume BOEM's concurrence with the enhanced survey plan if BOEM provides no comments on the plan within 90 calendar days of its submittal. The Lessee must also follow the time-of-year enhanced mitigation measures specified in the applicable Biological Opinion. The Lessee must confirm adherence to time-of-year restrictions on pile driving in the pile-driving reports submitted with the FIR.	Marine Mammals, ESA-Listed Species	BOEM
BA-15	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Pile-Driving Weather, Time, and Visibility Restrictions	The Lessee must not conduct pile driving operations at any time when lighting or weather conditions (e.g., darkness, rain, fog, sea state) prevent visual monitoring of the full extent of the clearance and shutdown zones. In order to conduct nighttime pile driving, SouthCoast Wind would submit a Nighttime Pile Driving Plan (NPDP) as part of the Alternative Monitoring Plan (AMP) to BOEM and NMFS for approval. The NPDP will describe the methods, technologies, monitoring zones, and mitigation requirements for any nighttime pile driving activities. In the absence of an approved NPDP, all pile driving would be initiated during daytime and nighttime pile driving could only occur if unforeseen circumstances prevent the completion of pile driving during daylight hours and was deemed necessary to continue piling during the night to protect asset integrity or safety. The AMP, including the NPDP if nighttime pile driving is planned, must be submitted by the Lessee to BOEM and NMFS for review and approval 180 calendar days, but no later than 120 days, prior to the planned start of pile-driving. The full AMP may include deploying additional observers, alternative monitoring technologies such as night vision, thermal, and infrared technologies, and use of PAM and must demonstrate the ability and effectiveness to maintain clearance all pre-clearance and shutdown zones during daytime as outlined below in Part 1 and nighttime as outlined below in Part 2 to BOEM's and NMFS's satisfaction. The AMP must include two stand-alone components as described below: 1. Part 1 – Daytime when lighting or weather (e.g., fog, rain, sea state) conditions prevent visual monitoring of the full extent of the clearance and shutdown zones. Daytime being defined as one hour after civil sunrise to 1.5 hours before civil sunset. 2. Part 2 – Nighttime inclusive of weather conditions (e.g., fog, rain, sea state). Nighttime being defined as 1.5 hours before civil sunset to one hour after civil sunrise. The AMP should include, but is not limited to the following information: 1. Identification of night vision devices (e.g., mounted thermal/IR camera systems, hand-held or wearable NVDs, IR spotlights), if proposed for use to detect protected marine mammal and sea turtle species. 2. The AMP must demonstrate (through empirical evidence) the capability of the proposed monitoring methodology to detect marine mammals and sea turtles within the full extent of the established clearance and shutdown zones (i.e., species can be detected at the same distances and with similar confidence) with the same effectiveness as daytime visual monitoring (i.e., same detection probability). Only devices and methods demonstrated as being capable of detecting marine mammals and sea turtles to the maximum extent of the clearance and shutdown zones will be acceptable. 3. Evidence and discussion of the efficacy (range and accuracy) of each device proposed for low visibility monitoring must include an assessment of the results of field studies (e.g., Thayer Mahan demonstration), as well as supporting documentation regarding the efficacy of all proposed alternative monitoring methods (e.g., best scientific data available). 4. Procedures and timeframes for notifying NMFS and BOEM of SouthCoast Wind's intent to pursue nighttime pile driving. 5. Reporting procedures, contacts and timeframes. BOEM may request additional information, when appropriate, to assess the efficacy of the AMP.	Marine Mammals, ESA-Listed Species	BOEM
BA-16	Pre-C, C, O&M, D	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: PSO Requirements	. The Lessee must use PSOs provided by a third party. PSOs must have no Project- related tasks other than to observe, collect and report data, and communicate with and instruct relevant vessel crew regarding the presence of protected species and mitigation requirements (including brief alerts regarding maritime hazards). PSOs or any PAM operators serving as PSOs must have completed a commercial PSO training program for the Atlantic with an overall examination score of 80 percent or greater. The Lessee must provide training certificates for individual PSOs to BOEM upon request. And PSOs and PAM operators must be approved by NMFS before the start of a survey. Application requirements to become a NMFS-approved PSO for construction activities can be found online or for geological and geophysical surveys by sending an inquiry to nmfs.psoreview@noaa.gov. Specific PSO Requirements include:	Marine Mammals, Sea Turtles, ESA-Listed Species	BOEM, NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			1. At least one PSO must be on duty at all times as the lead PSO or as the PSO monitoring coordinator during pile driving. Total PSO coverage must be adequate to ensure effective monitoring to reliably detect whales and sea turtles in the identified clearance and shutdown zones and execute any pile driving delays or shutdown requirements. 2. At least one lead PSO must be present on each vessel. PSOs on transit vessels must be approved by NMFS but need not be authorized as a lead PSO. Lead PSOs must have prior approval from NMFS as an unconditionally approved PSO. 3. All PSOs on duty must be clearly listed and the lead PSO identified on daily data logs for each shift. 4. A sufficient number of PSOs, consistent with the Biological Opinion and as prescribed in the final Incidental Take Authorization (ITA), must be deployed to record data in real time and effectively monitor the required clearance, shutdown, or monitoring zone for the Project. 5. The duties of these PSOs include visual surveys in all directions around a pile; PAM; and continuous monitoring of sighted NARWs. 6. Where applicable, the number of PSOs deployed must meet the NARW enhanced seasonal monitoring requirements. A PSO must not be on watch for more than 4 consecutive hours and must be granted a break of no fewer than 2 hours after a 4-hour watch.		
BA-17	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Pile-Driving Monitoring Plan Requirements	The Lessee must submit a Pile-Driving Monitoring (PDM) Plan for review to BOEM (at renewable_reporting@boem.gov), BSEE (at OSWsubmittals@bsee.gov), and NMFS 180 calendar days, but no later than 120 days, before beginning the first pile-driving activities for the Project. DOI will review the PDM Plan and provide any comments on the plan within 90 calendar days of its submittal. The Lessee must resolve all comments on the PDM Plan to DOI's satisfaction before implementing the plan. If DOI provides no comments on the PDM Plan within 90 calendar days of its submittal, then the Lessee may conclusively presume DOI's concurrence with the plan. The PDM Plan must: 1. Contain information on the visual and PAM components of the monitoring describing all equipment, procedures, and protocols; 2. The PAM system must demonstrate a near-real-time capability of detection to the full extent of the 160 dB distance from the pile-driving location; 3. The PAM plan must include a detection confidence that a vocalization originated from within the clearance and shutdown zones to determine that a possible NARW has been detected. Any PAM detection of a NARW within the clearance/shutdown zone surrounding a pile must be treated the same as a visual observation and trigger any required delays in pile installation. 4. Ensure that the full extent of the harassment distances from piles are monitored for marine mammals and sea turtles to document all potential take; 5. Include number of PSOs or Native American monitors, or both, that will be used, the platforms or vessels upon which they will be deployed, and contact information for the PSO providers; 6. Include measures for enhanced monitoring capabilities in the event that poor visibility conditions unexpectedly arise, and pile driving cannot be stopped. Include an Alternative Monitoring Plan that provides for enhanced monitoring capabilities in the event that poor visibility conditions unexpectedly arise, and pile driving cannot be stopped. The Alternative Monitoring Plan must also include measures for deploying additional observers, using night vision goggles, or using PAM with the goal of ensuring the ability to maintain all clearance and shutdown zones in the event of unexpected poor visibility conditions. Describe a communication plan detailing the chain of command, mode of communication, and decision authority must be described. PSOs as determined by NMFS and BOEM must be used to monitor the area of the clearance and shutdown zones. Seasonal and species-specific clearance and shutdown zones must also be described in the PDM Plan including time-of-year requirements for NARWs. A copy of the approved PDM Plan must be in the possession of the lessee representative, the PSOs, impact-hammer operators, and any other relevant designees operating under the authority of the approved COP and carrying out the requirements on site.	Marine Mammals, Sea Turtles	BOEM, NMFS
BA-18	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Soft Start for Pile Driving	The Lessee must implement soft start techniques for all impact pile-driving, both at the beginning of a monopile installation and at any time following the cessation of impact pile-driving of 30 minutes or longer. The soft start procedure must include a minimum of 20 minutes of 4-6 strikes/minute at 10-20 percent of the maximum hammer energy.	ESA-Listed Species	BOEM
BA-19	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Pile-Driving Sound	The Lessee must ensure that the distance to the Level A harassment and Level B harassment thresholds, sea turtle injury and harassment thresholds, and Atlantic sturgeon injury and harassment thresholds are no larger than those modelled assuming 10 dB re 1 µPa noise attenuation is met by conducting field verification during pile-driving. The Lessee must submit a Sound Field Verification Plan (SFVP) for review and comment to the USACE, BOEM (at renewable_reporting@boem.gov), and NMFS (at nmfs.gar.incidental-take@noaa.gov) 180 calendar days, but no later than 120 days, before beginning the first pile-driving activities for the Project. DOI will review the SFVP and provide any comments on the plan within 30 calendar days of its submittal. The Lessee must resolve all comments on the SFVP to DOI's satisfaction before implementing the plan. The Lessee may conclusively presume DOI's concurrence with the SFVP if DOI	Sea Turtles, ESA-Listed Species	BOEM, NMFS, USACE

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		Field Verification Plan	provides no comments on the plan within 90 calendar days of its submittal. The Lessee must execute the SFVP and report the associated findings to BOEM for 3 monopile foundations, or as specified under the corresponding LOA for this action. The Lessee must conduct additional field measurements if it installs piles with a diameter greater than the initial piles, if it uses a greater hammer size or energy, or if it measures any additional foundations to support any request to decrease the distances specified for the clearance and shutdown zones. The Lessee must implement the SFVP requirements for verification of noise attenuation for at least 3 foundations for BOEM, in consultation with NMFS, to consider reducing zone distances. The Lessee must ensure that locations identified in the SFVP for each pile type are representative of other piles of that type to be installed and that the results are representative for predicting actual installation noise propagation for subsequent piles. The SFVP must describe how the effectiveness of the sound attenuation methodology will be evaluated. The SFVP must be sufficient to document impacts in Level B harassment zones for marine mammals and injury and behavioral disturbance zones for sea turtles and Atlantic sturgeon.		
BA-20	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Adaptive Refinement of Clearance Zones, Shutdown Zones, and Monitoring Protocols	The Lessee must reduce any unanticipated impacts on marine mammals and sea turtles by adjusting pile-driving monitoring protocols for clearance and shutdown zones, taking into account weekly monitoring results (see BA-28). Any proposed changes to monitoring protocols must be concurred with by DOI and NMFS before those protocols are implemented. Any reduction in the size of the clearance and shutdown zones for each foundation type must be based on at least 3 measurements submitted to BOEM and NMFS for review. For each 4,921 feet (1,500 meters) that a clearance or shutdown zone is increased based on the results from SFVP, the Lessee must deploy additional platforms and must deploy additional observers on those platforms. Should the shutdown zone for sei, fin, humpback, and sperm whales be decreased the full extent of the Level B harassment distance must be monitored using PAM and visual observations. Decreases in the distance of the clearance or shutdown zones for NARW and sea turtles are not permitted.	Marine Mammals, Sea Turtles	BOEM, NMFS
BA-21	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Pile-Driving Clearance Zones (No-go Zones) for Sea Turtles	The Lessee must minimize the exposure of ESA-listed sea turtles to noise that may result in injury or behavioral disturbance during pile-driving operations by tasking the PSOs to establish a clearance and shutdown zone for sea turtles during all pile-driving activities that is no less than 1,640 feet (500 meters) between 60 minutes before pile-driving activities, during pile driving and 30 minutes post-completion of pile-driving activity. Adherence to the 1,640-foot (500-meter) clearance and shutdown zones must be confirmed in the PSO reports	Sea Turtles	BOEM, NMFS
BA-22	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Impact Pile-Driving Clearance Zones (No-go Zones) for Marine Mammals	The Lessee must use visual monitoring by at least two PSOs and PAM during impact pile-driving activities following the standard protocols and data collection requirements. The Lessee must ensure that at least two PSOs are on duty on the impact pile driving platform and at least two PSO are on duty on a dedicated PSO vessel and establish the following clearance zones for NARWs to be used between 60 minutes before pile-driving activities and 30 minutes post-completion of pile-driving activity: • The Lessee must establish a clearance zone of 1.37 miles (2.2 kilometers) for large whales other than NARW using visual monitoring for impact pile driving. • The Lessee must also establish a PAM clearance zone of 3.1 miles (5 kilometers) and a PAM shutdown zone of 1.23 miles (2 kilometers) for NARWs. • Impact pile driving activity must be delayed when a NARW is visually observed by PSOs at any distance from the pile. Impact pile driving for all foundations must be delayed upon a confirmed PAM detection of a NARW, if the detection is confirmed to have been located within the 5 km clearance zone. • No pile driving may begin unless all clearance zones have been free of NARW for 30 minutes immediately before pile driving. The Lessee must deploy a real-time PAM system designed and verified to maintain a PAM clearance zone of 3.1 miles (5 km) and a shutdown zone of 1.23 miles (2 km) for all monopile foundations. • Real-time PAM must begin at least 60 minutes before pile driving to monitor a 3.1 mile (5 km) clearance zone. • The real-time PAM system must be configured to ensure that the PAM operator is able to review acoustic detections within approximately 15 minutes of the original detection in order to verify whether a NARW has been detected. • Impact pile driving must be suspended upon a confirmed PAM NARW vocalization within the PAM shutdown Zone detected and identified as a NARW. The detection will be treated as a NARW detection for mitigation purposes	Marine Mammals	BOEM
BA-23	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity:	The Lessee must use visual monitoring by at least two PSOs during vibratory pile-driving activities. The Lessee must ensure that PSOs are on a dedicated PSO vessel and establish clearance zones for NARWs to be used between 30 minutes before pile-driving activities and 30 minutes post-completion of pile-driving activity. For all ESA-listed Mysticete whales and sperm whales, a clearance zone of 4,921 feet (1,500 meters) is to be established. For sea turtles, a clearance zone of 1,640 feet (500 meters) is to be established.	Marine Mammals, ESA-Listed Species	BOEM

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		Vibratory Pile-Driving Clearance Zones (No-go Zones) for ESA-listed Species and Marine Mammals	Vibratory pile driving may begin only after PSOs have confirmed all clearance zones are clear of marine mammals. Vibratory pile driving must be suspended if a marine mammal is visually observed by PSOs within the shutdown zone. At all times of the year, any unidentified whale sighted by a PSO within 6,562 feet (2,000 meters) of the pile must be treated as if it were a NARW and trigger any required pre-construction delay or shutdowns during pile installation. Vibratory pile driving may begin only if all clearance zones are fully visible (e.g., not obscured by darkness, rain, fog, or snow) for at least 30 minutes as determined by the lead PSO. If conditions such as darkness, rain, fog, or snow prevent the visual detection of marine mammals in the clearance zones, construction activities must not begin until the full extent of all clearance zones are fully visible as determined by the lead PSO.		
BA-24	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Noise Mitigation for Impact Pile Driving	The Lessee must apply noise reduction technologies during all impact pile driving to minimize marine species noise exposure. The range measured to the Level B harassment threshold when noise mitigation devices are in use must be consistent with or less than the range modeled assuming 10 dB attenuation, determined via sound field verification of the modeled isopleth distances (e.g., Level B harassment distances). If a bubble curtain is used, the following requirements apply: Bubble curtains must distribute air bubbles around 100 percent of the piling perimeter for the full depth of the water column. The lowest bubble ring must be in contact with the seafloor for the full circumference of the ring, and the weights attached to the bottom ring must ensure 100 percent seafloor contact. No parts of the ring or other objects may prevent full seafloor contact of the lowest bubble ring. The Lessee must train personnel in the proper balancing of air flow to the bubblers. The Lessee must submit an inspection and performance report to DOI within 72 hours following the performance test. Any modifications to attenuation devices to meet the performance standards must occur before impact driving occurs and maintenance or modifications completed must be included in the report. The Lessee must ensure PSOs follow all pile driving reporting instructions and requirements.	ESA-Listed Species	BOEM and USACE
BA-25	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Pile-Driving Noise Reporting and Clearance or Shutdown Zone Adjustment	The Lessee must measure pile-driving noise in the field for at least three monopile foundations and submit initial results to NMFS, USACE, and BOEM (at renewable_reporting@boem.gov) as soon as they are available. BOEM will discuss the results as soon as feasible. The Lessee may request modification of the clearance and shutdown zones based on these results but must meet or exceed minimum distances for threatened and endangered species specified in the Biological Opinion (e.g., 3,280 feet [1,000 meters] for large whales and 1,640 feet [500 meters] for sea turtles). If the field measurements indicate that the isopleths for noise exposure are larger than those considered in the approved COP, the Lessee must coordinate with BOEM, BSEE, NMFS, and USACE to implement additional sound attenuation measures or larger clearance or shutdown zones before driving any additional piles. NMFS does not anticipate considering any reductions in the clearance or shutdown zones for NARWs.	ESA-Listed Species	BOEM, BSEE, NMFS, and USACE
BA-26	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Pile-Driving Work Within a Slow Zone	If a visually triggered NARW Slow Zone overlaps with the NARW Shutdown Zone, the PAM system detection must extend to the largest practicable detection zone. PSOs must treat any PAM detection of NARWs in the clearance and shutdown zones the same as a visual detection and call for the required delays or shutdowns in pile installation.	Marine Mammals	BOEM
BA-27	C	Wind Turbine Foundations Pile Driving/Impact Hammer Activity: Submittal of Raw Field Data Collected for Marine Mammals and Sea Turtles in the Pile-Driving Shutdown Zone	Within 24 hours of detection, the Lessee must report to BOEM (at renewable_reporting@boem.gov) and BSEE (at protectedspecies@bsee.gov) the sighting of any marine mammal or sea turtle in the shutdown zone that results in a shutdown or a power-down. In addition, PSOs must submit the raw data collected in the field and daily report forms including the date, time, species, pile identification number, GPS coordinates, time and distance of the animal when sighted, time the shutdown or power-down occurred, behavior of the animal, direction of travel, time the animal left the shutdown zone, time the pile driver was restarted or powered back up, and any photographs.	Marine Mammals, Sea Turtles, ESA-Listed Species	BOEM
BA-28	C	Wind Turbine Foundations Pile Driving/Impact	The Lessee must submit weekly PSO and PAM monitoring reports to DOI and NMFS during pile-driving. Weekly reports must document the daily start and stop times of all pile-driving, the daily start and stop times of associated observation periods by the PSOs, details on the deployment of PSOs, and all detections of marine mammals and sea turtles. The weekly reports must be submitted to BOEM (at renewable_reporting@boem.gov), BSEE (at OSWsubmittals@bsee.gov) and	ESA-Listed Species	BOEM, BSEE, NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
		Hammer Activity: Weekly and Final Pile-Driving Reports	NMFS Greater Atlantic Regional Fisheries Office, Protected Resources Division (at nmfs.gar.incidental- take@noaa.gov) every Wednesday during construction for the previous week (Sunday through Saturday) of monitoring of pile-driving activity. Weekly monitoring reports must include: Summaries of pile-driving activities and piles installed including, start and stop times, pile locations, and PSO coverage; Vessel operations (including port departures, number of vessels, type of vessel(s), and route); All protected species sightings; Vessel strike-avoidance measures taken; and any equipment shutdowns or takes that may have occurred. Weekly reports can consist of raw data. Required data and reports provided to DOI may be archived, analyzed, published, and disseminated by BOEM. PSO data must be reported weekly (Sunday through Saturday) from the start of visual and/or PAM efforts during pile-driving activities, and every week thereafter until the final reporting period upon conclusion of pile-driving activity. Any editing, review, and quality assurance checks must be completed only by the PSO provider prior to submission to NMFS and DOI. The Lessee must submit to DOI at renewable_reporting@boem.gov and OSWsubmittals@bsee.gov a final summary report of PSO monitoring 90 days following the completion of pile driving.		
BA-29	Pre-C, C, O&M, D	Marine Debris Awareness and Elimination: Marine Debris Awareness Training	The Lessee must ensure that vessel operators, employees, and contractors engaged in offshore activities pursuant to the approved COP complete marine trash and debris awareness training annually. The training consists of two parts: (1) viewing a marine trash and debris training video or slide show (described below); and (2) receiving an explanation from management personnel that emphasizes their commitment to the requirements. The marine trash and debris training videos, training slide packs, and other marine debris related educational material may be obtained at https://www.bsee.gov/debris or by contacting BSEE. The training videos, slides, and related material may be downloaded directly from the website. Operators engaged in marine survey activities must continue to develop and use a marine trash and debris awareness training and certification process that reasonably assures that their employees and contractors are in fact trained. a. The training process would include the following elements: b. Viewing of either a video or slide show by the personnel specified above; c. An explanation from management personnel that emphasizes their commitment to the requirements; d. Attendance measures (initial and annual); and e. Recordkeeping and the availability of records for inspection by DOI. By January 31 of each year, the Lessee would submit to DOI an annual report that describes its marine trash and debris awareness training process and certifies that the training process has been followed for the previous calendar year. The Lessee would send the reports via email to BOEM (at renewable_reporting@boem.gov) and to BSEE (at OSWsubmittals@bsee.gov).	ESA-Listed Species	BOEM, BSEE
BA-30	Pre-C, C, O&M, D	Marine Debris Awareness and Elimination: Marine Debris Reporting	The Lessee must report to DOI (using the email address listed on DOI's most recent incident reporting guidance) all lost or discarded marine trash and debris. This report must be made monthly and submitted no later than the fifth day of the following month. The Lessee is not required to submit a report for those months in which no marine trash and debris was lost or discarded. In addition, the Lessee must submit a report within 48 hours of the incident (48-hour Report) if the marine trash or debris could: (a) cause undue harm or damage to natural resources, including their physical, atmospheric, and biological components, with particular attention to marine trash or debris that could entangle or be ingested by marine protected species; or (b) significantly interfere with OCS uses (e.g., because the marine trash or debris is likely to snag or damage fishing equipment or presents a hazard to navigation). The information in the 48-hour report must be the same as that listed for the monthly report, but only for the incident that triggered the 48-hour Report. The Lessee must report to DOI via email to BOEM (at renewable_reporting@boem.gov) and BSEE (at OSWsubmittals@bsee.gov) if the object is recovered and, as applicable, describe any substantial variance from the activities described in the Recovery Plan that were required during the recovery efforts. The Lessee must include and address information on unrecovered marine trash and debris in the description of the site clearance activities provided in the decommissioning application required under 30 C.F.R. § 585.906. Materials, equipment, tools, containers, and other items used in OCS activities which are of such shape or properly secured to prevent loss overboard. All markings must clearly identify the owner and must be durable enough to resist the effects of the environmental conditions to which they may be exposed.	ESA-Listed Species	BOEM, BSEE
BA-31	O&M, D	Marine Debris: Periodic Underwater Surveys, Reporting of Monofilament and Other Fishing Gear Around WTG Foundations	The Lessee must monitor indirect impacts associated with charter and recreational fishing gear lost from expected increases in fishing around WTG foundations by surveying at least 10 different WTGs in the SouthCoast Wind Lease Area annually. Survey design and effort may be modified based upon previous survey results with review and concurrence by DOI. The Lessee must conduct surveys by remotely operated vehicles, divers, or other means to determine the frequency and locations of marine debris. The Lessee must report the results of the surveys to BOEM (at renewable_reporting@boem.gov) and BSEE (at OSWsubmittals@bsee.gov) in an annual report, submitted by April 30 for the preceding calendar year. Reports must be submitted in Word format. Photographic and videographic materials will be provided on a drive in a lossless format such as TIFF or Motion JPEG 2000. Reports must include daily survey reports that include the survey date, contact information of the operator, location, and pile identification number, photographic and/or video documentation of the survey and debris encountered, any animals sighted, and the disposition of any located debris (i.e., removed or left in place). Required data and reports may be archived, analyzed, published, and disseminated by BOEM. BMPs will be coordinated with NOAA's marine debris program.	ESA-Listed Species	BOEM, BSEE

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
BA-32	C	Establishment of Shutdown Zones for Vibratory Pile Driving	Ensure that vibratory pile-driving operations are carried out in a way that minimizes the exposure of listed sea turtles to noise that may result in injury or behavioral disturbance, PSOs will establish a 1,640-foot (500-meter) shutdown zone for all pile-driving activities. Adherence to the 1,640-foot (500-meter) shutdown zones must be reflected in the PSO reports. Any visual detection of sea turtles the 500-meter shutdown zones must trigger the required shutdown in pile installation. Upon a visual detection of a sea turtles entering or within the shutdown zone during pile-driving, SouthCoast Wind must shut down the pile-driving hammer (unless activities must proceed for human safety or for concerns of structural failure) from when the PSO observes, until: 1) The lead PSO verifies that the animal(s) voluntarily left and headed away from the clearance area; or 2) 30 minutes have elapsed without re-detection of the sea turtle(s) by the lead PSO Additionally, if shutdown is called for but SouthCoast Wind determines shutdown is not technically feasible due to human safety concerns or to maintain installation feasibility, reduced hammer energy must be implemented, when the lead engineer determines it is technically feasible to do so.	Sea Turtles	BOEM
BA-33	C, O&M, D	Sea turtle disentanglement	Vessels deploying fixed gear (e.g., pots/traps) must have adequate disentanglement equipment onboard, such as a (i.e., knife and boathook) onboard. Any disentanglement must occur consistent with the Northeast Atlantic Coast STDN Disentanglement Guidelines at https://www.reginfo.gov/public/do/DownloadDocument?objectID=102486501 and the procedures described in "Careful Release Protocols for Sea Turtle Release with Minimal Injury" (NOAA Technical Memorandum 580; https://repository.library.noaa.gov/view/noaa/3773).	Sea Turtles, ESA-Listed Species	BOEM, BSEE, NMFS
BA-34	C, O&M, D	Sea turtle/Atlantic sturgeon identification and data collection	Any sea turtles or Atlantic sturgeon caught or retrieved in any fisheries survey gear must first be identified to species or species group. Each ESA-listed species caught or retrieved must then be documented using appropriate equipment and data collection forms. Biological data collection, sample collection, and tagging activities must be conducted as outlined below. Live, uninjured animals must be returned to the water as quickly as possible after completing the required handling and documentation. a. The Sturgeon and Sea Turtle Take Standard Operating Procedures must be followed (https://media.fisheries.noaa.gov/2021-11/Sturgeon%20%26%20Sea%20Turtle%20Take%20SOPs_external_11032021.pdf). b. Survey vessels must have a passive integrated transponder (PIT) tag reader onboard capable of reading 134.2 kHz and 125 kHz encrypted tags (e.g., Biomark GPR Plus Handheld PIT Tag Reader). This reader must be used to scan any captured sea turtles and sturgeon for tags, and any tags found must be recorded on the take reporting form (see below). c. Genetic samples must be taken from all captured Atlantic sturgeon (alive or dead) to allow for identification of the DPS of origin of captured individuals and tracking of the amount of incidental take. This must be done in accordance with the Procedures for Obtaining Sturgeon Fin Clips (https://media.fisheries.noaa.gov/dam-migration/sturgeon_genetics_sampling_revised_june_2019.pdf). i. Fin clips must be sent to a NMFS-approved laboratory capable of performing genetic analysis and assignment to DPS of origin. SouthCoast Wind must cover all reasonable costs of the genetic analysis. Arrangements for shipping and analysis must be made before samples are submitted and confirmed in writing to NMFS within 60 days of the receipt of the Project BiOp with ITS. Results of genetic analyses, including assigned DPS of origin must be submitted to NMFS within 6 months of the sample collection. ii. Subsamples of all fin clips and accompanying metadata forms must be held and submitted to a tissue repository (e.g., the Atlantic Coast Sturgeon Tissue Research Repository) on a quarterly basis. The Sturgeon Genetic Sample Submission Form is available for download at: https://media.fisheries.noaa.gov/2021-02/Sturgeon%20Genetic%20Sample%20Submission%20sheet%20for%20S7_v1.1_Form%20to%20Use.xlsx?nullhttps://www.fisheries.noaa.gov/new-england-mid-atlantic/consultations/section-7-take-reporting-programmatics-greater-atlantic. d. All captured sea turtles and Atlantic sturgeon must be documented with required measurements and photographs. The animal's condition and any marks or injuries must be described. This information must be entered as part of the record for each incidental take. Particularly, a NMFS Take Report Form must be filled out for each individual sturgeon and sea turtle (download at: https://media.fisheries.noaa.gov/2021-07/Take%20Report%20Form%2007162021.pdf?null) and submitted to NMFS as described in the take notification measure below.	Sea Turtles, ESA-Listed Species	BOEM, BSEE, NMFS
BA-35	C, O&M, D	Sea turtle/Atlantic sturgeon handling and resuscitation guidelines	Any sea turtles or Atlantic sturgeon caught and retrieved in gear used in fisheries surveys must be handled and resuscitated (if unresponsive) according to established protocols provided at-sea conditions are safe for those handling and resuscitating the animal(s) to do so. Specifically: a. Priority must be given to the handling and resuscitation of any sea turtles or sturgeon that are captured in the gear being used. Handling times for these species must be minimized, and if possible, kept to 15 minutes or less to limit the amount of stress placed on the animals. b. All survey vessels must have onboard copies of the sea turtle handling and resuscitation requirements (found at 50 CFR 223.206(d)(1)) before begging any on-water activity (download at: https://media.fisheries.noaa.gov/dam-migration/sea_turtle_handling_and_resuscitation_measures.pdf). These handling and resuscitation procedures must be carried out any time a sea turtle is incidentally captured and brought onboard the vessel during survey activities. c. If any sea turtles that appear injured, sick, or distressed, are caught and retrieved in fisheries survey gear, survey staff must immediately contact the Greater Atlantic Region Marine Animal Hotline at 866-755-6622 for further instructions and guidance on handling the animal, and potential coordination of transfer to a	Sea Turtles, ESA-Listed Species	BOEM, BSEE, NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			rehabilitation facility. If survey staff are unable to contact the hotline (e.g., due to distance from shore or lack of ability to communicate via phone), the USCG must be contacted via VHF marine radio on Channel 16. If required, hard-shelled sea turtles (i.e., non-leatherbacks) may be held on board for up to 24 hours and managed in accordance with handling instructions provided by the Hotline before transfer to a rehabilitation facility. d. Survey staff must attempt resuscitate any Atlantic sturgeon that are unresponsive or comatose by providing a running source of water over the gills as described in the Sturgeon Resuscitation Guidelines (https://media.fisheries.noaa.gov/dam-migration/sturgeon_resuscitation_card_06122020_508.pdf). e. If appropriate cold storage facilities are available on the survey vessel, any dead sea turtle or Atlantic sturgeon must be retained on board the survey vessel for transfer to an appropriately permitted partner or facility on shore unless NMFS indicates that storage is unnecessary, or storage is not safe. f. Any live sea turtles or Atlantic sturgeon caught and retrieved in gear used in any fisheries survey must ultimately be released according to established protocols including safety considerations.		
BA-36	C, O&M, D	Lost Survey Gear	If any survey gear is lost, all reasonable efforts that do not compromise human safety would be undertaken to recover the gear. All lost gear would be reported to NMFS (nmfs.gar.incidental-take@noaa.gov) and BSEE (OSWsubmittals@bsee.gov) within 24 hours of the documented time of missing or lost gear. This report would include information on any markings on the gear and any efforts undertaken or planned to recover the gear	ESA-Listed Species	NMFS, BSEE
Conservation Measures and Reasonable and Prudent Measures and Terms and Conditions from the USFWS Biological Opinion Issued September 1, 2023					
Conservation Measures					
1	Project design, O&M	Turbine configuration and maintenance	a. The WTG design provides a wind turbine air gap (minimum blade tip elevation to the sea surface) to minimize collision risk to marine birds (e.g., roseate terns) that may fly close to the ocean surface. b. To minimize attracting birds to operating turbines, SouthCoast Wind must install bird perching-deterrent devices where such devices can be safely deployed on WTGs and ESPs. The location of bird-deterrent devices proposed by SouthCoast Wind must be based on best management practices applicable to the appropriate operation and safe installation of the devices. SouthCoast Wind must submit for BOEM and Service approval a plan to deter perching on offshore infrastructure by listed species. The plan must include the type(s) and locations of bird perching-deterrent devices, include a maintenance plan for the life of the project, allow for modifications and updates as new information and technology become available, and track the efficacy of the deterrents. The plan will be based on best available science regarding the effectiveness of perching deterrent devices on minimizing collision risk.	Birds	BOEM, BSEE, and USFWS
2	O&M	Offshore Lighting	To aid safe navigation, SouthCoast Wind must comply with all Federal Aviation Administration (FAA), USCG, and BOEM lighting, marking, and signage requirements. a. SouthCoast Wind will use lighting technology that minimizes impacts on avian species to the extent practicable. b. SouthCoast Wind will implement an ADLS on WTGs and ESPs. SouthCoast Wind must use an FAA-approved vendor for the ADLS, which will activate the FAA hazard lighting only when an aircraft is in the vicinity of the wind facility to reduce visual impacts at night. SouthCoast Wind must confirm the use of an FAA-approved vendor for ADLS on WTGs and ESPs in the Fabrication and Installation Report. c. SouthCoast Wind is required to light each WTG and ESP in a manner that is visible by mariners in a 360-degree arc around the structure. Conditional on USCG approval, and to minimize the potential of attracting migratory birds, the top of each USCG-required marine navigation light will be shielded to minimize upward illumination. Coordination with the USCG regarding maritime navigation lighting occurs post-COP approval, generally at least 120 calendar days prior to installation. The Service will be afforded an opportunity to review a copy of SouthCoast Wind's application to USCG to establish Private Aids to Navigation (PATON), which includes a lighting, marking, and signaling plan. The PATON application will include design specifications for maritime navigation planning. Following approval of the PATON by the USCG, the BOEM and the Service will work together to evaluate the USCG-approved navigation lighting system, in order to characterize the color, intensity, and duration of any light from maritime lanterns that is likely to reach the typical flight heights of listed birds and will assess the degree to which the light is likely to attract or disorient listed birds. This information will be considered, as appropriate, in future estimates of projected collision levels, in any future updates to the ITS accompanying this BO, and in future iterations of the Compensatory Mitigation Plan, if any.	Birds, Bats	BOEM, BSEE, and USFWS
3	O&M	Collision Risk Model Support	The BOEM has funded the development of SCRAM, which builds on and improves earlier collision risk modeling frameworks. The Service fully supports SCRAM as a scientifically sound method for integrating best available information to assess collision risk for the listed bird species. The first generation of SCRAM was released in early 2023 and still reflects a number of consequential data gaps and uncertainties. The BOEM has already committed to funding Phase 2 of the development of SCRAM. We expect that the current limitations of SCRAM will decrease substantially over time as more tracking data are incorporated into the model (e.g., from more individual birds tagged in more geographic areas, improved bird tracking capabilities, and emerging tracking technologies), and as modeling methods and computing power continue to improve. Via this Conservation Measure, the BOEM commits to continue funding the refinement and advancement of SCRAM, or its	Birds	BOEM, BSEE, and USFWS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			successor, with the goal of continually improving the accuracy and robustness of collision mortality estimates. This commitment is subject to the allocation of sufficient funds to the BOEM from Congress. This commitment will remain in effect until one of the following occurs: iii. the SouthCoast Wind turbines cease operation; iv. the Service concurs that a robust weight of evidence has demonstrated that collision risks to all listed birds from SouthCoast Wind turbine operation are negligible (i.e., the risk of take from WTG operation is found to be discountable); or v. the Service concurs that further development of SCRAM (or its successor) is unlikely to improve the accuracy or robustness of collision mortality estimates.		
4	O&M	Collision Risk Model Utilization	The BOEM will work cooperatively with the Service to re-run the SCRAM model (or its successor) for the SouthCoast Wind project according to the following schedule: • At least annually for the first 3 years of WTG operation. • At least every other year for years 4 to 10 of WTG operation (i.e., years 4, 6, 8, and 10). • At least every 5 years between year 10 and the termination of WTG operation (i.e., years 15, 20, 25, and 30). Between these regularly scheduled model runs, the BOEM will also re-run the SCRAM model (or its successor) within 90 days of each major model release or update, and at any time upon request by the Service or SouthCoast Wind, and at any time as desired by the BOEM. Prior to each model run, the BOEM and the Service will reach agreement on model inputs based on best available science, and the agencies may opt for multiple model runs using a range of inputs to reflect uncertainties in the inputs." The above schedule may be altered upon the mutual agreement of the BOEM and the Service. The schedule is subject to sufficient allocation of funds to the BOEM from Congress. This commitment will remain in effect until one of the following occurs: i. the SouthCoast Wind turbines cease operation; ii. the Service concurs that a robust weight of evidence has demonstrated that collision risks to all listed birds from SouthCoast Wind turbine operation are negligible (i.e., the risk of take from WTG operation is found to be discountable); or iii. the Service concurs that further model runs are unlikely to improve the accuracy or robustness of collision mortality estimates.	Birds	BOEM, BSEE, and USFWS
5	C, O&M, D	Monitoring and Data Collection	An avian species monitoring plan for ESA-listed species and/or other priority species or groups will be developed and coordinated appropriate state wildlife agencies and the Service and implemented as required. The BOEM will require SouthCoast Wind to develop and implement an Avian and Bat Post- Construction Monitoring Plan (ABPCMP) based on the ABPCMF (SouthCoast BA, Appendix C) in coordination with the BSEE, the Service, appropriate state wildlife agencies, and other relevant regulatory agencies. Annual monitoring reports will be used to determine the need for adjustments to monitoring approaches, consideration of new monitoring technologies, and/or additional periods of monitoring. Prior to or concurrent with offshore construction activities, SouthCoast Wind must submit an ABPCMP for BOEM, the BSEE and Service review. The BOEM, the BSEE and the Service will review the ABPCMP and provide any comments on the plan within 30 calendar days of its submittal. SouthCoast Wind must resolve all comments on the ABPCMP to the satisfaction of the BOEM, the BSEE and the Service before implementing the plan and prior to the start of WTG operations. The objectives of the monitoring plan will include: (1) to advance understanding of how the target species utilize the offshore airspace and do (or do not) interact with the wind farm; (2) to improve the collision estimates from SCRAM (or its successor) for the three listed bird species; and (3) to inform any efforts aimed at minimizing collisions (see Conservation Measures 1 and 2, above) or other project effects on target species. a. Monitoring. SouthCoast Wind must develop an ABPCMP The ABPCMP will allow for changing methods over time (see Conservation Measure 5.d, below) in order to regularly update and refine collision estimates for listed birds. The plan will include an initial monitoring phase involving deployment of Motus radio tags on listed birds, in conjunction with installation and operation of Motus Wildlife Tracking System (Motus) receiving stations on turbines in the Lease Area, following offshore Motus recommendations. The initial phase may also include deployment of satellite-based tracking technologies (e.g., Global Positioning System [GPS] or Argos tags). b. Annual Monitoring Reports. SouthCoast Wind must submit to the BOEM (at renewable_reporting@boem.gov), the BSEE (via TIMSWeb and at protectedspecies@bsee.gov), and the Service, a comprehensive report after each full year of monitoring (pre- and post-construction) within 12 months of completion of the last avian survey. The report must include all data, analyses, and summaries regarding ESA-listed and non-ESA-listed birds and bats. The BOEM, the BSEE, and the Service will use the annual monitoring reports to assess the need for reasonable revisions (based on subject matter expert analysis) to the ABPCMP. The BOEM, the BSEE, and the Service reserve the right to require reasonable revisions to the ABPCMP and may require new technologies as they become available for use in offshore environments.	Birds, Bats	BOEM, BSEE, and USFWS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			c. Post-Construction Quarterly Progress Reports. SouthCoast Wind must submit quarterly progress reports during the implementation of the ABPCMP to the BOEM (at renewable_reporting@boem.gov), the BSEE, and the Service by the 15th day of the month following the end of each quarter during the first full year that the Project is operational. The progress reports must include a summary of all work performed, an explanation of overall progress, and any technical problems encountered. d. Monitoring Plan Revisions. Within 30 calendar days of submitting the annual monitoring report (pursuant to Conservation Measure 5.b, above), SouthCoast Wind must meet with the BOEM, the BSEE, the Service, and appropriate state wildlife agencies to discuss the following: the monitoring results; the potential need for revisions to the ABPCMP, including technical refinements or additional monitoring; and the potential need for any additional efforts to reduce impacts. If, based on this annual review meeting, the BOEM and the Service jointly determine that revisions to the ABPCMP are necessary, the BOEM will require SouthCoast Wind to modify the ABPCMP. If the projected collision levels, as informed by monitoring results, deviate substantially from the effects analysis included in this BO, SouthCoast Wind must transmit to the BOEM recommendations for new mitigation measures and/or monitoring methods. The frequency, duration, and methods for various monitoring efforts in future revisions of the ABPCMP will be determined adaptively based on current technology and the evolving weight of evidence regarding the likely levels of collision mortality for each listed bird species. The effectiveness and cost of various technologies/methods will be key considerations when revising the plan. Grounds for revising the ABPCMP include, but are not limited to: i. greater than expected levels of collision of listed birds; ii. evolving data input needs (as determined by the BOEM and the Service) for SCRAM (or its successor); iii. changing technologies for tracking or otherwise monitoring listed birds in the offshore environment that are relevant to assessing collision risk; iv. new information or understanding of how listed birds utilize the offshore environment and/or interact with wind farms; and v. a need (as determined by the BOEM and the Service) for enhanced coordination and alignment of tracking, monitoring, and other data collection efforts for listed birds across multiple wind farms/leases on the OCS. The BOEM will require SouthCoast Wind to continue implementation of appropriate monitoring activities for listed birds (under the current and future versions of the ABPCMP) until: i. the SouthCoast Wind turbines cease operation; . the Service concurs that a robust weight of evidence has demonstrated that collision risks to all three listed birds from SouthCoast Wind turbine operation are negligible (i.e., the risk of take from WTG operation is found to be discountable); or i. the Service concurs that further data collection is unlikely to improve the accuracy or robustness of collision mortality estimates and is unlikely to improve the ability of the BOEM and SouthCoast Wind to reduce or offset collision mortality. e. Operational Reporting (Operations). SouthCoast Wind must submit to the BOEM (at renewable_reporting@boem.gov) and the BSEE (via TIMSWeb and at protectedspecies@bsee.gov) an annual report summarizing monthly operational data calculated from 10-minute supervisory control and data acquisition (SCADA) data for all turbines together in tabular format: the proportion of time the turbines were actually spinning each month, the average rotor speed (monthly revolutions per minute) of spinning turbines plus 1 standard deviation, and the average pitch angle of blades (degrees relative to rotor plane) plus 1 standard deviation. The BOEM and the BSEE will use this information as inputs for avian collision risk models to assess whether the results deviate substantially from the effects analysis included in this Opinion. f. Raw Data. SouthCoast Wind must store the raw data from all avian and bat surveys and monitoring activities according to accepted archiving practices. Such data must remain accessible to the BOEM, the BSEE, and the Service, upon request for the duration of the lease. SouthCoast Wind must work with the BOEM to ensure the data are publicly available. All avian tracking data (i.e., from radio and satellite transmitters) will be stored, managed, and made available to the BOEM, the BSEE and the Service following the protocols and procedures outlined in the agency document entitled Guidance for Coordination of Data from Avian Tracking Studies, or its successor.		
6	C, O&M, D	Incidental Mortality and Reporting	SouthCoast Wind must provide an annual report to the BOEM, the BSEE, and the Service documenting any dead (or injured) birds or bats found on vessels and structures or in the ocean during construction, operations, and decommissioning. The report must contain the following information: the name of species (if possible), date found, location, a picture to confirm species identity (if possible), and any other relevant information. Carcasses with Federal or research bands must be reported to the United States Geological Survey's (USGS) Bird Banding Laboratory. Any occurrence of a dead ESA-listed bird or bat must be reported to the BOEM, the BSEE, and the Service as soon as practicable (taking into account crew and vessel safety), ideally within 24 hours and no more than two business days after the sighting. If practicable, the dead specimen will be carefully collected and preserved in the best possible state, contingent on the acquisition of any necessary wildlife permits and compliance with SouthCoast Wind health and safety standards. Species-specific Conservation Measures	Birds, Bats	BOEM, BSEE, and USFWS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			Northern long-eared bat and tri-colored bat • The northern long-eared bat is listed as a species of greatest conservation need in the 2015 Rhode Island Wildlife Action Plan. Northern long-eared bats use maternity roost sites during the summer and hibernacula sites during the winter, and the loss of these habitat features is a threat to northern long-eared bats. On April 8, 2022, SouthCoast Wind contacted RIDEM Division of Fish and Wildlife, for information on northern long- eared bat maternity roosts and hibernacula in the vicinity of the Project. According to her response, dated April 12, 2022, there are no known northern long-eared bat maternity roosts or hibernacula in or near (within 5 miles) the Project area. Conversion of foraging and roosting habitats is also expected to be minimal for the Project as the onshore Project components are planned to be installed primarily within roadways and roadway shoulders to mitigate impacts on rare species and tree clearing will be avoided. • Tree Clearing Time-of-Year Restrictions during construction. The Lessee (SouthCoast Wind) must not clear trees greater than 3 inches (7.6 centimeters) in diameter at breast height from June 1 to July 31 of any year to protect northern long-eared bats. The Lessee may choose to conduct presence/probable absence surveys pursuant to current USFWS protocols for purposes of requesting and obtaining a waiver from this time-of-year restriction on tree clearing. The Lessee must submit any requests for waivers from this time-of-year restriction to the Department of the Interior (DOI) and such requests must be approved in writing by DOI. • SouthCoast Wind will site Project components to avoid locating onshore facilities or landfall sites in or near significant fish and wildlife habitats, including known hibernacula, maternal roosting colonies or other concentration areas as practicable. The proposed onshore substation site and converter station will be constructed in primarily open, developed areas. • SouthCoast Wind will site Project components to avoid locating onshore facilities or landfall sites in or near significant fish and wildlife habitats, including known hibernacula, maternal roosting colonies or other concentration areas as practicable. The proposed onshore substation site and converter station will be constructed in primarily open, developed areas. • SouthCoast Wind will implement a Vegetation Management Plan as approved by National Heritage and Endangered Species Program (NHESP), RIDEM, and the Massachusetts Department of Agricultural Resources. • SouthCoast Wind will consult with BOEM and USFWS to discuss best management practices (BMPs) available to avoid and minimize potential effects from construction/decommissioning on bats. • SouthCoast Wind is requiring construction equipment to be operated such that the construction-related noise levels comply with applicable sections of the MassDEP Air Quality Regulation at 310 CMR 7.10, which would minimize impacts on bats. Sandplain gerardia • Incorporate use of horizontal directional drilling (HDD) at landfall locations to avoid disturbance to shorelines and coastal habitats to the extent practicable.		
Reasonable and Prudent Measures and Terms and Conditions					
1	Pre- O&M and O&M	Collision Minimization Report	Periodically review current technologies and methods for minimizing collision risk of migratory birds with WTGs, including but not limited to: WTG coloration/marking, lighting, avian deterrents, remote sensing such as radar and thermal cameras, and limited WTG operational changes.	Birds	BOEM, BSEE, and USFWS
2	Pre- O&M and O&M	Collision Detection Report	Periodically review current technologies and methods for minimizing collision risk of listed birds. a. Prior to the start of WTG operations at SouthCoast Wind, the BOEM must compile, from existing project documentation (e.g., the BA, other consultation documents, the final EIS, the COP), a stand-alone summary of technologies and methods that the BOEM evaluated to reduce or minimize bird collisions at the SouthCoast Wind WTGs. b. Within 5 years of the start of WTG operation, and then every 5 years for the life of the project, the BOEM must prepare a Collision Minimization Report (CMR), reviewing best available scientific and commercial data on technologies and methods that have been implemented, or are being studied, to reduce or minimize bird collisions at offshore and onshore WTGs. The review must be global in scope. c. The BOEM must distribute a draft CMR to the Service, SouthCoast Wind, and appropriate state agencies for a 60-day review period. The BOEM must address all comments received during the review period and issue the final report within 60 days of the close of the review period. d. Following issuance of the final CMR, the Service may call for a meeting. Within 60 days following a call for such a meeting, the BOEM must convene a meeting with the Service, SouthCoast Wind, and appropriate state agencies to discuss the CMR and seek consensus on whether implementation of any technologies/methods is warranted.	Birds	BOEM, BSEE, and USFWS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
NMFS EFH Conservation Recommendations issued September 23, 2024[1]					
EFH CR 1	Pre-C, C	Turbine installation	To minimize risk of adverse effects on Nantucket Shoals and associated tidal mixing fronts that overlap the lease area, development should first occur in the southern portion of the Lease Area (Project 2). Additional research and monitoring of operational effects on the Nantucket Shoals tidal front should be implemented to inform mitigation options prior to development in the northern portion of the Lease Area (Project 1).	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 2	C	Turbine removal	Should BOEM deem EFH CR #1 as infeasible for adoption, we recommend the maximum number of turbines feasible be removed at the northeastern end of the Lease Area to reduce the extent of impacts on EFH adjacent to Nantucket Shoals and overlap with Atlantic cod spawning areas.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 3	C	Oceanographic features monitoring program	Development and implementation of a monitoring program to evaluate changes to oceanographic features from project operations and understand impacts of those changes on the persistent tidal mixing front of Nantucket Shoals and associated EFH for managed species should be required. Development of the monitoring plan should be conducted in coordination with GARFO and NEFSC. Based on the results of this monitoring program, additional mitigation measures should be identified and implemented.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 4	C	Pile driving timing restriction	To minimize adverse effects on Atlantic cod spawning aggregations within and adjacent to the project area, and to reduce the risk of population-level effects on this species, no pile driving should occur in the Lease Area between November 1 and March 31 of each year.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 5	C	Bottom-disturbing construction activity timing restriction	In-water bottom-disturbing construction activities in the Lease Area or the Brayton Point export cable corridor (ECC) that overlap the Southern New England Habitat Area of Particular Concern (HAPC) should not be permitted to occur inshore of the 50-meter isobath between November 1 and March 31 of each year.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 6	C	UXO timing restriction	To the extent practicable, detonation of UXO/MEC, should not be conducted in the lease area or the Brayton Point ECC that overlaps the Southern New England HAPC from November 1 through March 31 of each year.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 7	C	HRG survey timing restriction	High-resolution geophysical (HRG) sub-bottom profiling (e.g., sparkers, boomers) survey activities should not be permitted to occur inshore of the 50-meter isobath within the Southern New England HAPC from November 1 through March 31 of each year.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 8	Pre-C, C, O&M, D	Passive acoustic and telemetry studies	Develop and implement passive acoustic and telemetry surveys within the Lease Area and the Brayton Point ECC to evaluate Atlantic cod spawning activity in the project area. This should be conducted prior to, during, and post construction to identify the full scope of the area affected by project construction and operation and to assess individual, synergistic, and cumulative effects of the Project on cod spawning activity. a) Specifically, provide continuous monitoring of Atlantic cod spawning aggregations within, and immediately adjacent to, the Lease Area between November 1 and March 31 prior to the construction of the project, during project construction, and a minimum of 5 years post construction. b) Increase coverage of passive acoustic receivers within the Southern New England HAPC and analyze for Atlantic cod spawning activity. c) Add an additional glider and increased tagging of Atlantic cod to the ongoing survey to increase the spatial coverage and extend coverage in the SouthCoast Wind Project area and adjacent areas. The ongoing survey should focus on adding survey coverage (i.e., increase the number of glider tracts) within the Project area to provide detection of cod spawning activity within the project area before, during, and after construction. d) The survey coverage should extend outside the Lease Area within areas where project effects occur (e.g., wind wake effects) to assess individual, synergistic, and cumulative effects of the project construction and operation on the distribution of cod spawning activity.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS

[1] NMFS issued conservation recommendations to BOEM, BSEE, USACE, and EPA for the SouthCoast Wind project via letter dated September 23, 2024. As required by section 305(b)(4)(B) of the Magnuson-Stevens Act, BOEM and co-action agencies will provide a detailed response to these conservation recommendations to NMFS regarding which measures will be adopted, partially adopted, or not adopted. At the time of FEIS issuance, BOEM and co-action agencies have not made final determinations regarding which conservation recommendations each agency intends to adopt or partially adopt. As such, the full list of conservation recommendations received from NMFS is included in this document.

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			e) Data and results from this study should be made available to NOAA Fisheries Habitat and Ecosystem Services Division (HESD) at NMFS.GAR.HESDoffshorewind@noaa.gov.		
EFH CR 9		Converter station relocation	Relocate the converter station (and associated cooling water intake system [CWIS]) offshore of the overlapping benthic ridge feature (located at the 45-meter isobath) to locations closer to 50 meters or greater depths to minimize impacts on existing biogenic habitat, EFH from entertainment of eggs and larvae that are concentrated in this area as a result of the Nantucket Shoals tidal front, and to reduce impacts on Atlantic cod spawning activity.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 10	C	Converter station technology	The converter station CWIS should be retrofitted with a closed-cycle cooling system when the technology is made commercially viable. If a closed-loop system is deemed infeasible at the time of construction, the feasibility of upgrading the proposed CWIS with a closed-cycle cooling system and/or incorporating best available technologies should be evaluated every 5 years upon re-application of the National Pollutant Discharge Elimination System (NPDES) permit for operation of the converter station. This should be included as a condition of Construction and Operation Plan (COP) approval and the NPDES permit.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 11	C	Converter station	The converter station CWIS should be required to use one dedicated intake pump or dual pump operation at reduced capacity equipped with a variable frequency drive (VFD) to minimize water withdrawals and reduce the extent of entrainment of eggs and larvae.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 12	C, O&M, D	Ichthyoplankton and Zooplankton monitoring	Ichthyoplankton and zooplankton monitoring at the converter station (and associated CWIS) should be required for the life of the project. All data and results from the ichthyoplankton and thermal monitoring should be made available to NMFS HESD at NMFS.GAR.HESDoffshorewind@noaa.gov.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 13	Pre-C	Ichthyoplankton and Zooplankton monitoring plan	An ichthyoplankton and zooplankton monitoring plan should be provided to NMFS HESD at NMFS.GAR.HESDoffshorewind@noaa.gov for review and comment prior to finalizing requirements of the NPDES permit to determine if increased sampling frequency and/or additional recommendations are necessary.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 14	Pre-C, C	Seabed preparation	Seabed preparation and associated IAC cable installation should not be permitted to occur in the Lease Area where comprehensive, high-resolution geotechnical and geophysical surveys and benthic habitat mapping have not been conducted and their results analyzed.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 15	Pre-C, C	Acoustic survey data	Collection of acoustic data (bathymetry, multi-beam backscatter, side-scan sonar) and ground truthing of the habitats that occur in the Lease Area through comprehensive, high-resolution benthic surveys with seafloor sampling for CR#14 should be required prior to construction. Survey data should be provided to NMFS HESD at NMFS.GAR.HESDoffshorewind@noaa.gov to determine if additional conservation recommendations (CRs) are needed, including recommendations for micrositing IACs to minimize impacts on sensitive habitats.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 16	C	Benthic habitat avoidance	Site the Brayton Point ECC (between KP Segments 55–58) along the northeastern edge of the cable corridor to avoid and minimize sensitive benthic habitats associated with Brown's Ledge. KP Segment numbers are based on labels identified in the benthic data viewer. Compensatory mitigation should be provided for unavoidable impacts.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 17	C	Microsite WTGs	Microsite WTGs off of benthic ridge features with associated biogenic habitats formed by the active tidal front areas. Benthic ridge features are delineated based on the high-resolution multibeam backscatter, side scan sonar, and sediment profile and plan view imaging (SPI/PV) data provided in the benthic data viewer. Specifically, the following WTGs should be microsited: a) BK39 should be shifted the maximum allowable distance west. b) BL38 should be shifted the maximum allowable distance west. c) BL39 should be sifted the maximum allowable distance west. d) BL42 should be shifted the maximum allowable distance east. e) BL43 should be sited outside of the active tidal front and associated benthic ridge feature. f) BM40 should be shifted the maximum allowable distance east. g) BM41 should be shifted the maximum allowable distance east.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
EFH CR 18	C	Dredge material placement	Dredge material should not be placed within sensitive benthic habitats for any required dredging along the Brayton Point ECC. Habitat maps (based on high-resolution multibeam backscatter, side scan sonar, and boulders) delineating sensitive benthic habitat areas should be provided to vessel operators to facilitate avoidance of these areas.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 19	C	Boulder relocation	To minimize impacts on sensitive benthic habitats from boulder/cobble removal/relocation activities, boulders and cobbles should (i) be relocated in areas immediately adjacent to existing similar complex bottom; (ii) placed in a manner that does not hinder navigation or impede commercial fishing; and (iii) avoid impacts on existing complex habitats. To minimize impacts on sensitive benthic habitats from boulder/cobble removal/relocation activities, boulders that will be relocated using boulder "pick" methods should be relocated outside the area necessary to clear and placed along the edge of existing complex habitats such that the placement of the relocated boulders will result in a marginal expansion of complex habitats into soft-bottom habitats.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 20	C	Boulder relocation	A boulder plow should not be permitted to be used for boulder relocation in the project area due to the limited control the plow has on avoiding adverse impacts on existing sensitive habitats and fishing operations.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 21	Pre-C	Boulder study results	Results from SouthCoast Wind's boulder study, which is planned to be completed in the third and/or fourth quarter of 2024 should be provided to NMFS HESD at NMFS.GAR.HESDoffshorewind@noaa.gov prior to construction to determine if additional CRs are needed. The report should include information on how EFH CR #17 and EFH #18 will be implemented into boulder relocation activities.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 22	Pre-C, C, O&M, D	Seafloor surveying and monitoring	In all project areas where seafloor preparation activities include the use of plows, jets, grapnel runs or similar methods, post-construction acoustic surveys capable of detecting bathymetry changes of 0.5 meter or less, should be completed to demonstrate how the bottom was modified by preparation and construction activities. Post-construction acoustic survey data should be provided to NMFS HESD in a viewable format at NMFS.GAR.HESDoffshorewind@noaa.gov.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 23			Berms exceeding three feet (from existing grade) that are created through the use of plows, jets, or other similar methods should be restored to pre-construction conditions.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 24	C	Anchoring	Avoid anchoring or placing jack-up barge spud cans or footings on/in sensitive benthic habitats including any area where large boulders (>/= 0.5 meter in diameter) or medium to high multibeam backscatter returns occur. Habitat maps (based on high-resolution multibeam backscatter, side scan sonar, and boulders) delineating sensitive benthic habitat areas should be provided to vessel operators to facilitate avoidance of these areas.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 25	C	Anchoring	During cable installation, anchor lines should be extended to the extent practicable to minimize the number of times the anchors must be raised and lowered to reduce the amount of habitat disturbance.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 26	C	Anchoring	Vessels must remain stationary, and dynamic positioning systems (DPS) or mid-line buoys on anchor chains should be required to minimize impacts on benthic habitats.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 27	C	Vessel Anchoring Plan	Results from SouthCoast Wind's comprehensive vessel anchoring plan should include information on how EFH CRs # 22-24 will be implemented into anchoring activities for the Lease Area and entirety of Brayton Point ECC and provided to NMFS HESD at NMFS.GAR.HESDoffshorewind@noaa.gov prior to construction to determine if additional CRs are needed.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 28	C	Scour protection material	Use natural or engineered stone of consistent grain size that mimics natural seafloor substrates (rock option proposed in the EFH assessment) to minimize the impacts of habitat conversion from cable protection and scour protection. At a minimum, any exposed surface layer should be designed and selected to provide three-dimensional structural complexity that creates a diversity of crevice sizes (e.g., mixed stone sizes) and rounded edges (e.g., tumbled stone), and be sloped such that outer edges match the natural grade of the seafloor. Should the use of concrete mattresses be necessary, use bioactive concrete (i.e., with bio-enhancing	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			admixtures) as the primary scour protection (e.g., concrete mattresses) or veneer of natural or engineered rounded stone with bio-enhancing admixtures should be overlaid to support biotic growth.		
EFH CR 29	C	Scour protection material	Plastics/recycled polyesters/net material (i.e., rock-filled mesh bags, fronded mattresses) should not be used as cable protection or scour protection outside temporary use (6 months or less) during construction activities.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 30	C	Temperate reef mitigation plan	Mitigate for permanent loss of temperate reefs within the Southern New England HAPC resulting from installation of the Brayton Point ECC and the use of cable protection. Specifically, the mitigation plan should identify (i) type of cable protection used between KP segments 76-84; (ii) estimated extent of area affected by installation of cable protection; and (iii) a plan outlining specifically how permanent impacts on temperate reefs between KP 84 and KP 76 will be offset/compensated. The mitigation plan should be provided to NMFS HESD atNMFS.GAR.HESDoffshorewind@noaa.gov for a 60 day review and comment prior to installation of cable protection.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 31	C	Marine debris removal	Retain and discard to an upland facility any debris encountered during site preparation grapnel runs. Do not abandon debris in place or return debris overboard.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 32	C	Suction bucket foundations	Suction bucket foundations should be installed where feasible to minimize acoustic effects on EFH and Atlantic cod spawning.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 33	C	Noise Mitigation Plan	The use of noise mitigating measures should be required during pile driving construction in the nearshore and offshore project areas, including the use of soft start procedures and the deployment of noise dampening equipment such as bubble curtains or double-bubble curtains.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 34	C	Fish Kill Notification Plan	Notify NMFS HESD within 24 hours of any evidence of a fish kill observed during construction activity. Notification should be provided to NMFS HESD at NMFS.GAR.HESDoffshorewind@noaa.gov along with contingency plans to resolve the issue. a) During occurrences of at least 10 dead non-ESA-listed fish observed within established shutdown or clearance zones, Protected Species Observers (PSOs) or project staff should collect images and representative samples of different sized cohorts from each species present for subsequent necropsies. Depending on the magnitude of the observed occurrence, PSOs should aim to collect up to 30 individuals, representative of the observed size range of each species, if less than 30 individuals are observed for any one species then all individuals should be collected. Collected images and necropsy results should be shared with NMFSHESD at NMFS.GAR.HESDoffshorewind@noaa.gov. b) If dead non-ESA-listed fish are observed repeatedly within established shutdown or clearance zones in association with pile driving activities, and necropsies find evidence of construction-related trauma and/or mortality (acoustic trauma, barotrauma, etc.), further investigations should be required to understand the underlying mechanism resulting in mortality. Specifically, if more than 100 individuals are observed in a single occurrence, or cumulatively reported across multiple shutdown or clearance zones, subsequent pile driving activities should be monitored in-situ. Potential techniques include the use of ROVs or BRUVs. c) A contingency plan outlining in-situ monitoring techniques and additional proposed mitigation measures should be provided with notification of a fish kill that meets or exceeds the threshold of more than 100 individuals as described above. A draft contingency plan should be developed prior to commencement of pile driving activities and adapted as needed based on conditions in the field. Monitoring results should be provided to NMFS HESD at NMFS.GAR.HESDoffshorewind@noaa.gov. Additional recommendations may be provided based on our review of monitoring results.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 35	Pre-C, C	Minimization to impacts on benthic habitat	Locate the Brayton Point ECC onshore (Alternative C in the EIS) to avoid adverse impacts on the Narragansett Bay Estuary and associated sensitive benthic habitats, including, HAPC for juvenile Atlantic cod, temperate reefs, and sensitive life stages for federally managed species that rely on the Sakonnet River and Mount Hope Bay.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 36	C	Microsite cables	Microsite the Brayton Point ECC (between KP segments 31 - 41) to avoid and minimize impacts on sensitive benthic features. Habitat maps (based on high-resolution multibeam backscatter, side scan sonar, and boulders) delineating sensitive habitat areas should be	Benthic, Finfish, Invertebrates, and	BOEM, BSEE, and NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			provided to vessel operators to facilitate avoidance of these areas.	Essential Fish Habitat	
EFH CR 37	Pre-C, C	Temperate reef mitigation plan	Mitigate for permanent loss of temperate reefs at the mouth of the Sakonnet River resulting from installation of the Brayton Point ECC between KP segments 33-35, and 37-42. Specifically, the mitigation plan should identify (i) type of cable protection used between KP segments listed above; (ii) estimated extent of area affected by installation of cable and cable protection; and (iii) a plan outlining specifically how permanent impacts on temperate reefs between KP segments listed above will be offset/compensated. The mitigation plan should be provided to NMFS HESD at NMFS.GAR.HESDoffshorewind@noaa.gov for a 60 day review and comment prior to installation of Brayton Point ECC and cable protection.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 38	Pre-C, C	Benthic mitigation plan	Mitigate for permanent loss of rocky habitats (pebble-gravel, cobble, boulder, and Crepidula spp. beds with/without attached macroalgae) within juvenile Atlantic cod and summer flounder HAPC in the Sakonnet River and Mount Hope Bay resulting from the installation of the Brayton Point ECC and the use of cable protection between KP segments 0-2, 6-10, 15-19, 20-27, and 33-35. Specifically, the mitigation plan should identify (i) type of cable protection used between KP segments listed above; (ii) estimated extent of area affected by installation of cable and cable protection; and (iii) a plan outlining specifically how permanent impacts on juvenile cod HAPC between the KP segments listed above will be offset/compensated. The mitigation plan should be provided to NMFS HESD at NMFS.GAR.HESDoffshorewind@noaa.gov for a 60 day review and comment prior to installation of Brayton Point ECC and cable protection.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 39	C	Landfall option	Require the use of the eastern shoreline option for the sea-to-shore transition of the Brayton Point ECC to Brayton Point to avoid the biogenic habitats (i.e., tube-building polychaete beds) at the western shoreline landfall.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 40	C	Microsite cables	Microsite the Brayton Point ECC to avoid important biogenic habitats (i.e., tube-building polychaete beds) in Mount Hope Bay. Targeted video and/or still imagery must be conducted in Mount Hope Bay to delineate the extent of biogenic habitats to inform micrositing within the cable corridor. Compensatory mitigation should occur for unavoidable permanent impacts from habitat conversion.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 41	Pre-C, C	Minimization to impacts on benthic habitats	Undertake sampling for contaminated sediments in Mount Hope Bay throughout the project area, including along the cable route and the HDD exit pits prior to commencement of seabed preparation and cable installation. Results of the sediment sampling should be provided to NMFS HESD for review to determine if any additional EFH CRs are warranted.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	USACE and NMFS
EFH CR 42	C	Trench avoidance in open nearshore/ estuarine waters	Use confined dredging with a closed clamshell/environmental bucket dredge for excavation at the HDD exit pits in areas that contain elevated levels of contaminants. Dispose of all excavated material at a suitable upland location, and backfill the HDD exit pits with suitable, clean material.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	USACE and NMFS
EFH CR 43	C	In-water work time restrictions: estuarine/ inshore (back bay waters)	Avoid in-water work including seabed preparation, cable installation, HDD pit excavation, cable protection installation, and other extractive or turbidity/sediment generating activities from January 15 through October 14 of any year to minimize impacts on winter flounder early life stages (eggs, larvae) in the nearshore waters to depths of 5 m, diadromous fish migrations, and shellfish.	Finfish, Invertebrates, and Essential Fish Habitat	USACE and NMFS
EFH CR 44	Pre-C, C	Minimization to impacts on benthic habitats	In all inshore/estuarine habitats where seafloor preparation and cable installation activities will occur, impacts on benthic habitats should be avoided and minimized through the use of HDD with confined dredging of excavation pits.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	USACE and NMFS
EFH CR 45	C	Anchoring	Anchoring associated with cable installation for the Brayton Point ECC should be consistent with the Project's easements. Consultation should be re-initiated for any anchoring activities that occur outside the easement.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 46	Pre-C	Frac-out plans	Frac-out plans should be developed for all areas where HDD is proposed to be used. A copy of the final plan should be provided to NMFS HESD at NMFS.GAR.HESDoffshorewind@noaa.gov prior to construction.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
EFH CR 47	Pre-C	Shellfish survey	A shellfish survey should be conducted prior to the commencement of dredging at all the HDD exit pits to identify high densities of shellfish. Shellfish beds that are identified should be relocated in coordination with Rhode Island Department of Environmental Management (RIDEM) and Massachusetts Division of Marine Fisheries (MA DMF) prior to commencement of in-water work.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 48	Pre-C	Benthic and Fisheries Habitat Monitoring Plans	We recommend the Monitoring Plans (Fisheries and Benthic) be updated to include the following: a) Pre-construction/baseline monitoring for a minimum of three years prior to any construction activities and continue annually for a minimum of five years post construction. This is particularly relevant to the fisheries monitoring surveys and the cable-associated physical disturbance survey. b) Expansion of the sexual maturity staging and spawning condition lab investigation to include Atlantic cod. Deceased cod should be collected, opportunistically, from the ventless trap and trawl surveys to better understand the spawning conditions present within the project area. c) Expand the number of cable segment replicates in the hard-bottom novel surfaces survey. Specifically, include at least three segments for each type of material used for cable armoring (if multiple types of materials are used for cable armoring) replicated across four distinct areas where the project proposes the use of cable armoring; inter-array cables, offshore export cable, and inshore export cable areas including three armored segment survey stations within both Narragansett Bay and Rhode Island Sound. If cable armoring is used in Mt. Hope Bay, one of the Narragansett Bay sites should be within Mt. Hope Bay. d) Invasive species (e.g., Didemnum vexillum) monitoring as a discrete data analysis component within both the hard-bottom-novel surfaces and cable-associated physical disturbance surveys to track the fragmentation and spread of invasive and non-native species across the lease as a result of project development. e) Project-wide collection of acoustic data (multibeam bathymetry and backscatter and side scan sonar) post-construction to measure the total area subject to physical change as a result of lease development. Post-construction acoustic surveys should be able to answer 1.) How much soft-bottom habitat across the lease has been converted to hard bottom; 2.) How much hard-bottom habitat across the lease has been converted to soft-bottom; 3.) How much natural hard-bottom habitat across the lease has been converted into man-made hard-bottom; 4.) How much total man-made hard bottom has been introduced into the project area (Lease Area and OECC); 5.) How much hard-bottom habitats have been impacted (i.e., relocated, fragmented, reduced in complexity, etc.) by the project compared with pre-construction surveys.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 49	Pre-C, C, O&M, D	In-situ Monitoring Program	Develop an in situ project specific monitoring program to address impacts of the operation of the SouthCoast Wind project on EFH and federally managed species. This monitoring recommendation is consistent with principles outlined in NOAA's Mitigation Policy for Trust Resources which highlights the use of the best available scientific information, such as results of surveys and other data collection efforts when existing information is not sufficient for the evaluation of proposed actions and mitigation, or when additional information would facilitate more effective or efficient mitigation recommendations. Incorporation of this monitoring recommendation would further align the monitoring efforts at SouthCoast Wind with the NOAA Fisheries and BOEM Federal Survey Mitigation Strategy which has evaluation and integration of wind energy monitoring studies with NOAA Fisheries surveys as a primary goal. The project specific, in-situ, monitoring program should measure the stressors created by project operation on the ecosystem from operational noise, electromagnetic fields (EMF), wind wake effects, and the presence of structures. Studies should also evaluate the biological effects of those stressors on commercially important species in the project area such as American lobster (*Homarus americanus*), Atlantic cod, Atlantic sea scallops (*Placopecten magellanicus*), black sea bass (*Centropristis striata*), hard clam (*Mercenaria mercenaria*), Jonah crab (*Cancer borealis*), monkfish (*Lophius americanus*), scup, skates, summer flounder, channeled whelk (*Busycotypus canaliculatus*) and knobbed whelk (*Busycon carica*). Monitoring plans should include the collection of a minimum of three years of baseline data, during construction, and a minimum of five years of post-construction data collection. Plans should be incorporated into a comprehensive monitoring strategy and be provided to NOAA Fisheries GARFO and NEFSC for review and comment within 90 days of ROD issuance. A response to NOAA Fisheries comments should be provided. These monitoring studies should be developed in partnership with NOAA Fisheries and other scientific institutions to aid in addressing the following questions: a) How far do effects on sound pressure, particle motion, and substrate vibration extend from the individual WTGs and the SouthCoast Wind Farm collectively? How far do effects on sound pressure, particle motion, and substrate vibration extend from the individual WTGs and the SouthCoast Wind Farm collectively? i. What effect do these operational noise effects have on the distribution of larvae for species with designated EFH in the project area and prey for these species (i.e., sand lance)? b) What is the spatial distribution of the EMF emissions around inter-array and export cables? The EMF study for the export cables should include measures to monitor EMF emissions from the inter-array cables and the export cables and address the following: i. What is the behavioral response to the altered EMF of fisheries resource species/life stages with known EMF-sensitivity? ii. Do the inter-array and export cables create a physical barrier (either from the presence of structure or from EMF exposure) to mobile benthic species, particularly whelks and Jonah crab	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			c) How far does the marine and atmospheric wind wake extend from the SouthCoast Wind Farm during operation? (See EFH CR#3) i. What are the effects on physical water column properties, primary and secondary production, and larval dispersal for species with designated EFH in the project area?		
EFH CR 50	C, O&M, D	Spill preventative measures	Require the implementation of preventive measures to reduce the risk of contaminant emissions or accidental release of chemicals. Such measures may include backup systems, secondary containments, closed-loop systems, and/or recovery tanks.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 51	C, O&M	Anti-corrosion protection measures	Any anti-corrosion protection methods or systems proposed should be identified. If sacrificial anodes are used, Al anodes should be selected over Zn anodes. Any application of anti-corrosion coatings should be allowed to cure fully on land, and BMPs for reducing spills should be implemented if reapplied offshore.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
EFH CR 52	C	Reinitiation of consultation	The EFH consultation should be reinitiated a) If the proposed action deviates in any way from what is described in the EFH assessment for Project 1 and/or Project 2; b) Once data is collected and processed for IAC routes; c) Prior to the construction and installation of Project 2, including activities associated with the construction and operation of the Falmouth contingency cable; d) Prior to decommissioning WTGs to ensure that the impact to EFH as a result of the decommissioning activities have been fully evaluated and minimized to the extent practicable. Pre-consultation coordination related to decommissioning should occur at least five years prior to proposed decommissioning.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat	BOEM, BSEE, and NMFS
FWCA CR 1	C, O&M, D	Fish and Wildlife Coordination Act (FWCA): Scientific Surveys	The lessee should be required to mitigate the major impacts on NOAA Fisheries scientific surveys consistent with NOAA Fisheries-BOEM Federal Survey Mitigation Strategy - Northeast U.S. Region. SouthCoast Wind's plans to mitigate these impacts at the project and regional levels should be provided to NOAA Fisheries for review and approval prior to BOEM's decision on its acceptance. Mitigation is necessary to ensure that NOAA Fisheries can continue to accurately, precisely, and timely execute our responsibilities to monitor the status and health of trust resources.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat; Commercial Fisheries and For-Hire Recreational Fishing	USACE and NMFS
FWCA CR 2	C	FWCA: Notification of location of relocated boulders, created berms, and scour protection	Locations of relocated boulders, created berms, and scour protection, including cable protection measures (i.e., concrete mattresses) should be provided to NOAA Fisheries, all other federal agencies with maritime jurisdiction, and the public as soon as possible to help inform all interested parties of potential gear obstructions.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat; Commercial Fisheries and For-Hire Recreational Fishing	USACE and NMFS
FWCA CR 3	C, O&M, D	FWCA: Whelk and hard clam survey plan	A whelk and hard clam survey plan should be developed for review and comment by NMFS. This survey may be incorporated as part of the Fisheries Monitoring Plan for the project. The survey should specifically investigate the potential changes in distribution and abundance of the species throughout the project area, pre- and post- development with an emphasis on the impacts within the inshore portion of the OECC within Narragansett Bay. The survey should focus on specific impact producing factors and the in-situ responses to those factors by individuals. Of particular concern, is the creation of artificial boundaries (i.e., EMF exposure from the OECC, berms created from scour protection, etc.) that may limit the movement of the species, the fragmentation of contiguous hard clam beds, and the biological response of hard clams to EMF exposure. The plan should be provided to NMFS HESD at NMFS.GAR.HESDoffshorewind@noaa.gov for a 60 day review and comment as soon as possible and at least 120 days prior to commencement of construction.	Benthic, Finfish, Invertebrates, and Essential Fish Habitat; Commercial Fisheries and For-Hire Recreational Fishing	USACE and NMFS
Draft NMFS Biological Opinion Reasonable and Prudent Measures dated October 24, 2024[2]					

[2] On October 24, 2024, NMFS provided draft RPMs to BOEM, USACE, BSEE and EPA for review as part of the ESA Section 7 consultation process for the SouthCoast Wind project. ESA Section 7 consultation was still ongoing at the time preparation of the FEIS was completed. The Lessee must adhere to the Biological Opinion, including the finalized RPMs and implementing terms and conditions, issued by NMFS for the SouthCoast Wind project.

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
RPM 1	C	WTG and OSP installation	Effects on ESA-listed species must be minimized and monitored during WTG and OSP foundation installation.	ESA-listed Fish, Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS
RPM 2	C	UXO detonation	Effects to ESA-listed species must be minimized and monitored during UXO/MEC detonations.	ESA-listed Fish, Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS
RPM 3	O&M	Hydrodynamic monitoring	Effects to North Atlantic right whales from hydrodynamic effects (wakes) around foundations must be monitored.	Marine Mammals	BOEM, BSEE, and NMFS
RPM 4	C, O&M, D	Onsite observation and reporting	Effects to, or interactions with, ESA-listed species must be properly documented during all phases of the proposed action, and all incidental take must be reported to NMFS GARFO.	ESA-listed Fish, Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS
RPM 5	C	Review of plans	Plans must be prepared that describe the implementation of activities and/or monitoring protocols for which the details were not available at the time this consultation was completed. All required plans must be submitted to NMFS GARFO in advance of the applicable activity with sufficient time for review, comment, and any required concurrence.	ESA-listed Fish, Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS
RPM 6	C, O&M, D	Onsite observation and inspection	BOEM, BSEE, NMFS OPR, and USACE must exercise their authorities to assess and ensure compliance with the implementation of measures to avoid, minimize, monitor, and report incidental take of ESA-listed species during activities described in this Opinion. On-site observation and inspection by appropriate agency personnel must be allowed to gather information on the implementation of measures, and the effectiveness of those measures, to minimize and monitor incidental take during activities described in this Opinion, including its Incidental Take Statement.	ESA-listed Fish, Marine Mammals, Sea Turtles	BOEM, BSEE, and NMFS
DOD Measures Resulting from Military Aviation and Installation Assurance Siting Clearinghouse Review dated August 10, 2022					
1	Pre- O&M and O&M	NORAD notification and Radar adverse impact management (RAM)	1) The Lessee will notify NORAD 30-60 days ahead of project completion and when the project is complete and operational for RAM scheduling. 2) The Lessee will contribute funds ($80,000) toward the execution of the RAM. 3) The Lessee will curtail when necessary for National Security or Defense Purposes as described in the agreement executed between BOEM and the Lessee for lease of the Project site.	Other uses (Military Use)	BOEM, BSEE, DoD
2	Pre- O&M and O&M	Distributed optical fiber sensing	BOEM will require that the Lessee provide information regarding deployment of distributed fiber-optic sensing technology to facilitate a Department of the Navy risk assessment and will require the Lessee to mitigate risk to national security, if identified.	Other uses (Military Use)	BOEM, BSEE, DoD/DON

[a] Pre-C = prior to construction; C = construction; O&M = operations and maintenance; D = Decommissioning

AMP = alternative monitoring plan; ASLF = ancient submerged landform feature; BiOP = biological opinion; BOEM = Bureau of Ocean Energy Management; BSEE = Bureau of Safety and Environmental Enforcement; CFR = code of federal regulations; COP = Construction and Operations Plan; dB = decibel; DMA = Dynamic Management Area; DOI = Department of the Interior; DPS = distinct population segment; ESA = Endangered Species Act; GPR = global pocket reader; GPS = global positioning system; HPTP = Historic Property Treatment Plan; HVAC = high-voltage alternating current; HVDC = high-voltage direct current; IHA = Incidental Harassment Authorization; IOOS = Integrated Ocean Observing System; ITA = incidental take authorization; ITS = incidental take statement; JPEG = joint photographic experts group; km = kilometer; km/hr = kilometer per hour; LOA = Letter of Authorization; mph = mile per hour; MMPA = Marine Mammal Protection Act; NARW = North Atlantic right whale; NAVTEX = Navigational Telex; NCEI = National Centers for Environmental Information; NMFS = National Marine Fisheries Service; NOAA = National Oceanic and Atmospheric Administration; NRHP = National Register of Historic Places; OCS = Outer Continental Shelf; OSP = offshore substation platform; PAM = passive acoustic monitoring; PDM = pile-driving monitoring; PIT = passive integrated transponder; PSO = protected species observer; RPM = Reasonable and Prudent Measure; SFVP = Sound Field Verification Plan; SMA = Seasonal Management Area; STDN = Sea Turtle Disentanglement Network; TIFF = tag image file format; USACE = United States Army Corp of Engineers; USCG = United States Coast Guard; USFWS = United States Fish and Wildlife Service; VHF = Very High Frequency; WTG = wind turbine generator

G.3 Additional Mitigation and Monitoring Measures

Table G-2 identifies agency-proposed mitigation measures that have been proposed to mitigate and/or monitor potential impacts from the Project. The paragraphs below provide additional information regarding the mitigation measures.

Table G-3. Additional Mitigation and Monitoring Measures

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
BOEM-Proposed Air Quality Mitigation Measures					
AQ-1	C, O&M, D	Engines that meet or exceed emission control requirements	Use engines manufactured and installed to meet or exceed emission control requirements. Engine manufacturers will incorporate pollution control measures into their designs. Techniques used could include: ensuring complete combustion in the engines, by control of the combustion air, controlling fuel flow, ensuring complete mixing, and staging combustion; avoiding hot spots in the combustion process that can form NO_X, by staging combustion, injecting water, recirculating flue gas, and otherwise cooling the system; and using post- combustion controls to remove air pollutants after they have formed, by adding particulate filters, oxidation catalysts, and selective catalytic reduction systems.	Air Quality	Best practice – not an enforceable measure
AQ-2	C, O&M, D	Vessel engines that meet or exceed applicable marine engine standards	Vessel engines will use a combination of combustion and post-combustion controls to meet or exceed applicable marine engine standards, including: The International Convention for the Prevention of Pollution from Ships (MARPOL) Annex VI (for foreign vessels); 40 CFR Part 89 (for Tier 1 and 2 domestic marine diesel engines smaller than 37 kW); Control of Emissions from Marine Compression-Ignition Engines; 40 CFR Part 94 (for Tier 1 and 2 domestic marine diesel engines larger than 37 kW); and Control of Emissions from New and In- Use Marine Compression-Ignition Engines and Vessels, 40 CFR Part 1042 (for Tier 3 and 4 domestic marine diesel engines). On-road engines, nonroad engines, and aircraft engines will meet or exceed similar standards.	Air Quality	Best practice – not an enforceable measure
AQ-3	C, O&M, D	Best available engines/fuels	Use the best available engines/fuels. Construction vessels will be supplied by contractors for temporary use on the Project. For O&M, SouthCoast Wind can specify the vessel used through long-term contracting or outright purchase. Nonroad engine emissions will be minimized using engines compliant with 40 CFR 1039, Control of Emissions from New and In-Use Nonroad Compression-Ignition Engines, i.e., "Tier 4" engines, where practicable.	Air Quality	Best practice – not an enforceable measure
AQ-4	C, O&M, D	Marine diesel fuel will comply with the fuel sulfur limit of 15 ppm	Marine diesel fuel will comply with the fuel sulfur limit of 15 ppm per 40 CFR 80, which is the same limit as onshore ULSD. For heavier residual fuel oils used in Category 2 and Category 3 engines, and for engines on foreign vessels, the Project will comply with the fuel oil sulfur content limit of 1,000 ppm set in MARPOL VI and corresponding USEPA regulations. Nonroad engines will use ULSD. The use of clean fuels will minimize emissions from fuel impurities and allow for cleaner combustion.	Air Quality	Best practice – not an enforceable measure
AQ-5	Pre-C, C, O&M, D	BMPs, innovative tools and/or technologies to minimize emissions from vessel operations	Implement BMPs and investigate the use of innovative tools and/or technologies to minimize air emissions from vessel operations. Specifically, SouthCoast Wind will optimize construction and O&M activities to minimize vessel operating times and loads. This will include weather monitoring, forecasting, and Project tracking to minimize emissions resulting from non-productive time, and incentives for contractor fuel savings.	Air Quality	Best practice – not an enforceable measure
AQ-6	Pre-C, C, O&M, D	Meet or exceed permit requirements and comply with all applicable air quality regulatory requirements	Air permit requirements will be met or exceeded, and SouthCoast Wind will comply with all applicable air quality regulatory requirements. A key element will be obtaining the OCS air permit. SouthCoast Wind will comply with other air- related regulatory requirements by using engines manufactured and maintained in compliance with the appropriate standards, which include New Source Performance Standards, National Emissions Standards for Hazardous Air Pollutants, and federal standards for nonroad and marine diesel engines. If onshore stationary equipment triggers any requirement to obtain a Massachusetts or Rhode Island air permit, as applicable (including obtaining coverage under a general permit), SouthCoast Wind will obtain the required permit.	Air Quality	USEPA and state (Massachusetts or Rhode Island, as applicable)
AQ-7	Pre-C	Document in OCS air permit compliance with air quality requirements	Any required OCS air permit will address documentation of compliance with ambient air standards, documentation of no adverse impact on air quality related values at Class I Areas, control technology review, and emission offsets.	Air Quality	USEPA and state (Massachusetts or Rhode Island, as applicable)
AQ-8	O&M	Use SF_6-free switchgear	This mitigation measure requires that the applicant use SF_6-free switchgear. BOEM is proposing additional mitigation requirements to minimize SF_6 emissions in the event that the applicant is not able to use SF_6-free switch gear. The additional mitigation is as follows:	Air Quality	BOEM

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			• Follow manufacturer recommendations for limiting leaks and for service and repair of the affected breakers and switches. • Perform repairs promptly when significant leaks are detected. • Conduct visual inspections of the switchgear and monitoring equipment according to manufacturer recommendations. • Create alarms based on the pressure readings in the breakers and switches, so leaks can be detected when substantial SF_6 leakage occurs. Upon a detectable pressure drop that is greater than 10% of the original pressure (accounting for ambient air conditions), perform maintenance to fix seals as soon as feasible. If an event requires removal of SF_6, the affected major component(s) will be replaced with new component(s). • Capture and recycle any SF_6 removed from breakers and switches during maintenance. Keep a log of all detected leaks and maintenance procedures potentially affecting SF_6 emissions from circuit breakers/switches.		
BOEM-Proposed Scenic and Visual Mitigation Measures					
SV-1	C, O&M	Scenic and Visual Impact Monitoring Plan	In coordination with BOEM, SouthCoast Wind will prepare and implement a scenic and visual resource monitoring plan that monitors and compares the visual effects of the wind farm during construction and O&M (daytime and nighttime) to the findings in the COP Visual Impact Assessment and verifies the accuracy of the visual simulations (photo and video). The monitoring plan should include monitoring and documenting the meteorological influences on actual wind turbine visibility over a duration of time from selected onshore key observation points, as determined by BOEM and the developer. In addition, SouthCoast Wind will include monitoring the operation of ADLS in the monitoring plan. SouthCoast Wind will monitor the frequency that the ADLS is operative documenting when (dates and time) the aviation warning lights are in the on position and the duration of each event. Details for monitoring and reporting procedures are to be included in the plan.	Scenic and Visual Resources	BOEM and BSEE
BOEM-Proposed Bird and Bat Mitigation Measures					
BRT-1	C, O&M	Compensatory Mitigation for Piping Plover, Red Knot, and Roseate Tern	At least 180 days prior to the start of commissioning of the first WTG, the Lessee must distribute a Compensatory Mitigation Plan to BOEM, BSEE, and the USFWS for review and comment. BOEM, BSEE, and USFWS will review the Compensatory Mitigation Plan and provide any comments on the plan to the Lessee within 60 days of its submittal. The Lessee must resolve all comments on the Compensatory Mitigation Plan to BOEM's and BSEE's satisfaction before implementing the plan and before commissioning of the first WTG. The Compensatory Mitigation Plan must provide compensatory mitigation actions to offset take of Piping Plover, Red Knot, and Roseate Tern for the first 5 years of WTG operation. The Compensatory Mitigation Plan must include a) detailed description of the mitigation actions; b) the specific location for each mitigation action; c) a timeline for completion of the mitigation measures; d) itemized costs for implementing the mitigation actions; e) details of the mitigation mechanisms (e.g., mitigation agreement, applicant-proposed mitigation; and f) monitoring to ensure the effectiveness of the mitigation actions in offsetting take.	Birds	BOEM, BSEE, USFWS
BOEM-proposed Nantucket Shoals Mitigation Measures					
NS-1	O&M	HVDC open-loop cooling system avoidance area	To minimize potential impacts on zooplankton from impingement and entrainment in offshore wind HVDC converter station open-loop cooling systems, no open-loop cooling systems would be permitted in the enhanced mitigation area of the Lease Area. No geographic restrictions on the offshore export cable corridor, nor the installation of an HVAC OSP are included in this mitigation measure.	Finfish and Invertebrates, Marine Mammals	BOEM and NMFS
NS-2	C, O&M	Pile-driven foundations only	Only monopile or piled jacket foundations may be used in the enhanced mitigation area, which would minimize the overall structure impact on benthic prey species.	Benthic Resources	BOEM and NMFS
NS-3	C	Vessel-strike avoidance	A real-time detection and reporting PAM system must be implemented during the construction period. The PAM system must operate in the enhanced mitigation area 24 hours per day. The system must be capable of detection of NARW vocalizations, report the detections to a PAM operator in near-real time, and share all detections with NMFS. Upon a confirmed detection of a NARW, all project construction and crew transfer vessels of all sizes must travel at 10 knots or less in a 10-square-kilometer area around the location of the detection. Speed restriction must remain in place until there are no PAM detections within 48 hours of implementation of the speed restrictions, or daily aerial surveys result in no NARW sightings within 48 hours of implementation of the speed restrictions.	Marine Mammals	BOEM, BSEE, and NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
NS-4	C	Pile-driving time of Year restriction in enhanced mitigation area	Pile driving within the enhanced mitigation area will occur only between June 1 to October 31 when NARW presence is at its lowest.	Marine Mammals, Sea Turtles, and Finfish and Invertebrates	BOEM, BSEE, and NMFS
NS-5	C	Pile driving shut down provisions in enhanced mitigation area	SouthCoast Wind will be required to implement a real-time monitoring system (PAM or aerial imagery) capable of detecting and localizing the direction of NARW calls in the enhanced mitigation area (Figure G-1). If directly measured or modeled Level A or Level B received sound levels from offshore pile driving occur within the enhanced mitigation area when NARW are detected, subsequent pile driving shall be suspended until NARWs are confirmed through acoustic monitoring or visual surveillance to be clear of the enhanced mitigation area for 48 hours.	Marine Mammals	BOEM, BSEE, and NMFS
Other Agency-Proposed Mitigation Measures					
OU-1	C, O&M	Federal survey mitigation implementation strategy for the Northeast U.S. region	BOEM is committed to working with NOAA toward a long-term regional solution to account for changes in survey methodologies because of offshore wind farms. NOAA Fisheries and BOEM published (December 2022) a Federal Survey Mitigation Strategy for the Northeast U.S. Region to address anticipated impacts of offshore wind energy development on NOAA Fisheries' scientific surveys. This strategy also defines stakeholders, partners, and other ocean users that will be engaged throughout the process and identifies potential resources for successful implementation. Activities described in the strategy are designed to mitigate the effect of offshore wind energy development on NOAA Fisheries surveys and is referred to as the Federal Survey Mitigation Program. The mitigation program will include survey-specific mitigation plans for each affected survey including both vessel and aerial surveys. The strategy is intended to guide the implementation of the mitigation program through the duration of wind energy development in the Northeast U.S. region.	Other Uses – Scientific Research and Surveys	BOEM, BSEE, and NMFS
OU-2	C, O&M	High-frequency radar system mitigation	High-Frequency Radar Interference Analysis and Mitigation The Lessee's Project has the potential to interfere with oceanographic high-frequency (HF) radar systems in the U.S. Integrated Ocean Observing System (IOOS®), which is managed by the IOOS Office within the National Oceanic and Atmospheric Administration (NOAA) pursuant to the Integrated Coastal and Ocean Observation System Act of 2009 (Pub. L. No. 111-11), as amended by the Coordinated Ocean Observation and Research Act of 2020 (Pub. L. No. 116-271, Title I), codified at 33 U.S.C. 3601–3610 (referred to herein as "IOOS HF-radar"). IOOS HF-radar measures the sea state, including ocean surface current velocity and waves in near real time. These data have many vital uses ("mission objectives"), including tracking and predicting the movement of spills of hazardous materials or other pollutants, monitoring water quality, and predicting sea state for safe marine navigation. The U.S. Coast Guard also integrates IOOS HF-radar data into its Search and Rescue systems. The Lessee's Project is within the measurement range of one IOOS HF-radar system operated by University of Massachusetts Dartmouth in Nauset, MA (NAUS), two IOOS HF-radar system operated by Woods Hole Oceanographic Institute (WHOI) and four IOOS HF-radar systems operated by Rutgers University in Amagansett, New York (AMAG), Block Island, RI Long-range SeaSonde (BLCK), Martha's Vineyard, MA (MVCO), and Nantucket, MA SeaSonde (NANT). 1.1 Mitigation Requirement Due to the potential interference with IOOS HF-radar and the risk to public health, safety, and the environment, the Lessee must mitigate unacceptable interference with IOOS HF-radar from the Project. The Lessee must mitigate interference before commissioning the first WTG or before blades start spinning, whichever is earlier, and interference mitigation must continue throughout operations and decommissioning until the point of decommissioning where all rotor blades are removed. Interference is considered unacceptable if, as determined by BOEM in consultation with NOAA's IOOS Office, IOOS HF-radar performance falls or may fall outside any of the specific radar systems' operational parameters or fails or may fail to meet IOOS's mission objectives. 1.2 Mitigation Review The Lessee must submit to BOEM documentation demonstrating how it will mitigate unacceptable interference with IOOS HF-radar systems in accordance with Section 1.1. The Lessee must submit this documentation to BOEM at least 120 days prior to commissioning the first WTG or the start of blades spinning, whichever is earlier. If, after consultation with the NOAA IOOS Office, BOEM deems the mitigation acceptable, the Lessee must conduct activities in accordance with the proposed mitigations. If, after consultation with NOAA IOOS Office, BOEM deems the mitigation unacceptable, the Lessee must resolve all comments on the documentation to BOEM's satisfaction. 1.3 Mitigation Agreement	Other Uses – Radar Systems	BOEM and NOAA IOOS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			The Lessee is encouraged to enter into an agreement with the NOAA IOOS Office to implement mitigation measures, and any such Mitigation Agreement may satisfy the requirement to mitigate unacceptable interference with IOOS HF-radar. The point of contact for the development of a Mitigation Agreement with the NOAA IOOS Office is the Surface Currents Program Manager, whose contact information is available at https://ioos.noaa.gov/about/meet-the-ioos-program-office/ and upon request from BOEM. If the parties reach a mitigation agreement, the Lessee must submit the agreement to BOEM. The Lessee may satisfy its obligations under Section 1.2 by providing BOEM with an executed Mitigation Agreement between the Lessee and NOAA IOOS. If there is any discrepancy between Section 1.2 and the terms of a Mitigation Agreement, the terms of the Mitigation Agreement will prevail. 1.4 Mitigation Data Requirements Mitigation required under Section 1.2 must address the following: 1.4.1 Before commissioning the first WTG or before blades start spinning, whichever is earlier, and continuing throughout the life of the Lessee's Project until the point of decommissioning when all rotor blades are removed, the Lessee must make publicly available via NOAA IOOS near real-time, accurate numerical telemetry of surface current velocity, wave height, wave period, wave direction, and other oceanographic data measured at the Lessee's Project locations selected by the Lessee in coordination with the NOAA IOOS Office. 1.4.2 If requested by the NOAA IOOS Office, the Lessee must share with IOOS accurate numerical time-series data of blade rotation rates, nacelle bearing angles, and other information about the operational state of each WTG in the Lease Area to aid interference mitigation. 1.5 Additional Notification and Mitigation 1.5.1 If at any time the NOAA IOOS Office or an HF-radar operator informs the Lessee that the Lessee's Project will cause unacceptable interference to an HF-radar system, the Lessee must notify BOEM of the determination and propose new or modified mitigation pursuant to Section 1.5.2 as soon as possible and no later than 30 days from the date on which the determination was communicated. 1.5.2 If a mitigation measure other than that identified in Section 1.2 is proposed, then the Lessee must submit information on the proposed mitigation measure to BOEM for its review and concurrence. If, after consultation with the NOAA IOOS Office, BOEM deems the mitigation acceptable, the Lessee must conduct activities in accordance with the proposed mitigations. The Lessee must resolve all comments on the documentation to BOEM's satisfaction, in consultation with the NOAA IOOS Office, prior to implementation of the mitigation.		
CF-2	C, O&M	Compensation for lost fishing income	The lessee shall implement a compensation program for lost income for commercial and recreational fishermen and other eligible fishing interests for construction and operations consistent with BOEM's draft guidance for Mitigating Impacts to Commercial and Recreational Fisheries on the Outer Continental Shelf Pursuant to 30 CFR 585 or as modified in response to public comment.	Commercial Fisheries and For-Hire Recreational Fisheries	BOEM
CF-3	O&M	Mobile gear friendly cable protection measures	Cable protection measures should reflect the pre-existing conditions at the site. This mitigation measure chiefly ensures that seafloor cable protection does not introduce new hangs for mobile fishing gear. Thus, the cable protection measures should be trawl-friendly with tapered/sloped edges. If cable protection is necessary in "non-trawlable" habitat, such as rocky habitat, then the lessee should consider using materials that mirror the benthic environment.	Commercial Fisheries and For-Hire Recreational Fisheries	BOEM
CF-4	C, O&M, D	Fishing Gear and Anchor Strike Incident Reporting	SouthCoast Wind will report fishing gear and anchor strike incidents that fall below or are not captured by the regulatory thresholds outlined in 30 CFR §§ 285.832 and 285.833. Reports will be filed annually during construction and decommissioning, and every 5 years during operations.	Commercial Fisheries and For-Hire Recreational Fisheries	BOEM, USCG
CF-5	C, O&M	Shoreside seafood business analysis	In addition to the compensation proposed by SouthCoast Wind, BOEM would require SouthCoast Wind to ensure that compensation includes losses to shoreside businesses. The lessee shall analyze the impacts on shoreside seafood businesses adjacent to ports. The shoreside seafood business analysis would be used to further supplement funds available for settling claims of lost (unrecovered) economic activity as a result of the SouthCoast Wind project.	Commercial Fisheries and For-Hire Recreational Fisheries	BOEM
NAV-1	C, O&M	Consult on aid to navigation impacts	Prior to cable installation, SouthCoast Wind will consult with USCG regarding potential impacts on federal aids to navigation from cable installation and maintenance.	Navigation	BOEM, BSEE
NAV-2	O&M	Operations Center	SouthCoast Wind will operate a 24-hour operations center with direct communications with the USCG.	Navigation	BOEM, BSEE

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
NAV-3	Pre-C, C, O&M, D	Mariner Communication and Outreach Plan	SouthCoast Wind will develop and implement a Mariner Communication and Outreach Plan that covers all project phases from pre-construction to decommissioning and that facilitates coordination with all mariners, including the commercial shipping industry, commercial and for-hire fishing industries, and other recreational users. The Mariner Communication and Outreach Plan will include the following components: e. During Project design, coordinating in-water construction activities to avoid and minimize disruptions; f. At least 90 days prior to commencing in-water construction activities in any construction season, consultation with stakeholders on an approximate schedule of activities and existing uses within the Project area. Make good faith efforts to accommodate those existing uses. The results of these good faith consultations can be summarized in a report and submitted to the federal agency(ies) prior to the start of each construction season; g. Following COP approval, notice of proposed changes which have the potential to impact fishing or maritime resources or activities; h. Notices to commence construction activities, conduct maintenance activities, and commence decommissioning; i. Status reports during construction with specific information on construction activities and locations for upcoming activities in the next 1–2 weeks; j. Post-construction notice of: (i) all cable protection measure locations (including protection type and charted location); (ii) any areas where the identified burial depth is less than target burial depth; and (iii) other obstructions to navigation created by the Project; and Post all notices described above to the Project website with information on how to opt-in for alerts.	Navigation	BOEM, BSEE
MA-1	C	Sand Wave Leveling and Boulder Clearance	Sand wave leveling and boulder clearance should be limited to the extent practicable. Best efforts should be made to microsite to avoid these areas.	Benthic Resources; EFH	BOEM, BSEE
MA-2	C, O&M	Long-Term Passive Acoustic Monitoring	The Lessee must conduct long-term monitoring of ambient noise, marine mammal and commercially important fish vocalizations in the Lease Area before, during, and following construction. The Lessee must conduct continuous recording at least 1 year before construction, during construction, initial operation, and for at least 3 but no more than 10 full calendar years of operation to monitor for potential noise impacts. The Lessee must meet with BOEM and BSEE at least 60 days prior to conclusion of the third full calendar year of operation monitoring (and at least 60 days prior to the conclusion of each subsequent year until monitoring is concluded) to discuss: 1) monitoring conducted to-date, 2) the need for continued monitoring, and 3) if monitoring is continued, whether adjustments to the monitoring are warranted. The instrument(s) must be configured to ensure that the specific locations of vocalizing NARW anywhere within the Lease Area could be identified, based on the assumption of a 10 km detection range for their calls. The lessee may execute the implementation of this condition through Option 1 or Option 2, as below. The timing requirement (i.e., monitoring for at least 3 but no more than 10 full calendar years of operation) will be reevaluated by BOEM and BSEE at the end of the third year and each year subsequently thereafter at the request of the Lessee (at a maximum frequency of requests of once per year). a. Option 1 - Lessee Conducts Long-term Passive Acoustic Monitoring. The Lessee must conduct PAM, including data processing and archiving following the Regional Wildlife Science Collaborative (RWSC) best practices to ensure data comparability and transparency. PAM instrumentation must be deployed to allow for identification of any NARW that vocalize anywhere within the Lease Area. The sampling rate (minimum 10 kHz) of the recorders must prioritize baleen whale detections but must also have a minimum capability to record noise from vessels, pile-driving, and WTG operation in the Lease Area. The system must be configured for continuous recording over the entire year. If temporal gaps in recording are expected, the Lessee must ensure that additional recorders can be deployed to fill gaps. The Lessee must use trawl-resistant moorings to ensure that instruments are not lost and must replace any lost instruments as soon as possible. The Lessee must also notify BOEM if this occurs. The Lessee must follow the best practices outlined in the RWSC best practices document, unless otherwise required through conditions of COP approval. The best practices include engaging with the RWSC, calibrating the instruments, running QA/QC on the raw data, following the templates for reporting species vocalizations, and preparing the data for archiving at National Centers for Ecological Information (NCEI). Although section III of the RWSC best practices document specifies steps for Section 106	Marine Mammals	BOEM, BSEE

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			compliance, the Lessee must instead follow the conditions outlined in Section 7.13 and the Section 106 Memorandum of Agreement. In terms of data processing, the Lessee must document the occurrence of whale vocalizations (calls of NARW, humpback, sei, fin, and minke whales, as well as odontocete clicks, as available based on sample rate) using automatic or manual detection methods. In addition, data must be processed with either manual or automatic detection software to detect vocalizations of spawning cod. The Lessee must submit a log of these detections as well as the detection methodology to BOEM (at renewable_reporting@boem.gov), BSEE (at protectedspecies@bsee.gov) and NMFS (at nmfs.pacmdata@noaa.gov) within 120 days following each recorder retrieval. All raw data must be sent to the NCEI Passive Acoustic Data archive on an annual basis and the Lessee must follow NCEI guidance for packaging the data and pay the fee. iv. Long-term Passive Acoustic Monitoring Plan. The Lessee must prepare and implement a Long-term PAM Plan under this option. No later than 120 days prior to instrument deployment and before any construction begins, the Lessee must submit to BOEM and BSEE (renewable_reporting@boem.gov and OSWsubmittals@bsee.gov) the Long-term PAM Plan that describes all proposed equipment (including number and configuration of instruments), deployment locations, mooring design, detection review methodology, and other procedures and protocols related to the required use of PAM. As the Lessee prepares the Long-term PAM Plan, it must coordinate with the RWSC. BOEM and BSEE will review the Long-term PAM Plan and provide comments, if any, on the plan within 45 days of its submittal. The Lessee may be required to submit a modified Long-term PAM Plan based on feedback from BOEM and BSEE. The Lessee must address all outstanding comments to BOEM's and BSEE's satisfaction and will need to receive written concurrence from BOEM and BSEE. If BOEM or BSEE do not provide comments on the Long-term PAM Plan within 45 days of its submittal, the Lessee may conclusively presume BOEM's and BSEE's 's concurrence with the Long-term PAM Plan. Option 2 – Economic and Other Contributions to BOEM's Environmental Studies Program. As an alternative to conducting long-term PAM in the Lease Area, the Lessee may opt to make an economic contribution to BOEM's Environmental Studies Partnership for an Offshore Wind Energy Regional Observation Network (POWERON) initiative on an annual basis and cooperate with the POWERON team to allow access to the Lease Area for deployment, regular servicing, and retrieval of instruments. The Lessee's economic contribution will provide for all activities necessary to conduct PAM within the Lease Area, such as vessel and staff time for regular servicing of instruments, QA/QC on data, data processing to obtain vocalizations of sound-producing species and ambient noise metrics, as well as long-term archiving of data at NCEI. At the Lessee's request, the amount of the economic contribution will be estimated by BOEM's Environmental Studies Program. The Lessee will also be invited to contribute to discussions about the scientific approach of the POWERON initiative via the RWSC. The Lessee may request temporary withholding of the public release (placement into the NCEI public data archive) of raw acoustic data collected within the Lease Area for up to 180 days after it is collected. During this temporary hold, the Lessee may be provided a copy of the raw PAM data that was collected in the Lease Area or ROW after it has been cleared for any national security concerns under the RWSC best practices document.		

G.4 Lessee Authorization and Permit Conditions

Table G-4 to be included with lessee authorization and permit conditions from CZMA, USEPA, NMFS, and USACE in the Final EIS if finalized.

Table G-4. Lessee authorization and permit conditions

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
Federal Consistency Conditions Issued [Date]					
Massachusetts Office of Coastal Zone Management Consistency Conditions Issued October 21, 2024					
1	Pre-C	Permitting	SCW Project 2 – SCW LLC shall obtain and provide to CZM the required signed final MassDEP Chapter 91 license (and associated Wetlands Protection Act Order of Conditions or Superseding Order of Conditions) for the offshore export cable in state waters with a	Multiple	MACZM

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			landfall site in Somerset, Massachusetts. SCW Project 2 proposes to use the same offshore export cable corridor assessed by MassDEP for the SCW Project 1 Chapter 91 License.		
Rhode Island Coastal Resources Management Council Consistency Conditions Issued December 19, 2023					
1	C	Cable installation	Regarding all export cable installation activity subject to the Council's federal consistency review authority, SouthCoast Wind Energy LLC shall use all reasonable efforts to locate and install export cables outside complex and sensitive benthic habitat areas and, where siting outside of such areas is not possible, use reasonable efforts to micro-site cable locations to minimize adverse impacts on pertinent coastal resources. In any circumstance, SouthCoast Wind Energy LLC is not required to act against its own business interests by taking every possible action to avoid impacts, incur unlimited costs, or take unlimited time in meeting this condition. Avoidance, minimization, and mitigation will reduce the reasonably foreseeable effects on Rhode Island coastal resources and uses, including effects on those resources and uses with the same characteristics, values, and resources as found in Rhode Island State Waters.	Benthic, Commercial Fisheries and For-Hire Recreational Fishing	RICRMC
2	C	Cable burial depth	In furtherance of using reasonable efforts to avoid and minimize impacts on complex and sensitive benthic habitat areas, SouthCoast Wind Energy LLC shall provide notice to the Council of locations where the target cable burial depth range of 3.2 feet to 13.1 feet has not been achieved and the locations of secondary cable protection (i.e., mattresses, rock bags, etc.). Such notice shall consist of a written description of the area and a map(s) sufficient to see details of the project cable burial paths in order to overlay with tow lines. At a minimum, the written description must include the cable burial depth achieved and a description of the surrounding benthic conditions. Notice shall be provided to the Council within 30 days of SouthCoast Wind completing the as-built survey for each export cable.	Benthic, Commercial Fisheries and For-Hire Recreational Fishing	RICRMC
3	C	Boulder relocation	Where applicable, SouthCoast Wind Energy LLC shall make all reasonable efforts to relocate boulders within the same area/environment and group boulders with nearby existing boulders. Furthermore, where boulders are relocated, SouthCoast Wind Energy LLC shall provide notice to the Council of the original boulder locations as well as the new boulder locations. Notice shall be the same as the notice requirement stated in Condition 2. The relocation/grouping of boulders with existing boulders will further avoid, minimize, and mitigate impacts on resource habitats and minimize the creation of new hangs for the fishing industry to the extent practicable.	Benthic, Commercial Fisheries and For-Hire Recreational Fishing	RICRMC
4	C	Cable installation	Cables shall be no further apart than necessary for installation, maintenance, and operational activities in order to minimize unnecessary impacts on coastal uses and resources.	Multiple	RICRMC
5	Pre-C	Fisheries and benthic research and monitoring plan	SouthCoast Wind Energy LLC shall conduct the fisheries research and monitoring plan and the benthic habitat research and monitoring plan that receive final approval from the Bureau of Ocean Energy Management as part of the Record of Decision approving SouthCoast Wind Construction and Operations Plan. Findings from each relevant monitoring plan shall be supplied to the Council on an annual basis once reports are available to SouthCoast Wind. This information will facilitate the Coastal Resources Management Council's continued monitoring of activities described in the Outer Continental Shelf (OCS) plans to make certain that activities continue to conform to both federal and State requirements.	Benthic, Commercial Fisheries and For-Hire Recreational Fishing	RICRMC
NMFS Proposed Incidental Take Regulations and Associated 5-year Letter of Authorization Issued [Draft Issued on June 27 2024]					
1	General Conditions	Pre-C, C, O&M, D	SouthCoast Wind must comply with the following general measures: a) A copy of any issued LOA must be in the possession of SouthCoast Wind and its designees, all vessel operators, visual protected species observers (PSOs), passive acoustic monitoring (PAM) operators, pile driver operators, and any other relevant designees operating under the authority of the issued LOA; b) SouthCoast Wind must conduct training for construction supervisors, construction crews, and the PSO and PAM team prior to the start of all construction activities and when new personnel join the work in order to explain responsibilities, communication procedures, marine mammal monitoring and reporting protocols, and operational procedures. A description of the training program must be provided to NMFS at least 60 days prior to the initial training before in-water activities begin. Confirmation of all required training must be documented on a training course log sheet and reported to NMFS Office of Protected Resources prior to initiating project activities; c) SouthCoast Wind is required to use available sources of information on North Atlantic right whale presence to aid in monitoring efforts. These include daily monitoring of the Right Whale Sighting Advisory System, consulting of the WhaleAlert	Marine Mammals	NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			app, and monitoring of the Coast Guard's Very High Frequency (VHF) Channel 16 to receive notifications of marine mammal sightings and information associated with any Dynamic Management Areas (DMA) and Slow Zones; d) Any marine mammal observation by project personnel must be immediately communicated to any on-duty PSOs and PAM operator(s). Any large whale observation or acoustic detection by any project personnel must be conveyed to all vessel captains; e) If an individual from a species for which authorization has not been granted or a species for which authorization has been granted but the authorized take number has been met is observed entering or within the relevant clearance zone prior to beginning a specified activity, the activity must be delayed. If an activity is ongoing and an individual from a species for which authorization has not been granted or a species for which authorization has been granted but the authorized take number has been met is observed entering or within the relevant shutdown zone, the activity must be shut down (i.e., cease) immediately unless shutdown would result in imminent risk of injury or loss of life to an individual, pile refusal, or pile instability. The activity must not commence or resume until the animal(s) has been confirmed to have left the clearance or shutdown zones and is on a path away from the applicable zone or after 30 minutes for all baleen whale species and sperm whales, and 15 minutes for all other species; f) In the event that a large whale is sighted or acoustically detected that cannot be confirmed as a non-North Atlantic right whale, it must be treated as if it were a North Atlantic right whale for purposes of mitigation; (7) For in-water construction heavy machinery activities listed in section 1(a), if a marine mammal is detected within or about to enter 10 meters (m) (32.8 feet (ft)) of equipment, SouthCoast Wind must cease operations until the marine mammal has moved more than 10 m on a path away from the activity to avoid direct interaction with equipment; g) All vessels must be equipped with a properly installed, operational Automatic Identification System (AIS) device and SouthCoast Wind must report all Maritime Mobile Service Identify (MMSI) numbers to NMFS Office of Protected Resources prior to use of any project vessels; h) By accepting a LOA, SouthCoast Wind consents to on-site observation and inspections by Federal agency personnel (including NOAA personnel) during activities described in this subpart, for the purposes of evaluating the implementation and effectiveness of measures contained within this LOA; and i) It is prohibited to assault, harm, harass (including sexually harass), oppose, impede, intimidate, impair, or in any way influence or interfere with a PSO, PAM operator, or vessel crew member acting as an observer, or attempt the same. This prohibition includes, but is not limited to, any action that interferes with an observer's responsibilities or that creates an intimidating, hostile, or offensive environment. Personnel may report any violations to the NMFS Office of Law Enforcement.		
2	Pre-C, C, O&M, D	Vessel Strike Avoidance	SouthCoast Wind must comply with the following vessel strike avoidance measures while in the specific geographic region unless a deviation is necessary to maintain safe maneuvering speed and justified because the vessel is in an area where oceanographic, hydrographic, and/or meteorological conditions severely restrict the maneuverability of the vessel; an emergency situation presents a threat to the health, safety, life of a person; or when a vessel is actively engaged in emergency rescue or response duties, including vessel-in distress or environmental crisis response. An emergency is defined as a serious event that occurs without warning and requires immediate action to avert, control, or remedy harm. Speed over ground will be used to measure all vessel speeds: a) Prior to the start of the Project's activities involving vessels, all vessel personnel must receive a protected species training that covers, at a minimum, identification of marine mammals that have the potential to occur in the specified geographical region; detection and observation methods in both good weather conditions (i.e., clear visibility, low winds, low sea states) and bad weather conditions (i.e., fog, high winds, high sea states, with glare); sighting communication protocols; all vessel strike avoidance mitigation requirements; and information and resources available to the project personnel regarding the applicability of Federal laws and regulations for protected species. This training must be repeated for any new vessel personnel who join the project. Confirmation of the vessel personnel training and understanding of the LOA requirements must be documented on a training course log sheet and reported to NMFS within 30 days of completion of training, prior to personnel joining vessel operations; b) All vessel operators, operating at any speed and regardless of their vessel's size, and dedicated visual observers must maintain a vigilant watch for all marine mammals and operators must slow down, stop their vessel, or alter course to avoid striking any marine mammal; (3) All transiting vessels operating at any speed must have a dedicated visual observer on duty at all times to monitor for marine mammals within a 180 degrees (°) direction of the forward path of the vessel (90° port to	Marine Mammals	NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			90° starboard) located at an appropriate vantage point for ensuring vessels are maintaining required separation distances. Dedicated visual observers may be PSOs or crew members, but crew members responsible for these duties must be provided sufficient training by SouthCoast Wind to distinguish marine mammals from other phenomena and must be able to identify a marine mammal as a North Atlantic right whale, other large whale (defined in this context as sperm whales or baleen whales other than North Atlantic right whales), or other marine mammals. Dedicated visual observers must be equipped with alternative monitoring technology (e.g., night vision devices, infrared cameras) for periods of low visibility (e.g., darkness, rain, fog, etc.). The dedicated visual observer must not have any other duties while observing and must receive prior training on protected species detection and identification, vessel strike avoidance procedures, how and when to communicate with the vessel captain, and reporting requirements in this subsection and LOA; c) At the onset of transiting and continuously thereafter, vessel operators and dedicated visual observers must monitor the U.S. Coast Guard VHF Channel 16, over which North Atlantic right whale sightings are broadcasted. At the onset of transiting and at least once every 4 hours, vessel operators and/or trained crew member(s) must also monitor the project's Situational Awareness System (if applicable), WhaleAlert, and relevant NOAA information systems such as the Right Whale Sighting Advisory System (RWSAS) for the presence of North Atlantic right whales; d) Prior to transit, vessel operators must check for information regarding the establishment of Seasonal and Dynamic Management Areas, Slow Zones, and any information regarding North Atlantic right whale sighting locations; e) All vessel operators must abide by vessel speed regulations (50 CFR 224.105). Nothing in this subsection exempts vessels from any other applicable marine mammal speed or approach regulations; f) All vessel operators, regardless of their vessel's size, must immediately reduce vessel speed to 10 knots (11.5 mph) or less for at least 24 hours when a North Atlantic right whale is sighted at any distance by any project-related personnel or acoustically detected by any project-related PAM system. Each subsequent observation or acoustic detection in the Project area shall trigger an additional 24-hour period. If a North Atlantic right whale is reported by project personnel or via any of the monitoring systems (see paragraph (b)(4)) within 10 km of a transiting vessel, that vessel must operate at 10 knots (11.5 mph) or less for 24 hours following the reported detection; g) In the event that a DMA or Slow Zone is established that overlaps with an area where a project-associated vessel is operating, that vessel, regardless of size, must transit that area at 10 knots (11.5 mph) or less; h) Between November 1st and April 30th, all vessels, regardless of size, must operate at 10 knots (11.5 mph) or less in the specified geographical region, except for vessels while transiting in Narragansett Bay or Long Island Sound; i) All vessels, regardless of size, must immediately reduce speed to 10 knots (11.5 mph) or less when any large whale (other than a North Atlantic right whale), mother/calf pairs, or large assemblages of non-delphinid cetaceans are observed within 500 m (0.31 mi) of a transiting vessel; j) If a vessel is traveling at any speed greater than 10 knots (11.5 mph) (i.e., no speed restrictions are enacted) in the transit corridor (defined as from a port to the Lease Area or return), in addition to the required dedicated visual observer, SouthCoast Wind must monitor the transit corridor in real-time with PAM prior to and during transits. If a North Atlantic right whale is detected via visual observation or PAM within or approaching the transit corridor, all vessels in the transit corridor must travel at 10 knots (11.5 mph) or less for 24 hours following the detection. Each subsequent detection shall trigger a 24-hour reset. A slowdown in the transit corridor expires when there has been no further North Atlantic right whale visual or acoustic detection in the transit corridor in the past 24 hours; k) All vessels must maintain a minimum separation distance of 500 m from North Atlantic right whales. If underway, all vessels must steer a course away from any sighted North Atlantic right whale at 10 knots (11.5 mph) or less such that the 500-m minimum separation distance requirement is not violated. If a North Atlantic right whale is sighted within 500 m of an underway vessel, that vessel must turn away from the whale(s), reduce speed and shift the engine to neutral. Engines must not be engaged until the whale has moved outside of the vessel's path and beyond 500 m; l) All vessels must maintain a minimum separation distance of 100 m (328 ft) from sperm whales and non-North Atlantic right whale baleen whales. If one of these species is sighted within 100 m (328 ft) of an underway vessel, the vessel must turn away from the whale(s), reduce speed, and shift the engine(s) to neutral. Engines must not be engaged until the whale has moved outside of the vessel's path and beyond 100 m (328 ft); m) All vessels must maintain a minimum separation distance of 50 m (164 ft) from all delphinid cetaceans and pinnipeds with an exception made for those that approach the vessel (e.g., bow-riding dolphins). If a delphinid cetacean or pinniped is sighted		

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			within 50 m (164 ft) of a transiting vessel, that vessel must turn away from the animal(s), reduce speed, and shift the engine to neutral, with an exception made for those that approach the vessel (e.g., bow-riding dolphins). Engines must not be engaged until the animal(s) has moved outside of the vessel's path and beyond 50 m (164 ft); n) All vessels underway must not divert or alter course to approach any marine mammal; and o) SouthCoast Wind must submit a Marine Mammal Vessel Strike Avoidance Plan 180 days prior to the planned start of vessel activity that provides details on all relevant mitigation and monitoring measures for marine mammals, vessel speeds and transit protocols from all planned ports, vessel-based observer protocols for transiting vessels, communication and reporting plans, and proposed alternative monitoring equipment in varying weather conditions, darkness, sea states, and in consideration of the use of artificial lighting. If SouthCoast Wind plans to implement PAM in any transit corridor to allow vessel transit above 10 knots (11.5 mph), the plan must describe how PAM, in combination with visual observations, will be conducted. If a plan is not submitted and approved by NMFS prior to vessel operations, all project vessels must travel at speeds of 10 knots (11.5 mph) or less. SouthCoast Wind must comply with any approved Marine Mammal Vessel Strike Avoidance Plan.		
3	C	WTG and OSP foundation installation	The following requirements apply to vibratory and impact pile driving activities associated with the installation of WTG and OSP foundations: a) Foundation pile driving activities must not occur January 1 through May 15 throughout the Lease Area. From October 16 through May 31, impact and vibratory pile driving must not occur at locations in SouthCoast's Lease Area within the North Atlantic right whale Enhanced Mitigation Area (NARW EMA; defined as 20 km (12.4 mi) of the 30-m (98-ft) isobath on the west side of Nantucket Shoals); b) Outside of the NARW EMA, foundation pile driving must not be planned for December; however, it may occur only if necessary to complete planned pile driving within a given year and with prior approval by NMFS and implementation of enhanced mitigation and monitoring in accordance with an approved Enhanced Mitigation and Monitoring Plan. SouthCoast Wind must notify NMFS in writing by September 1 of that year if circumstances are expected to necessitate pile driving in December; c) In the NARW EMA, SouthCoast must install foundations as quickly as possible and sequence them from the northeast corner of the Lease Area to the southwest corner such that foundation installation in positions closest to Nantucket Shoals are completed during the period of lowest North Atlantic right whale occurrence in that area; d) Monopiles must be no larger than a tapered 9/16-m diameter monopile design and pin piles must be no larger than 4.5-m diameter design. The minimum amount of hammer energy necessary to effectively and safely install and maintain the integrity of the piles must be used. Impact hammer energies must not exceed 6,600 kilojoules (kJ) for monopile installations and 3,500 kJ for pin pile installations; e) SouthCoast must not initiate pile driving earlier than 1 hour after civil sunrise or later than 1.5 hours prior to civil sunset unless SouthCoast submits and NMFS approves a Nighttime Pile Driving Monitoring Plan that demonstrates the efficacy of their low visibility visual monitoring technology (e.g., night vision devices, Infrared (IR) cameras) to effectively monitor the mitigation zones in low visibility conditions. SouthCoast must submit this plan or plans (if separate Daytime Reduced Visibility and Nighttime Monitoring Plans are prepared) at least 180 calendar days before foundation installation is planned to begin. SouthCoast must submit a separate Plan describing daytime reduced visibility monitoring if the information in the Nighttime Monitoring Plan does not sufficiently apply to all low-visibility monitoring. f) SouthCoast Wind must utilize a soft-start protocol at the beginning of foundation installation for each impact pile driving event and at any time following a cessation of impact pile driving for 30 minutes or longer; g) SouthCoast Wind must deploy, at minimum, a double-bubble curtain during all foundation pile driving; i. The double-bubble curtain must distribute air bubbles using an air flow rate of at least 0.5 m3 /(min*m). The double-bubble curtain must surround 100 percent of the piling perimeter throughout the full depth of the water column. In the unforeseen event of a single compressor malfunction, the offshore personnel operating the bubble curtain(s) must make adjustments to the air supply and operating pressure such that the maximum possible sound attenuation performance of the bubble curtain(s) is achieved. ii. The lowest bubble ring must be in contact with the seafloor for the full circumference of the ring, and the weights attached to the bottom ring must ensure 100-percent seafloor contact.	Marine Mammals	NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			iii. No parts of the ring or other objects may prevent full seafloor contact with a bubble curtain ring. iv. SouthCoast Wind must inspect and carry out maintenance on the noise attenuation systems prior to every pile driving event and prepare and submit a Noise Attenuation System (NAS) inspection/performance report. For piles for which Thorough SFV (T-SFV) is carried out, this report must be submitted no later than when the interim T-SFV report is submitted for the respective pile. Performance reports for all Abbreviated SFV (A-SFV) conducted for subsequent piles must be submitted with the weekly pile driving reports. All reports must be submitted by email to pr.itp.monitoringreports@noaa.gov h) SouthCoast Wind must utilize PSOs. Each monitoring platform must have at least three on-duty PSOs. PSOs must be located on the pile driving vessel as well as on a minimum of three PSO-dedicated vessels inside the NARW EMA June 1 through July 31 and outside the NARW EMA June 1 through November 30, and a minimum of four PSO-dedicated vessels within the NARW EMA August 1-October 15 and throughout the Lease Area May 16-31 and December 1-31 (if pile driving in December is deemed necessary and approved by NMFS); i) Concurrent with visual monitoring, SouthCoast Wind must utilize PAM operator(s), as described in a NMFS-approved PAM Plan, who must conduct real-time acoustic monitoring of marine mammals for 60 minutes before, during, and 30 minutes after completion of impact and vibratory pile driving for each pile. PAM operators must immediately communicate all detections of marine mammals to the Lead PSO, including any determination regarding species identification, distance, and bearing and the degree of confidence in the determination; j) To increase situational awareness prior to pile driving, the PAM operator must review PAM data collected within the 24 hours prior to a pile installation; k) The PAM system must be able to detect marine mammal vocalizations, maximize baleen whale detections, and detect North Atlantic right whale vocalizations up to a distance of 10 km (6.2 mi) and 15 km (9.3mi) during pin pile and monopile installation, respectively. NMFS recognizes that detectability of each species' vocalizations will vary based on vocalization characteristics (e.g., frequency content, source level), acoustic propagation conditions, and competing noise sources), such that other marine mammal species (e.g., harbor porpoise) may not be detected out to 10 km (6.2 mi) or 15 km (9.3 mi); l) SouthCoast Wind must submit a Passive Acoustic Monitoring Plan (PAM Plan) to NMFS Office of Protected Resources for review and approval at least 180 days prior to the planned start of foundation installation activities and abide by the Plan, if approved. m) SouthCoast Wind must establish clearance and shutdown zones, which must be measured using the radial distance from the pile being driven. All clearance zones must be monitored by PSOs for at least 60 minutes prior to monitoring prior to, during, and 30 minutes after each foundation installation and must be confirmed to be free of marine mammals for 30 minutes immediately prior to the beginning of soft-start procedures or vibratory pile driving. If a marine mammal (other than a North Atlantic right whale) is detected within or about to enter the applicable clearance zones during this 30-minute time period, vibratory and impact pile driving must be delayed until the animal has been visually observed exiting the clearance zone or until a specific time period has elapsed with no further sightings. The specific time periods are 30 minutes for all baleen whale species and sperm whales and 15 minutes for all other species; n) For North Atlantic right whales, any visual observation by a PSO at any distance, or acoustic detection within the 10-km (6.2-mi) (pin pile) and 15-km (9.32-mi) (monopile) PAM clearance and shutdown zones must trigger a delay to the commencement or shutdown of pile driving. Within the NARW EMA August 1- October 15 and throughout the Lease Area May 16-31 and December 1-31 (if pile driving in December is deemed necessary and approved by NMFS), for any acoustic detection within the North Atlantic right whale PAM clearance and shutdown zones or sighting of 1 or 2 North Atlantic right whales, SouthCoast Wind must delay commencement of or shutdown pile driving for 24 hours. For any sighting of 3 or more North Atlantic right whales, SouthCoast Wind must delay commencement of or shutdown pile driving for 48 hours. Prior to beginning clearance at the pile driving location after these periods, SouthCoast must conduct a vessel-based survey to visually clear the 10-km (6.2-mi) zone, if installing pin piles that day, or 15-km (9.32- mi) zone, if installing monopiles; o) If visibility decreases such that the entire clearance zone is not visible, at minimum, PSOs must be able to visually clear (i.e., confirm no marine mammals are present) the minimum visibility zone. The entire minimum visibility zone must be visible (i.e., not obscured by dark, rain, fog, etc.) for the full 60 minutes immediately prior to commencing impact and vibratory pile driving;		

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			p) If a marine mammal is detected (visually or acoustically) entering or within the respective shutdown zone after pile driving has begun, the PSO or PAM operator must call for a shutdown of pile driving and SouthCoast Wind must stop pile driving immediately, unless shutdown is not practicable due to imminent risk of injury or loss of life to an individual or risk of damage to a vessel that creates risk of injury or loss of life for individuals, or the lead engineer determines there is risk of pile refusal or pile instability. If pile driving is not shut down due to one of these situations, SouthCoast Wind must reduce hammer energy to the lowest level practicable to maintain stability; q) If pile driving has been shut down due to the presence of a marine mammal other than a North Atlantic right whale, pile driving must not restart until either the marine mammal(s) has voluntarily left the species-specific clearance zone and has been visually or acoustically confirmed beyond that clearance zone, or, when specific time periods have elapsed with no further sightings or acoustic detections. The specific time periods are 30 minutes for all non-North Atlantic right whale baleen whale species and sperm whales and 15 minutes for all other species. In cases where these criteria are not met, pile driving may restart only if necessary to maintain pile stability at which time SouthCoast Wind must use the lowest hammer energy practicable to maintain stability; r) SouthCoast Wind must submit a Pile Driving Marine Mammal Monitoring Plan to NMFS Office of Protected Resources for review and approval at least 180 days prior to planned start of foundation pile driving and abide by the Plan, if approved. SouthCoast Wind must obtain both NMFS Office of Protected Resources and NMFS Greater Atlantic Regional Fisheries Office Protected Resources Division's concurrence with this Plan prior to the start of any pile driving; s) SouthCoast Wind must perform T-SFV measurements during installation of, at minimum, the first three WTG monopile foundations, first four WTG pin piles, and all OSP jacket foundation pin piles; t) T-SFV measurements must continue until T-SFV of at least three consecutive monopiles or four consecutive pin piles demonstrate noise levels are at or below those modeled, assuming 10 decibels (dB) of attenuation. Subsequent T-SFV measurements are also required should larger piles be installed or if additional monopiles or pin piles supporting jacket foundations are driven that may produce louder sound fields than those previously measured (e.g., from higher hammer energy, greater number of strikes); i. T-SFV measurements must be made at a minimum of four distances from the pile(s) being driven along a single transect in the direction of lowest transmission loss (i.e., projected lowest transmission loss coefficient), including, but not limited to, 750 m (2,460 ft) and three additional ranges selected such that measurement of modeled Level A harassment and Level B harassment isopleths are accurate, feasible, and avoids extrapolation (i.e., recorder spacing is approximately logarithmic and significant gaps near expected isopleths are avoided). At least one additional measurement at an azimuth 90 degrees from the transect array at 750 m (2,460 ft) must be made. At each location, there must be a near bottom and mid-water column hydrophone (acoustic recorder); ii. If any of the T-SFV results indicate that distances to harassment isopleths were exceeded, then SouthCoast Wind must implement additional measures for all subsequent foundation installations to ensure the measured distances to the Level A harassment and Level B harassment threshold isopleths do not exceed those modeled assuming 10-dB attenuation. SouthCoast Wind must also increase clearance, shutdown, and/or Level B harassment zone sizes to those identified by NMFS until T-SFV measurements on at least three additional monopiles or four pin piles demonstrate distances to harassment threshold isopleths meet or are less than those modeled assuming 10-dB of attenuation. For every 1,500 m (4,900 ft) that a marine mammal clearance or shutdown zone is expanded, additional PSOs must be deployed from additional platforms/vessels to ensure adequate and complete monitoring of the expanded clearance and/or shutdown zone(s), with each PSO responsible for scanning no more than 120 degrees (°) out to a radius no greater than 1,500 m (4,900 ft). SouthCoast Wind must optimize the sound attenuation systems (e.g., ensure hose maintenance, pressure testing) to, at least, meet noise levels modeled, assuming 10-dB attenuation, within three monopiles or four pin piles, or else foundation installation activities must cease until NMFS and SouthCoast Wind can evaluate potential reasons for louder than anticipated noise levels. Alternatively, if SouthCoast determines T-SFV results demonstrate noise levels are within those modeled assuming 10-dB attenuation, SouthCoast may proceed to the next pile after submitting the interim report to NMFS; u) SouthCoast Wind also must conduct A-SFV, using at least one acoustic recorder (consisting of a bottom and mid-water column hydrophone) for every foundation for which T-SFV monitoring is not conducted. All A-SFV data must be included in weekly reports. Any indication that distances to the identified Level A harassment and Level B harassment threshold		

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			isopleths for marine mammals may be exceeded based on this abbreviated monitoring must be addressed by SouthCoast Wind in the weekly report, including an explanation of factors that contributed to the exceedance and corrective actions that were taken to avoid exceedance on subsequent foundations. SouthCoast Wind must meet with NMFS within two business days of SouthCoast Wind's submission of a report that includes an exceedance to discuss if any additional action is necessary; v) The SFV measurement systems must have a sensitivity for the expected sound levels from pile driving received at the nominal ranges throughout the installation of the pile. The frequency range of SFV measurement systems must cover the range of at least 20 hertz (Hz) to 20 kilohertz (kHz). The SFV measurement systems must be designed to have omnidirectional sensitivity so that the broadband received level of all pile driving exceeds the system noise floor by at least 10 dB. The dynamic range of the SFV measurement system must be sufficient such that signals are detected at each location, and the signals avoid poor signal-to-noise ratios for low amplitude signals and avoid clipping, nonlinearity, and saturation for high amplitude signals; w) SouthCoast must ensure that all hydrophones used in SFV measurements systems have undergone a full system, traceable laboratory calibration conforming to International Electrotechnical Commission (IEC) 60565, or an equivalent standard procedure from a factory or accredited source, at a date not to exceed 2 years before deployment, to guarantee each hydrophone receives accurate sound levels. Additional in situ calibration checks using a pistonphone must be performed before and after each hydrophone deployment. If the measurement system employs filters via hardware or software (e.g., high-pass, low-pass), which is not already accounted for by the calibration, the filter performance (i.e., the filter's frequency response) must be known, reported, and the data corrected for the filter's effect before analysis; x) SouthCoast Wind must be prepared with additional equipment (e.g., hydrophones, recording devices, hydrophone calibrators, cables, batteries), which exceeds the amount of equipment necessary to perform the measurements, such that technical issues can be mitigated before measurement; y) If any of the SFV measurements from any pile indicate that the distance to any isopleth of concern is greater than those modeled assuming 10-dB attenuation, before the next pile is installed, SouthCoast Wind must implement the following measures, as applicable: identify and propose for review and concurrence; additional, modified, and/or alternative noise attenuation measures or operational changes that present a reasonable likelihood of reducing sound levels to the modeled distances; provide a written explanation to NMFS Office of Protected Resources supporting that determination, and request concurrence to proceed; and, following NMFS Office of Protected Resources' concurrence, deploy those additional measures on any subsequent piles that are installed (e.g., if threshold distances are exceeded on pile 1, then additional measures must be deployed before installing pile 2); z) If SFV measurements indicate that ranges to isopleths corresponding to the Level A harassment and Level B harassment thresholds are less than the ranges predicted by modeling (assuming 10-dB attenuation) for three consecutive monopiles or four consecutive pin piles, SouthCoast Wind may submit a request to NMFS Office of Protected Resources for a modification of the mitigation zones for non-North Atlantic right whale species. Mitigation zones for North Atlantic right whales cannot be decreased; aa) SouthCoast must measure background noise (i.e., noise absent pile driving) for 30 minutes before and after each pile installation; bb) SouthCoast must conduct SFV measurements during turbine operations to estimate turbine operation source levels, in accordance with a NMFS-approved WTG Operational SFV Plan; and cc) SouthCoast Wind must submit SFV Plans for T-SFV and A-SFV for foundation installation to NMFS Office of Protected Resources for review and approval at least 180 days prior to planned start of foundation installation activities and abide by the Plan if approved. Pile driving may not occur until NMFS provides SouthCoast concurrence that implementation of the Foundation Installation SFV Plan meets the requirements in the LOA.		
4	C	UXO/MEC detonation	The following requirements apply to Unexploded Ordnances and Munitions and Explosives of Concern (UXO/MEC) detonation: a) Upon encountering a UXO/MEC, SouthCoast Wind can only resort to high-order removal (i.e., detonation) if all other means of removal are impracticable (i.e., As Low As Reasonably Practicable (ALARP) risk mitigation procedure)) and this determination must be documented and submitted to NMFS; b) UXO/MEC detonations must not occur December 1 through April 30;	Marine Mammals	NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			c) UXO/MEC detonations must only occur during daylight hours (1 hour after civil sunrise through 1.5 hours prior to civil sunset; d) No more than one detonation can occur within a 24-hour period. No more than 10 detonations may occur throughout the effective period of the LOA; e) SouthCoast Wind must deploy, at minimum, a double-bubble curtain during all UXO/MEC detonations and comply with the following requirements related to noise abatement; i. The bubble curtain(s) must distribute air bubbles using an air flow rate of at least 0.5 m3 /(min*m). The bubble curtain(s) must surround 100 percent of the UXO/MEC detonation perimeter throughout the full depth of the water column. In the unforeseen event of a single compressor malfunction, the offshore personnel operating the bubble curtain(s) must make adjustments to the air supply and operating pressure such that the maximum possible noise attenuation performance of the bubble curtain(s) is achieved; ii. The lowest bubble ring must be in contact with the seafloor for the full circumference of the ring, and the weights attached to the bottom ring must ensure 100-percent seafloor contact; iii. No parts of the ring or other objects may prevent full seafloor contact; iv. Construction contractors must train personnel in the proper balancing of airflow to the ring. Construction contractors must submit an inspection/performance report for approval by SouthCoast Wind within 72 hours following the performance test. SouthCoast Wind must then submit that report to NMFS Office of Protected Resources; v. Corrections to the bubble ring(s) to meet the performance standards in this paragraph (5) must occur prior to UXO/MEC detonations. If SouthCoast Wind uses a noise mitigation device in addition to the bubble curtain, SouthCoast Wind must maintain similar quality control measures as described in this paragraph (5); and vi. (vi) SouthCoast Wind must inspect and carry out maintenance on the noise attenuation system prior to every UXO/MEC detonation and prepare and submit a Noise Attenuation System (NAS) inspection/performance report as soon as it is available to NMFS Office of Protected Resources. f) SouthCoast Wind must conduct SFV during all UXO/MEC detonations at a minimum of three locations (with hydrophones at two water depths at each location) along a transect from each detonation site in a direction toward deeper water, in accordance with the following requirements: i. SouthCoast Wind must empirically determine source levels (peak and cumulative sound exposure level), the ranges to the Level A harassment and Level B harassment threshold isopleths and the transmission loss coefficient(s). SouthCoast Wind may estimate ranges to the Level A harassment and Level B harassment isopleths by extrapolating from in situ measurements conducted at several distances from the detonation location; ii. The SFV measurement systems must have a sensitivity for the expected sound levels from detonations received at the nominal ranges throughout the detonation. The dynamic range of the SFV measurement systems must be sufficient such that at each location, the signals avoid poor signal-to noise ratios for low amplitude signals and the signals avoid clipping, nonlinearity, and saturation for high amplitude signals; iii. All hydrophones used for SFV measurements are required to have undergone a full system, traceable laboratory calibration conforming to International Electrotechnical Commission (IEC) 60565, or an equivalent standard procedure, from a factory or accredited source to ensure the hydrophone receives accurate sound levels, at a date not to exceed 2 years before deployment. Additional in-situ calibration checks using a pistonphone are required to be performed before and after each hydrophone deployment. If the measurement system employs filters via hardware or software (e.g., high-pass, low-pass, etc.), which is not already accounted for by the calibration, the filter performance (i.e., the filter's frequency response) must be known, reported, and the data corrected before analysis; iv. SouthCoast Wind must be prepared with additional equipment (e.g., hydrophones, recording devices, hydrophone calibrators, cables, batteries, etc.), which exceeds the amount of equipment necessary to perform the measurements, such that technical issues can be mitigated before measurement; v. SouthCoast Wind must submit SFV reports within 72 hours after each UXO/MEC detonation; vi. If SFV measurements collected for a UXO/MEC detonation event indicate ranges to the isopleths, corresponding to Level A harassment and Level B harassment thresholds, are greater than the ranges predicted by modeling (assuming 10 dB attenuation), SouthCoast Wind must implement additional noise mitigation measures prior to the		

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			next UXO/MEC detonation. SouthCoast Wind must provide written notification to NMFS Office of Protected Resources of the changes planned for the next detonation within 24 hours prior to implementation. Subsequent UXO/MEC detonation activities must not occur until NMFS and SouthCoast Wind can evaluate the situation and ensure future detonations will not exceed noise levels modeled assuming 10-dB attenuation; and vii. SouthCoast Wind must optimize the noise attenuation systems (e.g., ensure hose maintenance, pressure testing) to, at least, meet noise levels modeled, assuming 10-dB attenuation. g) SouthCoast Wind must establish and implement clearance zones for UXO/MEC detonations using both visual and acoustic monitoring. UXO/MEC clearance zones are specific to the known charge weight size of the UXO/MEC to be detonated; if charge weight is unknown or uncertain then the clearance zone identified for the largest charge weight (i.e., E12) must be implemented; h) At least three on-duty PSOs must be stationed on each monitoring platform and monitoring for 60 minutes prior to, during, and 30 minutes after each UXO/MEC detonation. The number of platforms is contingent upon the size of the UXO/MEC detonation and must be sufficient such that PSOs are able to visually clear the entire clearance zone. Concurrently, at least one PAM operator must be actively monitoring for marine mammals with PAM 60 minutes before, during, and 30 minutes after detonation. SouthCoast must identify the number of platforms planned for each size class and describe all monitoring protocols in the UXO/MEC Detonation Marine Mammal Monitoring Plan; and i) All clearance zones must be confirmed to be acoustically free of marine mammals for 30 minutes prior to a detonation. If a marine mammal is observed entering or within the relevant clearance zone prior to the initiation of a detonation, detonation must be delayed and must not begin until either the marine mammal(s) has voluntarily left the specific clearance zones and have been visually and acoustically confirmed beyond that clearance zone, or, when specific time periods have elapsed with no further sightings or acoustic detections. The specific time periods are 30 minutes for all baleen whale species and sperm whales and 15 minutes for all other species.		
5	C	HRG Surveys	The following requirements apply to HRG surveys operating sub-bottom profilers (SBPs) (e.g., boomers, sparkers, and Compressed High Intensity Radiated Pulse (CHIRPS)) (hereinafter referred to as "acoustic sources"): a) SouthCoast Wind must establish and implement clearance and shutdown zones for HRG surveys using visual monitoring. These zones must be measured using the radial distance(s) from the acoustic source(s) currently in use; b) SouthCoast must utilize PSO(s), as described in Section 4(a). Visual monitoring must begin no less than 30 minutes prior to initiation of specified acoustic sources and must continue until 30 minutes after use of specified acoustic sources ceases. Any PSO on duty has the authority to delay the start of survey operations or shutdown operations if a marine mammal is detected within the applicable zones. When delay or shutdown is instructed by a PSO, the mitigative action must be taken and any dispute resolved only following deactivation; c) Prior to starting the survey and after receiving confirmation from the PSOs that the clearance zone is clear of any marine mammals, SouthCoast Wind is required to ramp-up acoustic sources to half power for 5 minutes prior to commencing full power, unless the equipment operates on a binary on/off switch (in which case rampup is not required). Any ramp-up of acoustic sources may only commence when visual clearance zones are fully visible (e.g., not obscured by darkness, rain, fog, etc.) and clear of marine mammals, as determined by the Lead PSO, for at least 30 minutes immediately prior to the initiation of survey activities using a specified acoustic source. Ramp-ups must be scheduled so as to minimize the time spent with the source activated; d) Prior to a ramp-up procedure starting, the acoustic source operator must notify the Lead PSO of the planned start of ramp-up. The notification time must not be less than 60 minutes prior to the planned ramp-up or activation in order to allow the PSO(s) time to monitor the clearance zone(s) for 30 minutes prior to the initiation of ramp-up or activation (pre-start clearance). During this 30-minute clearance period, the entire applicable clearance zones must be visible e) A PSO conducting clearance observations must be notified again immediately prior to reinitiating ramp-up procedures and the operator must receive confirmation from the PSO to proceed. f) If a marine mammal is observed within a clearance zone during the 30 minute clearance period, ramp-up or acoustic surveys may not begin until the animal(s) has been observed voluntarily exiting its respective clearance zone or until a specific time period has elapsed with no further sighting. The specific time periods are 30 minutes for all baleen whale species and sperm whales and 15 minutes for all other species;	Marine Mammals	NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			g) In any case when the clearance process has begun in conditions with good visibility, including via the use of night vision/reduced visibility monitoring equipment (infrared (IR)/thermal camera), and the Lead PSO has determined that the clearance zones are clear of marine mammals, survey operations may commence (i.e., no delay is required) despite periods of inclement weather and/or loss of daylight. Ramp-up may occur at times of poor visibility, including nighttime, if required visual monitoring has occurred with no detections of marine mammals in the 30 minutes prior to beginning ramp-up; h) Once the survey has commenced, SouthCoast Wind must shut down acoustic sources if a marine mammal enters a respective shutdown zone. In cases when the shutdown zones become obscured for brief periods (less than 30 minutes) due to inclement weather, survey operations would be allowed to continue (i.e., no shutdown is required) so long as no marine mammals have been detected. The shutdown requirement does not apply to small delphinids of the following genera: Delphinus, Stenella, Lagenorhynchus, and Tursiops. If there is uncertainty regarding the identification of a marine mammal species (i.e., whether the observed marine mammal belongs to one of the delphinid genera for which shutdown is waived), the PSOs must use their best professional judgment in making the decision to call for a shutdown. Shutdown is required if a delphinid that belongs to a genus other than those specified in this paragraph of this section is detected in the shutdown zone; i) If an acoustic source has been shut down due to the presence of a marine mammal, the use of an acoustic source may not commence or resume until the animal(s) has been confirmed to have left the Level B harassment zone or until a full 30 minutes for all baleen whale species and sperm whales and 15 minutes for all other species have elapsed with no further sighting. If an acoustic source is shut down for reasons other than mitigation (e.g., mechanical difficulty) for less than 30 minutes, it may be activated again without ramp-up only if PSOs have maintained constant observation and no additional detections of any marine mammal occurred within the respective shutdown zones. If an acoustic source is shut down for a period longer than 30 minutes, then all clearance and ramp-up procedures must be initiated; j) If multiple HRG vessels are operating concurrently, any observations of marine mammals must be communicated to PSOs on all nearby survey vessels; and k) Should an autonomous survey vehicle (ASV) be used during HRG surveys, the ASV must remain with 800 m (2,635 ft) of the primary vessel while conducting survey operations; two PSOs must be stationed on the mother vessel at the best vantage points to monitor the clearance and shutdown zones around the ASV; at least one PSO must monitor the output of a thermal high-definition camera installed on the mother vessel to monitor the field-of-view around the ASV using a hand-held tablet, and during periods of reduced visibility (e.g., darkness, rain, or fog), PSOs must use night-vision goggles with thermal clip-ons and a hand-held spotlight to monitor the clearance and shutdown zones around the ASV.		
6	C, O&M	Fisheries monitoring surveys	The following measures apply during fisheries monitoring surveys and must be implemented by SouthCoast Wind: a) Marine mammal monitoring must be conducted within 1 nm (1.85 km) from the planned survey location by the trained captain and/or a member of the scientific crew for 15 minutes prior to deploying gear, throughout gear deployment and use, and for 15 minutes after haul back; b) All captains and crew conducting fishery surveys must be trained in marine mammal detection and identification; c) Gear must not be deployed if there is a risk of interaction with marine mammals. Gear must not be deployed until a minimum of 15 consecutive minutes have elapsed during which no marine mammal sightings within 1 nm (1,852 m) of the sampling station have occurred; d) If marine mammals are sighted within 1 nm of the planned location (i.e., station) within the 15 minutes prior to gear deployment, then SouthCoast Wind must move the vessel away from the marine mammal to a different section of the sampling area. If, after moving on, marine mammals are still visible from the vessel, SouthCoast Wind must move again to an area visibly clear of marine mammals or skip the station; e) If a marine mammal is at risk of interacting with deployed gear or set, all gear must be immediately removed from the water. If marine mammals are sighted before the gear is fully removed from the water, the vessel must slow its speed and maneuver the vessel away from the animals to minimize potential interactions with the observed animal; f) Survey gear must be deployed as soon as possible once the vessel arrives on station and after fulfilling the requirements in (f)(1) and (f)(3);	Marine Mammals	NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			g) SouthCoast Wind must maintain visual marine mammal monitoring effort during the entire period of time that gear is in the water (i.e., throughout gear deployment, fishing, and retrieval). If marine mammals are sighted before the gear is fully removed from the water, SouthCoast Wind will take the most appropriate action to avoid marine mammal interaction; h) All fisheries monitoring gear must be fully cleaned and repaired (if damaged) before each use/deployment; i) SouthCoast Wind's fixed gear must comply with the Atlantic Large Whale Take Reduction Plan regulations at 50 CFR 229.32 during fisheries monitoring surveys; j) Trawl tows must be limited to a maximum of 20 minute trawl-time and trawl tows must not exceed at a speed of 3.0 knots (3.5 mph); k) All gear must be emptied as close to the deck/sorting area and as quickly as possible after retrieval; l) During trawl surveys, vessel or scientific crew must open the cod end of the trawl net close to the deck in order to avoid injury to animals that may be caught in the gear; m) All fishery survey-related lines must include the breaking strength of all lines being less than 1,700 pounds (lbs; 771 kilograms (kg)). This may be accomplished by using whole buoy line that has a breaking strength of 1,700 lbs (771 kg); or buoy line with weak inserts that result in line having an overall breaking strength of 1,700 lbs (771 kg); n) During any survey that uses vertical lines, buoy lines must be weighted and must not float at the surface of the water. All groundlines must be composed entirely of sinking lines. Buoy lines must utilize weak links. Weak links must break cleanly leaving behind the bitter end of the line. The bitter end of the line must be free of any knots when the weak link breaks. Splices are not considered to be knots. The attachment of buoys, toggles, or other floatation devices to groundlines is prohibited; o) All in-water survey gear, including buoys, must be properly labeled with the scientific permit number or identification as SouthCoast Wind's research gear. All labels and markings on the gear, buoys, and buoy lines must also be compliant with the applicable regulations, and all buoy markings must comply with instructions received by the NOAA Greater Atlantic Regional Fisheries Office Protected Resources Division; p) All survey gear must be removed from the water whenever not in active survey use (i.e., no wet storage); q) All reasonable efforts that do not compromise human safety must be undertaken to recover gear; r) Any lost gear associated with the fishery surveys must be reported to the NOAA Greater Atlantic Regional Fisheries Office Protected Resources Division within 24 hours.		
7	C, O&M, D	PSO and PAM operator qualifications	SouthCoast Wind must implement the following measures applicable to PSOs and PAM operators: a) SouthCoast Wind must use NMFS-approved PSOs and PAM operators that are employed by a third-party observer provider. PSOs and PAM operators must have no tasks other than to conduct observational effort, collect data, and communicate with and instruct relevant personnel regarding the presence of marine mammals and mitigation requirements; b) All PSOs and PAM operators must have successfully attained a bachelor's degree from an accredited college or university with a major in one of the natural sciences. The educational requirements may be waived if the PSO or PAM operator has acquired the relevant experience and skills for visually and/or acoustically detecting marine mammals in a range of environmental conditions (e.g., sea state, visibility) within zone sizes equivalent to the clearance and shutdown zones required by these regulations. Requests for such a waiver must be submitted to NMFS Office of Protected Resources prior to or when SouthCoast Wind requests PSO and PAM operator approvals and must include written justification describing alternative experience. Alternate experience that may be considered includes, but is not limited to, conducting academic, commercial, or government-sponsored marine mammal visual and/or acoustic surveys or previous work experience as a PSO/PAM operator. All PSO's and PAM operators should demonstrate good standing and consistently good performance of all assigned duties; c) PSOs must have visual acuity in both eyes (with correction of vision being permissible) sufficient enough to discern moving targets on the water's surface with the ability to estimate the target size and distance (binocular use is allowable); ability to conduct field observations and collect data according to the assigned protocols, writing skills sufficient to document observations and the ability to communicate orally by radio or in-person with project personnel to provide real-time information on marine mammals observed in the area; d) All PSOs must be trained in northwestern Atlantic Ocean marine mammal identification and behaviors and must be able to conduct field observations and collect data according to assigned protocols. Additionally, PSOs must have the ability to work	Marine Mammals	NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			with all required and relevant software and equipment necessary during observations (as described in paragraphs (b)(2) and (b)(3) of this section); e) All PSOs and PAM operators must have successfully completed a PSO, PAM, or refresher training course within the last 5 years and obtained a certificate of course completion that must be submitted to NMFS. This requirement is waived for any PSOs and PAM operators that completed a relevant training course more than five years prior to seeking approval but have been working consistently as a PSO or PAM operator within the past five years; f) At least one on-duty PSO and PAM operator, where applicable, per platform must be designated as a Lead during each of the specified activities; g) PSOs are responsible for obtaining NMFS' approval. NMFS may approve PSOs as conditional or unconditional. An unconditionally approved PSO is one who has completed training within the last 5 years and attained the experience (i.e., demonstrate experience with monitoring for marine mammals at clearance and shutdown zone sizes similar to those produced during the respective activity) or for PSOs who completed training more than five years previously and have worked in the specified role consistently for at least the past 5 years. A conditionally approved PSO may be one who has completed training in the last 5 years but has not yet attained the requisite field experience. To qualify as a Lead PSO, the person must be unconditionally approved and demonstrate that they have a minimum of 90 days of at-sea experience in the specific role, with the conclusion of the most recent relevant experience not more than 18 months previous to deployment and must also have experience specifically monitoring baleen whale species; h) PSOs for HRG surveys may be unconditionally or conditionally approved. A conditionally approved PSO for HRG surveys must be paired with an unconditionally approved PSO; i) PSOs and PAM operators for foundation installation and UXO detonation must be unconditionally approved; j) For all prospective project PSOs and PAM operators, SouthCoast Wind must submit resumes, NMFS approval letters, and certificates of completion of NMFS-approved PSO and/or PAM training/courses to NMFS' Office of Protected Resources for review and confirmation of their approval for specific roles at least 90 days prior to commencement of the activities requiring PSOs/PAM operators, or at least 30 days prior to when new PSOs/PAM operators are required after activities have commenced. Resumes must include information related to relevant education, experience, and training, including role, deployment dates and duration (i.e., number of days as a PSO or PAM operator per project), location and description of each prior PSO or PAM operator experience (i.e., zone sizes monitored, how monitoring supported mitigation, PAM system/software utilized); k) For prospective PSOs and PAM operators not previously approved by NMFS or for PSOs and PAM operators whose approval is not current (i.e., approval date is more than 5 years prior to the start of monitoring duties), SouthCoast Wind must submit the list of pre-approved PSOs and PAM operators for qualification verification at least 60 days prior to PSO and PAM operator use. Resumes must include information detailed in 217.335(a)(9). Resumes must be accompanied by certificate of completion of a NMFS-approved PSO and/or PAM training/course l) PAM operators are responsible for obtaining NMFS' approval. To be approved as a PAM operator, the person must meet the following qualifications: the PAM operator must have completed a PAM Operator training course, and demonstrate prior experience using PAM software, equipment, and real-time acoustic detection systems. They must demonstrate that they have prior experience independently analyzing archived and/or real-time PAM data to identify and classify baleen whale and other marine mammal vocalizations by species, including North Atlantic right whale and humpback whale vocalizations, and experience with deconflicting multiple species' vocalizations that are similar and/or received concurrently. PAM operators must be independent observers (i.e., not construction personnel), trained to use relevant project-specific PAM software and equipment, and must also be able to test software and hardware functionality prior to beginning real-time monitoring. The PAM operator must be able to identify and classify marine mammal acoustic detections by species in real-time (prioritizing North Atlantic right whales and noting other marine mammal vocalizations, when detected). At a minimum, for each acoustic detection, the PAM operator must be able to categorically determine whether a North Atlantic right whale is detected, possibly detected, or not detected, and notify the Lead PSO of any confirmed or possible detections, including baleen whale detections that cannot be identified to species. If the PAM software is capable of localization of sounds or deriving bearings and distance, the PAM operators must demonstrate experience using this technique; m) PSOs may work as PAM operators and vice versa if NMFS approves each individual for both roles; however, they may only perform one role at any one time and must not exceed work time restrictions, which must be tallied cumulatively; and		

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			n) All PSOs and PAM operators must complete a Permits and Environmental Compliance Plan training that must be held by the Project compliance representative(s) prior to the start of in-water project activities and whenever new PSOs and PAM operators join the marine mammal monitoring team. PSOs and PAM operators must also complete training and orientation with the construction operation to provide for personal safety.		
8	C, O&M, D	General PSO and PAM operator requirements	The following measures apply to PSOs and PAM operators and must be implemented by SouthCoast Wind: a) All PSOs must be located at the best vantage point(s) on any platform, as determined by the Lead PSO, in order to collectively obtain 360-degree visual coverage of the entire clearance and shutdown zones around the activity area and as much of the Level B harassment zone as possible. PAM operators may be located on a vessel or remotely on-shore but must have a computer station equipped with a data collection software system and acoustic data analysis software available wherever they are stationed, and data or data products must be streamed in real-time or in near real-time to allow PAM operators to provide assistance to on-duty PSOs in determining if mitigation is required (i.e., delay or shutdown); b) PSOs must use high magnification (25x) binoculars, standard handheld (7x) binoculars, and the naked eye to search continuously for marine mammals during visual monitoring. During foundation installation, at least three PSOs on each dedicated PSO vessel must be equipped with functional Big Eye binoculars (e.g., 25 x 150; 2.7 view angle; individual ocular focus; height control). These must be pedestal mounted on the deck at the best vantage point that provides for optimal sea surface observation and PSO safety. PAM operators must use a NMFS-approved PAM system to conduct acoustic monitoring; c) During periods of low visibility (e.g., darkness, rain, fog, poor weather conditions), PSOs must use alternative technology (e.g., infrared or thermal cameras) to monitor the mitigation zones; d) PSOs and PAM operators must not exceed 4 consecutive watch hours on duty at any time, must have a 2-hour (minimum) break between watches, and must not exceed a combined watch schedule of more than 12 hours in a 24-hour period; and e) SouthCoast Wind must ensure that PSOs conduct, as rotation schedules allow, observations for comparison of sighting rates and behavior with and without use of the specified acoustic sources. Off-effort PSO monitoring must be reflected in the PSO monitoring reports;	Marine Mammals	NMFS
9	C, O&M, D	Reporting	SouthCoast Wind must comply with the following reporting measures: a) Prior to initiation of project activities, SouthCoast Wind must demonstrate in a report submitted to NMFS Office of Protected Resources (pr.itp.monitoringreports@noaa.gov) that all required training for SouthCoast Wind personnel, including the vessel crews, vessel captains, PSOs, and PAM operators has been completed; b) SouthCoast Wind must use a standardized reporting system. All data collected related to the Project must be recorded using industry-standard software that is installed on field laptops and/or tablets. Unless stated otherwise, all reports must be submitted to NMFS Office of Protected Resources (PR.ITP.MonitoringReports@noaa.gov), dates must be in MM/DD/YYYY format, and location information must be provided in Decimal Degrees and with the coordinate system information (e.g., NAD83, WGS84); c) For all visual monitoring efforts and marine mammal sightings, the following information must be collected and reported to NMFS Office of Protected Resources: the date and time that monitored activity begins or ends; the construction activities occurring during each observation period; the watch status (i.e., sighting made by PSO on/off effort, opportunistic, crew, alternate vessel/platform); the PSO who sighted the animal; the time of sighting; the weather parameters (e.g., wind speed, percent cloud cover, visibility) and water conditions (e.g., Beaufort sea state, tide state, water depth); all marine mammal sightings, regardless of distance from the construction activity; species (or lowest possible taxonomic level possible); the pace of the animal(s); the estimated number of animals (minimum/maximum/high/low/best); the estimated number of animals by cohort (e.g., adults, yearlings, juveniles, calves, group composition, etc.); the description (i.e., as many distinguishing features as possible of each individual seen, including length, shape, color, pattern, scars or markings, shape and size of dorsal fin, shape of head, and blow characteristics); the description of any marine mammal behavioral observations (e.g., feeding or traveling), definitions of any behavioral categories used (e.g., travel means directed movement at moderate speed), and observed changes in behavior, including an assessment of behavioral responses thought to have resulted from the specific activity; the animal's closest distance (i.e., closest point of approach) and bearing from the pile being driven, UXO/MEC detonation site, or specified HRG equipment; estimated time entered or spent within the Level A harassment and/or Level B harassment zone(s); status of any noise attenuation device(s) at time of sighting (e.g., double-bubble curtain on); specific phase of activity (e.g., ramp-up of HRG equipment, HRG acoustic source on/off, soft-start for pile	Marine Mammals	NMFS

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			driving, active pile driving); the timing and description of any mitigation-related action implemented, or mitigation-related actions called for but not implemented, in response to the sighting (e.g., delay, shutdown, etc.); other human activity in the area; and other applicable information, as required in any LOA issued under section 5 herein; d) For all PAM deployments, the following information must be recorded and reported to NMFS: location of hydrophone (latitude and longitude; in Decimal Degrees) and site name; bottom depth and depth of recording unit (in meters); recorder (model & manufacturer) and platform type (i.e., bottom-mounted, electric glider, etc.), and instrument ID of the hydrophone and recording platform (if applicable); time zone for sound files and recorded date/times in data and metadata (in relation to Universal Coordinated Time (UTC); i.e., Eastern Standard Time (EST) time zone is UTC-5); duration of recordings (start/end dates and times; in International Organization for Standardization (ISO) 8601 format, yyyymm-ddTHH:MM:SS.sssZ); deployment/retrieval dates and times (in ISO 8601 format); recording schedule (must be continuous); hydrophone and recorder sensitivity (in dB re. 1 microPascal (µPa)); calibration curve for each recorder; bandwidth/sampling rate (in Hz); sample bit-rate of recordings; and, detection range of equipment for relevant frequency bands (in meters); i. For each detection, the following information the following information must be noted: species identification (if possible); call type, number of calls (if known) and number of species (if simultaneous calls detected); temporal aspects of vocalization (date, time, duration, etc.; date times in ISO 8601 format); confidence of detection (detected, or possibly detected); comparison with any concurrent visual sightings; location and/or directionality of call location (if determined) relative to acoustic recorder or construction activities; location of recorder and construction activities at time of call; name and version of detection or sound analysis software used, with protocol reference; duration of detection file and minimum and maximum frequencies viewed/monitored/used in detection (in Hz); and name of PAM operator(s) on duty. e) SouthCoast Wind must compile and submit weekly reports during foundation installation containing marine mammal monitoring and A-SFV data to NMFS Office of Protected Resources (pr.itp.monitoringreports@noaa.gov). Weekly reports are due on Wednesday for the previous week (Sunday – Saturday). In the reports, SouthCoast must provide the daily start and stop of all pile driving; the start and stop of associated observation periods by PSOs; details on the deployment of PSOs; a record of all detections of marine mammals (acoustic and visual); any mitigation actions (or if mitigation actions could not be taken, provide reasons why); and details on the noise attenuation system(s) used and its performance. The weekly report must also identify which turbines were installed, and when/if any become operational (a map must be provided). f) SouthCoast Wind must compile and submit monthly reports to NMFS Office of Protected Resources (pr.itp.monitoringreports@noaa.gov) during foundation installation that include a summary of all information in the weekly reports, including project activities carried out in the previous month, vessel transits (number, type of vessel, MMSI number, and route), number of piles installed, table(s) including all visual and acoustic detections of marine mammals, and any mitigative action taken. Monthly reports are due on the 15th of the month for the previous month. The monthly report must also identify which turbines were installed and when/if any became operational (a map must be provided). Full PAM detection data and metadata must also be submitted monthly on the 15th of every month for the previous month via the webform on the NMFS North Atlantic Right Whale Passive Acoustic Reporting System website at https://www.fisheries.noaa.gov/resource/document/passive-acoustic-reportingsystem-templates; g) SouthCoast Wind must submit a draft annual marine mammal monitoring report to NMFS (PR.ITP.monitoringreports@noaa.gov) no later than March 31, annually, which contains data for all specified activities. The draft and final reports must detail the following: the total number of marine mammals of each species/stock detected and how many were within the designated Level A harassment and Level B harassment zone(s) and a comparison with the number of authorized takes of marine mammals for the associated activity type; marine mammal detections and behavioral observations before, during, and after each activity; what mitigation measures were implemented (i.e., number of shutdowns or clearance zone delays, etc.) or, if no mitigative actions was taken, why; operational details (i.e., days and duration of impact and vibratory pile driving, number of UXO/MEC detonations, days and amount of HRG survey effort, etc.); PAM systems used; the results, effectiveness, and which noise attenuation systems were used during relevant activities (i.e., foundation pile driving); summarized information related to situational reporting; and any other important information relevant to the Project, including additional information that may be identified through the adaptive management process. The final annual report must be prepared and submitted within 30 calendar days following the receipt of any comments from NMFS on the draft report;		

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			h) In addition to the 48-hour interim reports, SouthCoast Wind must submit a draft annual SFV report to NMFS (PR.ITP.monitoringreports@noaa.gov) no later than 90 days after SFV is completed for the year. The final annual SFV report must be prepared and submitted within 30 calendar days (or longer upon approval by SouthCoast Wind must submit its draft 5-year report to NMFS Office of Protected Resources (PR.ITP.monitoringreports@noaa.gov) on all visual and acoustic monitoring conducted within 90 calendar days of the completion of activities occurring under the LOA. A 5-year report must be prepared and submitted within 60 calendar days (or longer upon approval by NMFS) following receipt of any NMFS Office of Protected Resources comments on the draft report; i) SouthCoast Wind must provide the initial results of the T-SFV measurements to NMFS Office of Protected Resources (PR.ITP.monitoringreports@noaa.gov) in an interim report after each foundation installation event as soon as they are available, but no later than 48 hours after each completion of T-SFV for a given foundation. The report must include, at minimum: pile identifier name, location of the pile and each hydrophone array in latitude/longitude; depths of each hydrophone; hammer energies/schedule used during pile driving including the total number of strikes and the maximum hammer energy; the model-estimated acoustic ranges (R95%) to compare with the real-world sound field measurements; peak sound pressure level (SPLpk), root-mean-square sound pressure level that contains 90 percent of the acoustic energy (SPLrms), and sound exposure level (SEL, in single strike for impact pile driving, SELss and SEL over 1-second interval for vibratory pile driving) for each hydrophone, including at least the maximum, arithmetic mean, minimum, median (L50) and L5 (95 percent exceedance) statistics for each metric; estimated ranges to marine mammal Level A harassment and Level B harassment acoustic isopleths estimated using SFV data, calculated using the maximum-over-depth L5 (95 percent exceedance level, maximum of both hydrophones) of the associated sound metric; comparison of modeled results assuming 10-dB attenuation against the measured marine mammal Level A harassment and Level B harassment acoustic isopleths; estimated transmission loss coefficients; one-third-octave band SEL spectra for impact and vibratory pile driving for each hydrophone; if filtering is applied, full filter characteristics must be reported; and hydrophone specifications including the type, model, and sensitivity. SouthCoast Wind must also report any immediate observations which are suspected to have a significant impact on the results including but not limited to: observed noise mitigation system issues, obstructions along the measurement transect, technical issues with hydrophones or recording devices, interfering noise sources (e.g., vessel traffic). If any in-situ calibration checks for hydrophones reveal a calibration drift greater than 0.75 dB, that pistonphone calibration checks are inconclusive, or that calibration checks are otherwise not effectively performed, SouthCoast Wind must indicate full details of the calibration procedure and results, and any associated issues in the 48-hour interim reports; j) All A-SFV results must be included in the weekly reports. Any indications that distances to the identified Level A harassment and Level B harassment threshold isopleths for marine mammals were exceeded must be addressed by SouthCoast Wind in the reports, including an explanation of factors that contributed to the exceedance and corrective actions that were taken to avoid exceedance on subsequent piles, if applicable; k) SouthCoast Wind must provide NMFS Office of Protected Resources with notification of planned UXO/MEC detonation as soon as possible but at least 48 hours prior to the planned detonation unless this 48-hour notification requirement would create delays to the detonation that would result in imminent risk of human life or safety. This notification must include the coordinates of the planned detonation, the estimated charge size, and any other information available on the characteristics of the UXO/MEC; l) SouthCoast Wind must submit SFV results for a UXO/MEC detonation in a report submitted to NMFS Office of Protected Resources (PR.ITP.MonitoringReports@noaa.gov) prior to detonating a subsequent UXO/MEC, or within the relevant weekly report, whichever comes first; m) SouthCoast must submit bubble curtain performance reports for foundation installations within 48 hours of each bubble curtain deployment; n) The final results of all SFV measurements from each foundation installation and UXO/MEC detonation must be submitted as soon as possible, but no later than 90 days following completion of all annual SFV measurements. The final reports must include all details included in the interim reports and descriptions of any notable occurrences, explanations for results that were not anticipated, and mitigative actions taken during foundation installation to reduce noise levels (e.g., cleaning and redeploying bubble curtain hose). The final report must also include at least the maximum, mean, minimum, median (L50) and L5 (95 percent exceedance) statistics for each metric; the SEL and SPL power spectral density and/or one-third octave band levels (usually calculated as decidecade band levels) at the receiver locations should be reported; range of transmission		

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			loss coefficients; the local environmental conditions, such as wind speed, transmission loss data collected on-site (or the sound velocity profile); baseline pre- and postactivity ambient sound levels (broadband and/or within frequencies of concern); a description of depth and sediment type, as documented in the Construction and Operation Plan (COP), at the acoustic buoy and foundation installation and UXO/MEC detonation locations; the measured ranges to the Level A harassment and Level B harassment threshold isopleths; hammer energies required for pile installation and the number of strikes per pile; the hydrophone equipment and methods (i.e., recording device, bandwidth/sampling rate; distance from the pile where recordings were made; the depth of recording device(s)); a description of the SFV measurement hardware and software, including software version used, calibration data, bandwidth capability and sensitivity of hydrophone(s), any filters used in hardware or software, any limitations with the equipment, and other relevant information; the spatial configuration of the noise attenuation device(s) relative to the pile; a description of the noise abatement system and operational parameters (e.g., bubble flow rate, distance deployed from the pile, etc.), and any action taken to adjust the noise abatement system. A discussion which includes any observations that are suspected to have had a significant influence on the results including, but not limited to: observed noise mitigation system issues, obstructions along the measurement transect, technical issues with hydrophones or recording devices, deviation of propagation environment from that assumed for acoustic modeling, vessel noise interference; o) If at any time during the project SouthCoast Wind becomes aware of any issue or issues which may (to any reasonable subject-matter expert, including the persons performing the measurements and analysis) call into question the validity of any measured ranges to Level A harassment or Level B harassment threshold isopleths to a significant degree, which were previously transmitted or communicated to NMFS Office of Protected Resources, SouthCoast Wind must inform NMFS Office of Protected Resources within 1 business day of becoming aware of this issue or before the next pile is driven, whichever comes first. p) If a North Atlantic right whale is acoustically detected at any time by a project-related PAM system, SouthCoast Wind must ensure the detection is reported as soon as possible to NMFS, but no longer than 24 hours after the detection via the 24-hour North Atlantic right whale Detection Template (https://www.fisheries.noaa.gov/resource/document/passive-acoustic-reportingsystem-templates). Calling the hotline is not necessary when reporting PAM detections via the template; q) Full detection data, metadata, and location of recorders (or GPS tracks, if applicable) from all real-time hydrophones used for monitoring during foundation installations and UXO/MEC detonations must be submitted within 90 calendar days following completion of activities requiring PAM for mitigation via the International Organization for Standardization (ISO) standard metadata forms available on the NMFS Passive Acoustic Reporting System website (https://www.fisheries.noaa.gov/resource/document/passive-acousticreportingsystem-templates). Submit the completed data templates to nmfs.nec.pacmdata@noaa.gov. The full acoustic recordings from real-time systems must also be sent to the National Centers for Environmental Information (NCEI) for archiving within 90 days following completion of activities requiring PAM for mitigation. Submission details can be found at: https://www.ncei.noaa.gov/products/passive-acoustic-data; r) SouthCoast Wind must submit situational reports if specific circumstances occur, including but not limited to the following: i. All instances wherein an exemption to any of the requirements in the regulations and/or this LOA is taken must be reported to the NMFS Office of Protected Resources within 24 hours; ii. If a North Atlantic right whale is observed at any time by PSOs or project personnel, SouthCoast Wind must ensure the sighting is immediately (if not feasible, as soon as possible and no longer than 24 hours after the sighting) reported to NMFS, the U.S. Coast Guard, and the Right Whale Sightings Advisory System (RWSAS). If in the Northeast Region (Maine to Virginia/North Carolina border) call (866-755-6622). If in the Southeast Region (North Carolina to Florida) call (877-WHALE-HELP or 877-942- 5343). If circumstances arise where calling NMFS is not possible, reports must be made to the U.S. Coast Guard via channel 16 or through the WhaleAlert app (http://www.whalealert.org/). The sighting report must include the time, date, and location of the sighting, number of whales, animal description/certainty of sighting (provide photos/video if taken), evidence of previous or current entanglement, Lease Area/project name, PSO/personnel name, PSO provider company (if applicable), and reporter's contact information; iii. If a North Atlantic right whale is observed at any time by PSOs or project personnel, SouthCoast Wind must submit a summary report to NMFS Greater Atlantic Regional Fisheries (GARFO; nmfs.gar.incidentaltake@noaa.gov), NMFS		

#	Proposed Project Phase [a]	Mitigation & Monitoring Measures	Description	Resource Area Mitigated	Anticipated Enforcing Agency
			Office of Protected Resources (PR.ITP.MonitoringReports@noaa.gov) and NMFS Northeast Fisheries Science Center (NEFSC; ne.rw.survey@noaa.gov) within 24 hours with the above information and the vessel/platform from which the sighting was made, activity the vessel/platform was engaged in at time of sighting, project construction and/or survey activity at the time of the sighting (e.g., pile driving, cable installation, HRG survey), distance from vessel/platform to sighting at time of detection, and any mitigation actions taken in response to the sighting; iv. In the event that personnel involved in the Project discover a stranded, entangled, injured, or dead marine mammal, SouthCoast Wind must immediately report the observation to NMFS. If in the Greater Atlantic Region (Maine to Virginia) call the NMFS Greater Atlantic Stranding Hotline (866-755-6622); if in the Southeast Region (North Carolina to Florida), call the NMFS Southeast Stranding Hotline (877-942-5343). Separately, SouthCoast Wind must report the incident to NMFS Office of Protected Resources (PR.ITP.MonitoringReports@noaa.gov); if in the Greater Atlantic region (Maine to Virginia), to NMFS Greater Atlantic Regional Fisheries Office (GARFO; nmfs.gar.incidental-take@noaa.gov, nmfs.gar.stranding@noaa.gov); if in the Southeast region (North Carolina to Florida), to NMFS Southeast Regional Office (SERO; secmammalreports@noaa.gov); and to the U.S. Coast Guard, as soon as feasible but within 24-hours. The report (via phone or email) must include contact (name, phone number, etc.), the time, date, and location of the first discovery (and updated location information if known and applicable); species identification (if known) or description of the animal(s) involved; condition of the animal(s) (including carcass condition if the animal is dead); observed behaviors of the animal(s), if alive; if available, photographs or video footage of the animal(s); and general circumstances under which the animal was discovered; and v. In the event of a vessel strike of a marine mammal by any vessel associated with the Project or if project activities cause a non-auditory injury or death of a marine mammal, SouthCoast Wind must immediately report the incident to NMFS. If in the Greater Atlantic Region (Maine to Virginia) call the NMFS Greater Atlantic Stranding Hotline (866-755- 6622) and if in the Southeast Region (North Carolina to Florida) call the NMFS Southeast Stranding Hotline (877-942-5343). Separately, SouthCoast Wind must immediately report the incident to NMFS Office of Protected Resources (PR.ITP.MonitoringReports@noaa.gov) and, if in the Greater Atlantic region (Maine to Virginia), NMFS GARFO (nmfs.gar.incidental-take@noaa.gov, nmfs.gar.stranding@noaa.gov) or, if in the Southeast region (North Carolina to Florida), NMFS SERO (secmammalreports@noaa.gov). The report must include the time, date, and location of the incident; species identification (if known) or description of the animal(s) involved; vessel size and motor configuration (inboard, outboard, jet propulsion); vessel's speed leading up to and during the incident; vessel's course/heading and what operations were being conducted (if applicable); status of all sound sources in use; description of avoidance measures/requirements that were in place at the time of the strike and what additional measures were taken, if any, to avoid strike; environmental conditions (e.g., wind speed and direction, Beaufort sea state, cloud cover, visibility) immediately preceding the strike; estimated size and length of animal that was struck; description of the behavior of the marine mammal immediately preceding and following the strike; if available, description of the presence and behavior of any other marine mammals immediately preceding the strike; estimated fate of the animal (e.g., dead, injured but alive, injured and moving, blood or tissue observed in the water, status unknown, disappeared); and to the extent practicable, photographs or video footage of the animal(s). SouthCoast Wind must immediately cease all on-water activities until the NMFS Office of Protected Resources is able to review the circumstances of the incident and determine what, if any, additional measures are appropriate to ensure compliance with the terms of the LOA. NMFS Office of Protected Resources may impose additional measures to minimize the likelihood of further prohibited take and ensure MMPA compliance. SouthCoast Wind may not resume their activities until notified by NMFS Office of Protected Resources; and s) Any lost gear associated with the fishery surveys must be reported to the NOAA Greater Atlantic Regional Fisheries Office Protected Resources Division (nmfs.gar.incidentaltake@noaa.gov) as soon as possible or within 24 hours of the documented time of missing or lost gear. This report must include information on any markings on the gear and any efforts undertaken or planned to recover the gear.

Attachment G-1: SouthCoast Wind Request for Incidental Take Regulations Mitigation Measures

This attachment contains the mitigation measures proposed by SouthCoast Wind in its Request for Incidental Take Regulations application. BOEM anticipates that BOEM, BSEE, and NMFS would be the enforcing agencies for these measures.

Attachment G-2: SouthCoast Wind Draft Post-Construction Avian and Bat Monitoring Framework

11 Mitigation Measures

The monitoring and mitigation methods described below are intended to reduce or eliminate exposure of marine mammals to underwater sound levels that could constitute "take" under the MMPA. Many of the monitoring and mitigation methods are applicable across all Project activities while others will be specific to the following activities:

- WTG and OSP foundation installation using impact pile driving,
- WTG and OSP foundation installation using vibratory pile driving,
- High resolution geophysical (HRG) and remotely operated vehicle (ROV) surveys, and
- UXO detonation.

11.1 Standard Mitigation and Monitoring Requirements for all Project Activities

11.1.1 Protected Species Observer (PSO) and Acoustic Protected Species Observer (APSO) Experience and Responsibilities

11.1.1.1 Observer Qualifications and Training

- All PSOs and APSOs will have met NMFS and BOEM training and experience requirements (including a NMFS-approved PSO training course).
- PSOs and APSOs will be employed by a third-party observer provider.
- Briefings between construction supervisors and crews and the PSO/APSO team will be held prior to the start of all Project activities as well as when new personnel join the vessel(s).
- The PSO team and the APSO team will each have a lead observer (Lead PSO and Lead APSO) who will be unconditionally approved by NMFS and have a minimum of 90 days at-sea experience in a northwestern Atlantic Ocean environment performing the visual (Lead PSO) or acoustic role (Lead APSO), with the conclusion of the most recent relevant experience no more than 18 months previous.
- APSOs responsible for determining if an acoustic detection originated from a NARW will be trained in identification of mysticete vocalizations.

11.1.1.2 *Responsibilities and Authorities of PSOs and APSOs*

- PSOs will not have tasks other than to conduct observational effort, collect data, and communicate with and instruct relevant vessel crew with regard to the presence of marine mammals and mitigation requirements.
- Lead PSOs carry the same duties as PSOs and also manage the activities associated with the PSO team, PAM team, and SFV team.
- Any PSO or APSO on duty will have authority to delay the start of operations or to call for a shutdown based on their observations or acoustic detections.
- Lead APSOs will be able to troubleshoot the acoustic equipment and assist in making final decisions regarding species identifications, localization, and other acoustic monitoring details that will be relayed to the Lead PSO.
- A clear line and method of communication between the PSOs and APSOs will be established and maintained to ensure mitigation measures are conveyed without delay.

11.1.2 Visual Monitoring

- PSOs and APSOs will be on watch for a maximum of four consecutive hours followed by a break of at least two hours between watches and will conduct a maximum of 12 hours of observation per 24-hour period.
- Each PSO and APSO will be provided with one 8-hour break per 24-hour period to sleep.
- Observations will be conducted (or electronic monitoring equipment installed) from the best safe vantage point(s) on the vessel or base of operations to ensure visibility of the shutdown zones.
- SouthCoast Wind is exploring opportunities to use currently available technologies to conduct monitoring using PSOs and APSOs who may be stationed in locations other than offshore vessels (e.g., onshore); however, this does not exempt onsite PSO requirements

described throughout section 11 (e.g., PSOs onboard the pile driving vessel, detonation vessel, or HRG survey vessel)
    - Onshore monitoring may include the use of imagery or data transmitted in real time (or near real time) from sensors located offshore. For example, EO, IR, or PAM sensors may be located on a variety of potential platforms.
- When conducting observations during Project activities, PSOs will scan systematically with the unaided eye, high-magnification (25 x 150 mm) binoculars, and/or standard handheld (7 x 50 mm) binoculars or other electronic methods to search continuously for marine mammals during all observational periods.
- When monitoring at night, or in low visibility conditions, PSOs will monitor for marine mammals and other protected species using night-vision devices with thermal clip-ons, a hand-held spotlight, and/or a mounted thermal camera system or other electronic methods.
- PSOs will watch for and record all marine mammal sightings regardless of the distance from the observer and/or sound source.
- Distances to observed animals will be estimated with range finders, reticle binoculars, clinometers when possible, or other electronic methods and based on the best estimate of the PSO when necessary.
- PSOs will record watch effort and environmental conditions on a routine basis.
- Members of the PSO and/or APSO team will consult with NMFS' NARW reporting system for the presence of NARWs in the Project Area.

11.1.3 Visual Monitoring During Vessel Transit

- PSOs and/or trained vessel crew will observe for marine mammals at all times when vessels are transiting to/from and within the Project Area and port.
- PSOs and/or vessel crew will request vessel-strike avoidance measures if necessary (Section 11.1.5).

11.1.4 Acoustic Monitoring

Acoustic monitoring and mitigation measures stated below will be followed during WTG and OSP foundation installation requiring pile driving only.

11.1.4.1 Passive Acoustic Monitoring Methods

- APSOs will rotate on a 4-hour basis when monitoring from a 24-hour operation vessel or base of operations.
- A real-time PAM system will be used to supplement visual monitoring during all pre-start clearance, piling, and post-piling monitoring periods.
- Use of PAM will allow initiation of pile driving when visual observation of the entire pre-start clearance zone is not possible due to poor visibility, including darkness during nighttime operations.
- There will be one APSO on duty during both daytime and nighttime/low visibility monitoring.
- APSOs will immediately communicate all acoustic detections of marine mammals to PSOs performing visual observations including any determination regarding species identification, distance, and bearing of the marine mammal.

- The PAM system will not be located on the pile installation vessel to reduce masking of marine mammal sounds.
- A detailed description of the real-time PAM system will be developed and submitted to NMFS and BOEM for review and approval.

11.1.4.2 *Sound Source Verification*

A detailed plan for Sound Source Verification (SSV) will be developed and submitted to NMFS prior to planned start of pile driving and UXO detonations.

- Pile Driving
    - Measurement of each pile type (monopiles and/or piled jackets) to be installed to determine the sound levels produced and effectiveness of the NAS(s).
    - Procedures for how measurement results will be used to justify any requested changes to planned monitoring and mitigation distances.
    - Measurements of received levels will be taken at 750 m and other various distances and azimuths relative to the pile location designed to gather data on sounds produced during installation scenarios specific to the Project (Figure 14). These measurements will be used to validate the modeled sound levels at 750 and other distances as provided in Appendix G1 of Appendix A to this application. These measurements are designed to assess whether or not the distances to the Level A and Level B harassment isopleths and/or other mitigation action distances align with the distances modelled.
        - SSV will include at least one recorder in each of the four azimuths around the pile (to capture potential directivity of the sound field). Additionally, there will be 3-4 recorders (one bottom and one mid-water column at each location) along one azimuth that is likely to see the lowest propagation loss to allow assessment of the modelled Level A and Level B isopleths.
- UXO Detonation
    - Measurements will be made for each UXO/MEC that must be detonated using the method described above for pile driving.

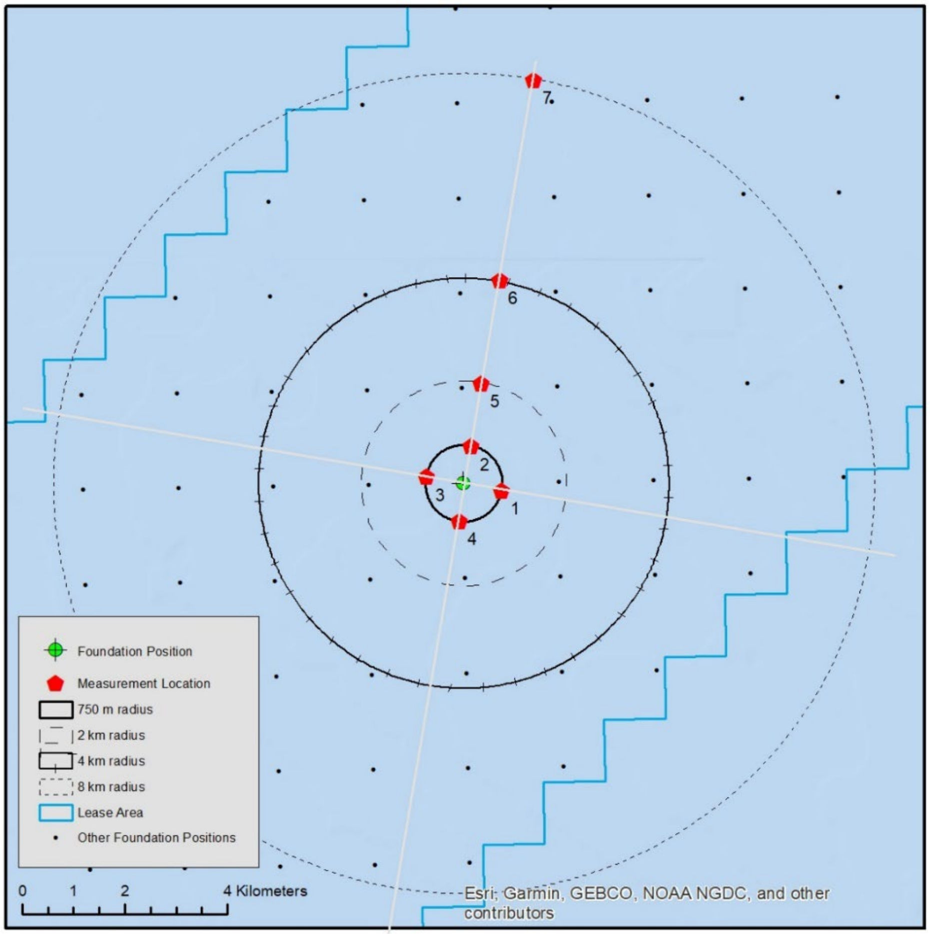

Figure 14. Conceptual design of sound source verification measurement locations relative to a foundation installation.

11.1.5 Vessel Strike Avoidance

All vessels, including those transiting to and from local ports and the Project Area, will follow the vessel strike avoidance measures outlined below, except in cases where following these requirements would put the safety of the vessel or crew at risk.

11.1.5.1 General Measures

- Captain, first mate, and/or designated vessel personnel working offshore will receive training on marine mammal awareness and vessel strike avoidance measures.
- All vessels will have a minimum of one dedicated observer on watch (NMFS-approved PSO or trained crew member with no other concurrent duties) with standard equipment for daytime monitoring (handheld binoculars) and alternative equipment for low visibility conditions (night-vision devices and/or IR sensor). The dedicated observers will be trained in detection and identification of protected species, vessel strike minimization procedures and how and when to communicate with the vessel operator.
- Observers will maintain a vigilant watch for all marine mammals and slow down, change course, slow down or stop vessels to avoid striking protected species.

- PSOs, vessel captains or operators, and dedicated visual observers will continuously monitor all NMFS NARW reporting systems (Right Whale Sighting Advisory System [RWSAS], WhaleAlert, and VHF channel 16).

11.1.5.2 Separation Distances

- Vessels will maintain, to the extent practicable, separation distances of:
    - >500 m distance from any sighted NARW or an unidentified large marine mammal,
    - >100 m from sperm whales and all other baleen whales,
    - >50 m from all other marine mammals, with the exception of animals approaching the vessel (e.g., delphinids and pinnipeds), in which case the vessel operator must avoid excessive speed or abrupt changes in direction.

11.1.5.3 Actions given observed marine mammal

- If underway, all vessels will steer a course away from any sighted NARW at a distance greater than 500 m from the vessel and immediately leave the area at a slow safe speed (10 kts or less):
    - If a NARW comes within 500 m of an underway vessel, the vessel will reduce speed and shift the engines into neutral, if safe to do so;
    - The vessel will not engage engines until the NARW has moved outside of the vessel's path and beyond the 500 m minimum separation distance;
    - If the vessel is stationary, the vessel will not engage engines until the NARW has moved beyond 500 m;
    - If a whale is observed but cannot be confirmed as a species other than a NARW, the vessel operator will assume that it is a NARW and take the appropriate mitigation measures as described above.
- If a vessel comes within 100 m of a non-NARW whale:
    - If underway, the vessel must attempt to remain parallel to the animal's course, reduce speed and shift the engine to neutral, if safe to do so, and must not engage the engines until the whale (e.g., large whale and/or ESA-listed whales besides NARW) has moved outside of the vessel's path and beyond 100 m.
    - If stationary, the vessel must not engage engines until the whale has moved beyond 100 m.
- All underway vessels will, to the maximum extent practicable, attempt to maintain a separation distance of 50 from all delphinid cetaceans and pinnipeds with the exception made for those that approach the vessel (e.g., bow riding dolphins).
    - Underway vessels will not divert to approach any small cetacean, seal, sea turtle, or giant manta ray;
    - If a delphinid cetacean that is not bow riding or a pinniped is sighted within 50 m of an underway vessel, that vessel will shift the engine to neutral. Engines will not be engaged until the animal(s) has moved outside of the vessel's path and beyond 50 m.
- All sightings of dead or injured marine mammals or sea turtles will be reported within 24 hours (Section 11.1.7).

11.1.5.4 Speed Reduction

- Vessels will comply with current mandatory measures stipulated in the NOAA NARW Vessel Strike Reduction Regulations;
- All vessels, regardless of size, will transit at 10 knots or less within any active NARW SMA and Slow Zone (i.e., DMA or acoustically-triggered Slow Zones)
- During migratory and calving periods from **November 1 to April 30**, all project vessels will operate at 10 knots or less when in the Project Area;
- All vessel speeds will be reduced to ≤10 kts when mother/calf pairs, pods, or large assemblages of marine mammals are observed;
- SouthCoast Wind will implement (or participate in a joint program, if developed) a PAM system designed to detect NARW within the transit corridor and additional visual monitoring measures as described below. A Vessel Strike Avoidance Plan that provides a more detailed description of the equipment and methods to conduct the monitoring summarized here will be provided to NMFS at least 90-days prior to commencement of vessel movements associated with the activities covered by the requested incidental take regulations.
  - Acoustic Monitoring
    - A PAM system consisting of near real-time bottom mounted and/or mobile acoustic monitoring systems will be installed such that NARW and other large whale calls made in or near the corridor can be detected and transmitted to the transiting vessel (either directly or through an operations base).
    - The detections will be used to determine areas along the transit corridor where vessels would be allowed to travel at >10 kts when no other speed restrictions are in place (e.g., 10 knot speed restriction in SMAs and DMAs);
    - Any detection of a large whale (including NARW) via the PAM system within the transit corridor will trigger a 10 knot or less speed restriction for all Project vessels until the whale can be confirmed visually beyond 500 m of the vessel or 24 hours following the detection and any re-detection has passed.
  - If the PAM system temporarily stops working the following procedures will be followed.
    - All vessels, regardless of size, will transit at <10 kts in all SMAs (applicable November 1st to April 30th) and DMAs (at any time of year).
    - Between May 1 and October 31, all vessels, regardless of size, will transit at >10 kts and implement the visual monitoring measures with a dedicated observers as described above.

11.1.6 Data Recording

- All data will be recorded based on standard PSO collection requirements using industry-standard software.
- Data recorded will include information related to ongoing operations, observation methods and effort, visibility conditions, marine mammal detections, and any mitigation actions requested and enacted.

11.1.7 Reporting

The following situations would require reporting as defined below:

- If a stranded, entangled, injured, or dead protected species is observed, the sighting will be reported immediately and within 24 hours to NMFS Sighting Advisory System (SAS) hotline.
- Any NARW sightings will be reported as soon as feasible and no later than within 24 hours to the NMFS Right Whale Sighting Advisory System (RWSAS) hotline (866-755-6622) or via the Whale Alert Application.
- If a marine mammal is taken in a prohibited manner by Project activities, the following actions will occur:
    - Activity operations resulting in the injury/death will cease immediately.
    - The incident will be reported to the NMFS OPR (301-427-8401), NMFS New England Stranding Network Coordinator, and the Greater Atlantic Regional Fisheries Office (GARFO) no later than within 24 hours.
    - Additional reporting by the vessel captain or PSO onboard will be to NMFS Fisheries Marine Mammal and Sea Turtle Stranding and Entanglement Hotline (866-775-6622), or alternative electronic reporting systems as approved by the NMFS stranding program, as well as the U.S. Coast Guard (USCG).
    - The report will include all available information required by the ITR or the NMFS stranding report form.
    - SouthCoast Wind will not resume the activity which resulted in the injury until NMFS OPR is able to review the circumstances of the incident determine the appropriate course of action.
- Actions given an unknown and recent observed dead or injured marine mammal:
    - SouthCoast Wind will immediately report the incident to the NMFS OPR and the NMFS New England Stranding Network Coordinator (as stated above).
    - The report will include the same information identified for a take by construction activity.
    - Activities will continue while NMFS reviews the circumstances of the incident and works with SouthCoast Wind to determine whether modifications to the activities are appropriate.
- Actions given observation of a dead or injured marine mammal not associated with or related to construction activities:
    - SouthCoast Wind will report the incident to the NMFS OPR and the NMFS New England Stranding Network Coordinator, within 24 hours of the discovery.
    - SouthCoast Wind will include any documentation of the stranded animal sighting to NMFS and the Marine Mammal Stranding Network including photographs and video footage if available.
    - Construction activities may continue.

11.1.7.1 Data and Final Reports will be prepared using the following protocols:

- All vessels will utilize a standardized data entry format.
- A quality assurance/ quality control (QA/QC'd) database of all sightings and associated details (e.g., distance from vessel, behavior, species, group size/composition) within and

outside of the designated shutdown zone, monitoring effort, environmental conditions, and Project-related activity will be provided after field operations and reporting are complete.

- During all pile driving activities, weekly reporting summarizing sightings, detections, and activities will be provided to NMFS and BOEM on the Wednesday following a Sunday-Saturday period.
- Monthly reports will be required during all pile driving activities including all information in the weekly reports, including project activities carried out in the previous month, vessel transits (number, type of vessel MMSI number and route), number of piles installed, all detections of marine mammals, and any mitigative actions taken.
- Monthly reports will be submitted to NMFS on the 15th of the month for the previous month.
- Final reports will follow a standardized format for PSO reporting from activities requiring marine mammal mitigation and monitoring.
- An annual report summarizing the prior year's activities will be provided to NMFS and BOEM 90-days after completion of each 12-month period during the effectiveness of the ITRs.

11.2 WTG and OSP Foundation Installation

Monitoring and mitigation protocols applicable to impact and vibratory pile driving during SouthCoast Wind construction are described further in the following subsections. Impact and vibratory pile driving may be initiated after dark or during daytime reduced visibility periods following the protocols in Section 11.2.3 and Section 11.2.4.

11.2.1 Monitoring Equipment

The following types of equipment will be used to monitor for marine mammals from one or more locations.

- Reticle binoculars
- Mounted thermal/IR camera system
  - The camera systems may be automated with detection alerts that will be checked by a PSO on duty; however, cameras may not be manned by a dedicated observer.
- Mounted "big-eye" binocular
- Monitoring station for real time PAM system (impact pile driving only)
- The selected PAM system will transmit real time data to PAM monitoring stations on the vessels and/or shore side monitoring station.
- Hand-held or wearable NVDs
- IR spotlights
- Data collection software system
- PSO-dedicated VHF radios
- Digital single-lens reflex camera equipped with 300-mm lens

11.2.2 Daytime Visual Monitoring

Visual monitoring will occur from the construction vessel and two dedicated PSO vessels. Daytime visual monitoring is defined by the period between nautical twilight rise and set for the region. Visual monitoring measures below intend to provide complete visual coverage of the pre-start clearance zone during the pre-start clearance period prior to pile driving and the shutdown zones during impact and vibratory pile driving. The following visual monitoring protocols include:

- Three on duty PSOs will keep watch from each platform (the pile driving vessel and two PSO vessels) during the pre-start clearance period, throughout pile driving, and 30 minutes after piling is completed.
- At least three PSOs on duty on each platform during all other daylight periods.
- PSOs will monitor for at least 60 minutes before, during, and 30 minutes after each piling event.
- One PSO will monitor areas closer to the pile being stalled for smaller marine mammals using the naked eye, reticle binoculars and/or other electronic method(s) while two PSOs scan farther from the pile using the mounted big eye binoculars and/or other electronic method(s).
- PSO will monitor the NMFS NARW reporting systems including WhaleAlert and SAS once every 4-hour shift during Project related activities.

11.2.3 Daytime Periods of Reduced Visibility

These measures will apply during the pre-start clearance period, during active pile driving, and 30 minutes after piling is completed.

- If the Level B harassment zone is obscured, the three PSOs on watch will continue to monitor the shutdown zone utilizing thermal camera systems and/or other electronic method(s) and PAM.
- During nighttime or low visibility conditions, the three PSOs on watch will monitor the shutdown zone with the mounted IR camera (further described in 11.2.4), available handheld night vision, and/or other electronic method(s).
- All on-duty PSOs will be in contact with the APSOs who will monitor the PAM systems for acoustic detections of marine mammals that are vocalizing in the area (impact pile driving only).

11.2.4 Nighttime Visual Monitoring

During nighttime operations, night vision equipment (night vision goggles) and infrared/thermal imaging technology will be used. Recent studies have concluded that the use of infrared/thermal imaging technology allow for the detection of marine mammals at night (Verfuss et al. 2018). Guazzo et al (2019) showed that probability of detecting a large whale blow by a commercially available infrared camera was similar at night as during the day; camera monitoring distance was 2.1 km (1.3 mi) from an elevated vantage point at night versus 3 km (1.9 mi) for daylight visual monitoring from the same location. The following nighttime piling monitoring and mitigation methods use the best currently available technology to mitigate potential impacts and result in the least practicable adverse impact.

- During nighttime operations, visual PSOs on-watch will work in three person teams observing with an NVDs and/or monitoring IR thermal imaging camera systems. There will also be an APSO on duty conducting acoustic monitoring in coordination with the visual PSOs.

- The PSOs on duty will monitor for marine mammals and other protected species using night-vision goggles with thermal clip-ons, a hand-held spotlight (one set plus a backup set) and/or other electronic method(s), such that PSOs can focus observations in any direction.
- If possible, deck lights will be extinguished or dimmed during night observations when using the NVDs (strong lights compromise the NVD detection abilities); alternatively, if the deck lights must remain on for safety reasons, the PSO will attempt to use the NVDs in areas away from potential interference by these lights.

SouthCoast will prepare a more detailed description of the anticipated efficacy of the technologies it intends to use during nighttime monitoring and describe how they will be used to monitor the pre-start clearance and shutdown zones. This will be provided to NMFS after publication of the draft ITRs so that it can be considered during preparation of the Final ITRs.

11.2.5 Acoustic Monitoring

Since visual observations within the applicable shutdown zones can become impaired at night or during daylight hours due to fog, rain, or high sea states, visual monitoring with thermal and NVDs will be supplemented by PAM during these periods. An APSO will be on watch during all pre-start clearance, piling, and post-piling monitoring periods (daylight, reduced visibility, and nighttime monitoring). A combination of alternative monitoring measures, including PAM, has been demonstrated to have comparable detection rates (although limited to vocalizing individuals) to daytime visual detections for several species (Smith et al., 2020).

- There will be one APSO on duty who will begin monitoring at least 60 minutes prior to initiation of pile driving, continue throughout piling, and extend at least 30 minutes post installation during both daytime and nighttime/low visibility conditions; All on-duty PSOs will be in contact with the APSO on duty, who will monitor the PAM systems for acoustic detections of marine mammals that are vocalizing in the area.
- For real-time PAM systems, at least one APSO will be designated to monitor each system by viewing data or data products that are streamed in real-time or near real-time to a computer workstation and monitor located on a Project vessel or onshore.
- The PAM operator will inform the PSOs on duty of animal detections approaching or within the applicable mitigation zones via the data collection software system (i.e., Mystcetus or similar system) or other direct forms of communication (radio, phone, messaging app). The PSO will then be responsible for requesting that any necessary mitigation procedures are implemented.
- The PAM system will have the capability of monitoring up to 10 km from the pile.
- A PAM Plan will be submitted to NMFS and BOEM prior to the planned start of pile driving.

11.2.6 Pre-Start Clearance

A pre-start clearance period will be implemented for all foundation installation occurring both inside and outside the 20-km area of concern (as described in Section 1). For foundations installed within the 20-km area of concern (June 1 through October 15), a minimum visibility zone[1] of 4,900 m for pin pile and 7,500 m for monopile installation will be implemented. For OSP foundations (and WTG jacket foundations, if installed) installed throughout the rest of the Lease Area (outside the area of concern), a minimum visibility zone[2] of 2,600 m for pin pile and 3,700 m for monopile and pin pile installation will be implemented. For impact pile driving, PAM will begin 60 minutes prior to the start of pile driving. Pre-start clearance zones will follow the same zone sizes as presented below in Section 11.2.9.

- Visual monitoring will begin at least 60 minutes prior to the start of impact pile driving and 30 minutes prior to the start of vibratory pile driving;
- To begin the clearance process, PSOs will visually clear (i.e., confirm no observation of marine mammals) the relevant minimum visibility zone for 30 minutes immediately prior to commencing foundation installation activities.
    - If PSOs cannot visually monitor the relevant minimum visibility zone prior to the start of pile driving, pile driving operations will not commence.
- Once the clearance process has begun, visual monitoring will be conducted (including the use of IR and NVD systems, as appropriate) and PAM for at least 60 minutes prior to the start of soft-start;
- If a marine mammal is observed entering or within the relevant clearance zone, pile driving activity will be delayed.
- An acoustic detection localized to a position within the relevant clearance zone(s) will trigger a delay.
- Impact and/or vibratory pile driving may commence when either the marine mammal(s) has voluntarily left the specific clearance zone and been visually or acoustically confirmed beyond that clearance zone, or, when the additional time period has elapsed with no further sighting or acoustic detection (i.e., 15 minutes for odontocetes [excluding sperm whales] and pinnipeds, and 30 minutes for sperm and baleen whales [including NARWs]).
    - In cases where these criteria cannot be met, pile driving may restart only if necessary to maintain pile stability at which time SouthCoast Wind will use the lowest hammer energy practicable to maintain stability.

11.2.7 Soft Start

- Soft start procedures will be followed, to the extent practicable, at the beginning of each pile driving event or any time pile driving has stopped for longer than 30 minutes.
- A soft start procedure will not begin until the relevant clearance zone has been cleared by the visual PSO or APSOs.
- If a marine mammal is detected within or about to enter the relevant clearance zone, prior to or during the soft-start procedure, pile driving will be delayed until the animal has been

[1] The minimum visibility zone sizes implemented during foundation installation of pin piles and monopiles within the 20-km area of concern are set equal to the largest Level B harassment zone (unweighted acoustic ranges to 160 dB re 1 µPa sound pressure level in summer) modeled at for each substructure type assuming 10 dB of noise attenuation.
[2] The minimum visibility zone sizes implemented during foundation installation of pin piles and monopiles occurring throughout the rest of the Lease Area (outside the area of concern) are set equal to the second largest low-frequency Level A SEL_{cum} exposure ranges ($ER_{95\%}$) with 10 dB of noise attenuation for foundation installation across Year 1 and Year 2.

observed exiting the relevant clearance zone or until an additional time period has elapsed with no further sighting (i.e., 15 minutes for odontocetes [excluding sperm whales] and pinnipeds and 30 minutes for sperm and baleen whales [including NARWs]).

11.2.8 Shutdowns

- If conditions change such that PSOs cannot monitor the relevant shutdown zone following the commencement of pile driving, the PSO will request an immediate shutdown.
- If a marine mammal is detected entering or within the respective shutdown zone after pile driving has commenced, an immediate shutdown of pile driving will be requested unless the Chief Engineer or Vessel Captain determine shutdown is not feasible.
- If a shutdown is not feasible at that time in the installation process due to a risk of injury or loss of life to an individual or risk of damage to a vessel that creates risk of injury or loss of life for individuals, or the risk of jeopardizing the installation process (pile refusal or instability), a reduction in the hammer energy of the greatest extent possible will be implemented.
- The shutdown zone will be continually monitored by PSOs and APSOs during any pauses in pile driving.
- If a marine mammal is sighted within the shutdown zone during a pause in piling, resumption of pile driving will be delayed until the animal(s) has exited the relevant shutdown zone or an additional time period has elapsed with no further sighting of the animal that triggered the shutdown (15 minutes for odontocetes [excluding sperm whales] and pinnipeds and 30 minutes for sperm and baleen whales [including NARWs]).
- Following shutdown, pile driving will restart using the same procedure described above in Section 11.2.7.

11.2.9 Shutdown Zones

The shutdown zones below (Section 11.2.9.1 through 11.2.9.6) are based upon the Level A exposure ranges with 10 dB of noise attenuation for foundation installation across Year 1 and Year 2 (further details in Section 6.3). If the shutdown zone is equivalent to the "NAS perimeter", this means the outside perimeter of the NAS. Therefore, any animals occurring within the NAS would trigger a shutdown. The NARW shutdown zones (Section 11.2.9.1 through 11.2.9.6) are based on the requirement that a visual or acoustic observation of a NARW at any distance will result in immediate shutdown measures described in Section 11.2.8. Foundation installations include 9/16 m (tapered) diameter WTG monopiles and 4.5 m WTG and OSP jacket pin piles installed using impact pile driving only during Year 1. During Year 2, foundations may be installed using only impact pile driving or may use a combination of vibratory and impact pile driving. The shutdown zones are the largest zone sizes expected to result from foundation installations for each installation schedule, except in cases where a single species (e.g. fin whales) had a much larger modeled exposure range than other large cetaceans and the next largest zone size was selected. If smaller diameter piles, lower maximum hammer energies and/or total strikes per pile, or more effective NAS are decided upon and used during the construction activities, modeled Level A exposure ranges applicable to those revised parameters would be used, likely resulting in shorter shutdown zone distances than those shown below based on current maximum pile size and hammer energy assumptions.

11.2.9.1 WTG Monopile and WTG Jacket Installations Using Only Impact Driving in Summer

WTG Monopile Impact Driving

- Low-Frequency Cetaceans: 3,500 m
- NARW: At any distance
- Mid-Frequency Cetaceans: NAS perimeter
- High-Frequency Cetaceans: NAS perimeter
- Seals: 200 m

WTG Jacket Impact Driving

- Low-Frequency Cetaceans: 2,000 m
- NARW: At any distance
- Mid-Frequency Cetaceans: NAS perimeter
- High-Frequency Cetaceans: NAS perimeter
- Seals: NAS perimeter

11.2.9.2 WTG Monopile and WTG Jacket Installations Using Only Impact Driving in Winter

WTG Monopile Impact Driving

- Low-Frequency Cetaceans: 3,700 m
- NARW: At any distance
- Mid-Frequency Cetaceans: NAS perimeter
- High-Frequency Cetaceans: NAS perimeter
- Seals: 200 m

WTG Jacket Impact Driving

- Low-Frequency Cetaceans: 2,300 m
- NARW: At any distance
- Mid-Frequency Cetaceans: NAS perimeter
- High-Frequency Cetaceans: NAS perimeter
- Seals: 400 m

11.2.9.3 WTG Monopile and Jacket Foundations using Combined Vibratory and Impact Driving (Year 2 only) in Summer

WTG Monopile during Impact driving

- Low-Frequency Cetaceans: 3,500 m
- NARW: At any distance
- Mid-Frequency Cetaceans: NAS perimeter
- High-Frequency Cetaceans: NAS perimeter
- Seals: 200 m

WTG Monopile during Vibratory driving

- Low-Frequency Cetaceans: 200 m
- NARW: At any distance
- Mid-Frequency Cetaceans: NAS perimeter
- High-Frequency Cetaceans: NAS perimeter
- Seals: NAS perimeter

WTG Jacket during Impact driving

- Low-Frequency Cetaceans: 1,900 m
- NARW: At any distance
- Mid-Frequency Cetaceans: NAS perimeter
- High-Frequency Cetaceans: NAS perimeter
- Seals: NAS perimeter

<u>WTG Jacket during Vibratory driving</u>

- Low-Frequency Cetaceans: NAS perimeter
- NARW: At any distance
- Mid-Frequency Cetaceans: NAS perimeter
- High-Frequency Cetaceans: NAS perimeter
- Seals: NAS perimeter

11.2.9.4 *Concurrent Installation of One WTG Monopile and Four OSP Jacket Pin Piles in Summer*

<u>WTG Monopile during Impact driving</u>

- Low-Frequency Cetaceans: 3,500 m
- NARW: At any distance
- Mid-Frequency Cetaceans: NAS perimeter
- High-Frequency Cetaceans: NAS perimeter
- Seals: 300 m

11.2.9.5 *Concurrent Installation of Four WTG Jacket Pin Piles and Four OSP Jacket Pin Piles in Summer*

<u>WTG Jacket during Impact driving</u>

- Low-Frequency Cetaceans: 2,600 m
- NARW: At any distance
- Mid-Frequency Cetaceans: NAS perimeter
- High-Frequency Cetaceans: NAS perimeter
- Seals: 200 m

11.2.10Post-Piling Monitoring

- PSOs will continue to survey the shutdown zone throughout the duration of pile installation and for a minimum of 30 minutes after piling has been completed.

11.2.11 Noise Attenuation

Several recent studies summarizing the effectiveness of noise attenuation systems (NAS) have shown that broadband sound levels are likely to be reduced by anywhere from 7 to 17 dB, depending on the environment, pile size, and the size, configuration and number of systems used . The single bubble curtain applied in shallow water environments regularly achieves 7-8 dB broadband attenuation (Lucke et al. 2011; Rustemeier et al. 2012; Bellmann 2014; Bellman 2019). More recent in situ measurements during installation of large monopiles (~8 m) for WTGs in comparable water depths and conditions indicate that attenuation levels of 10 dB are readily achieved for a single bubble curtain (Bellman 2019; Bellmann et al. 2020). Large bubble curtains tend to perform better and more reliably, particularly when deployed with two rings (Koschinski and Ludemann 2013; Bellmann 2014; Nehls et al. 2016). A California Department of Transportation study tested several small, single, bubble curtain systems and found that the best attenuation systems resulted in 10-15 dB of attenuation (Buehler et al. 2015). Buehler et al. (2015) concluded that attenuation greater than 10 dB could not be reliably predicted from small, single, bubble curtains because sound transmitted through the seabed and re-radiated into the water column is the dominant sound in the water for bubble curtains deployed immediately around the pile. Combinations of systems (e.g., double big bubble curtain, hydrodsound damper plus single big bubble curtain) potentially achieve much higher attenuation. The type and number of NAS to be used during construction have not yet been determined. Based on prior measurements this combination of NAS are reasonably expected to achieve far greater than 10 dB broadband attenuation of impact pile driving sounds. SouthCoast Wind will operate NAS to meet noise levels modeled (10 dB attenuation) and will not exceed these levels. However, if SSV suggests noise levels are louder than modeled, additional noise attenuation measures will be implemented to further reduce noise levels to at least those modeled.

11.2.12 Sound Source Verification

- SSV measures will be followed as stated in Section 11.1.4.2.

11.2.13 Potential Additional Measures to Protect North Atlantic Right Whales

To complete installation within as few years as possible during the multiple year installation campaign expected for the entire Lease Area build-out, impact pile driving 24-hours per day is deemed necessary.

- The period from January through April is when the highest number of NARW are present in the region which means foundation installations during this period would likely result in greater potential impacts to this species. To reduce the need for foundation installations during this period and associated impacts to the NARW, SouthCoast Wind may conduct nighttime pile driving of monopile or piled jacket foundations during time periods when the fewest number of NARW are likely to be present in the region. Specific measures will include:
    - Concentrating pile driving activities when NARW are less likely to be present within the region (May 15 through December 31), including in the Lease Area.
    - Specific monitoring tools and plans will be developed as a part of the ongoing ITR Application process, but may include the use of advanced infrared systems, near real-time PAM, autonomous underwater vehicles, autonomous aerial vehicles, or other advanced technologies that could improve the probability of detecting marine mammals at night.

As a result of concerns related to potential NARW use of the Nantucket Shoals region outside of the January–April period, additional mitigation and monitoring measures have been proposed in a NARW mitigation and monitoring plan for pile driving. These measures include the commitment to only use impact pile driving in specified areas of the Lease Area (Project 1) and to monitor and mitigate for NARW within the Level B disturbance zones for impact pile driving. These measures also include a commitment that no pile driving for foundation installations will occur from January 1 through May 14 each year. On top of the seasonal description described, no pile driving for WTG or OSP foundation installations will occur within the 20-km area of concern during the month of May or after October 15.

Please refer to the *Supplemental North Atlantic Right Whale Monitoring and Mitigation Plan for Pile Driving* submitted separately for additional details.

11.3 HRG Surveys

HRG survey activities may be required during construction and the operations and maintenance (O&M) phases of the Project. When necessary, HRG survey operations will be conducted 24-hours per day, although some vessels may only operate during daylight hours. The following mitigation and monitoring measures for HRG surveys apply only to sound sources with operating frequencies below 180 kHz. There are no mitigation or monitoring protocols required for sources operating >180 kHz.

Additionally, shutdown, pre-start clearance, and ramp-up procedures will not be conducted during HRG operations using only non-impulsive sources (e.g., USBL and parametric sub-bottom profilers) other than non-parametric sub-bottom profilers (e.g., CHIRPs). Pre-start clearance and ramp-up, but not shutdown will be conducted when using non-impulsive, non-parametric sub-bottom profilers.

11.3.1 Monitoring Equipment

- Two pairs of reticle binoculars;
- Two hand-held or wearable night vision devices (NVDs);
- Two IR spotlights;
- One data collection software system;
- Two PSO-dedicated very high frequency (VHF) radios;
- One digital single-lens reflex camera equipped with a 300-mm lens.

11.3.2 Visual Monitoring

- Four PSOs on board any 24-hour survey vessels.
- Two PSOs on board any daylight survey vessels.
- One PSO on watch during all daylight surveying.
- Two PSOs on watch during nighttime surveying.
- Vessels conducting activities in very-shallow waters:
  - One visual PSO will be onboard
  - The vessel captain (or crew member on watch) will conduct observations when the PSO is on required breaks;
  - The PSO on duty will remain available to confirm sightings and any related mitigation measures while on break.
- PSOs will begin observation of the shutdown zones prior to initiation of HRG survey operations and will continue throughout the survey activity and/or while equipment operation below 180 kHz is in use.
- PSO will monitor the NMFS NARW reporting systems including WhaleAlert and SAS once every 4-hour shift during Project related activities.

11.3.3 Daytime Visual Monitoring

The following protocols will be applied to visual monitoring during daytime surveys:

- One PSO on watch during pre-start clearance periods and all source operations.

- PSOs will use reticle binoculars and the naked eye to scan the shutdown zone for marine mammals.

11.3.4 Nighttime and Low Visibility Monitoring

Visual monitoring during nighttime surveys or periods of low visibility will utilize the following protocols:

- The Lead PSO will determine if conditions warrant implementing reduced visibility protocols.
- Two PSOs on watch during pre-start clearance periods, all operations, and for 30 minutes following use of HRG sources operating below 180 kHz.
- Each PSO will monitor for marine mammals and other protected species using night-vision goggles with thermal clip-ons and a hand-held spotlight (one set plus a back-up set), such that PSOs can focus observations in any direction.

11.3.5 Shutdown Zones

PSOs will establish and monitor marine mammal shutdown zones. Distances to shutdown zones will be from any acoustic sources, not the distance from the vessel. Shutdown zones will be as follows:

- 500 m from NARW for use of impulsive acoustic sources (e.g., boomers and/or sparkers) and non-impulsive nonparametric sub-bottom profilers; and
- 100 m from all other marine mammals for use of impulsive acoustic sources (e.g., boomers and/or sparkers), except for delphinids when approaching the vessel or towed acoustic sources, shutdown is not required.

11.3.6 Pre-Start Clearance

PSOs will establish and monitor pre-start clearance zones. Distances to pre-start clearance zones for HRG surveys will be the same as those for shutdown zones described above.

- PSOs will conduct 30 minutes of pre-start clearance observation prior to the initiation of HRG operations.
- The pre-start clearance zones must be visible using the naked eye or appropriate technology during the entire pre-start clearance period for operations to start. If the pre-start clearance zones are not visible, source operations <180 kHz will not commence.
- Ramp-up may not be initiated if any marine mammal(s) is detected within its respective pre-start clearance zone.
- If a marine mammal is observed entering or within the pre-start clearance zones during the pre-start clearance period, relevant acoustic sources must not be initiated until the marine mammal(s) is confirmed by visual observation to have exited the relevant zone, or, until an additional time period has elapsed with no further sighting of the animal (15 minutes for odontocetes [excluding sperm whales] and pinnipeds and 30 minutes for sperm and baleen whales [including NARWs]).

11.3.7 Ramp-Up

- The ramp-up procedure will not be initiated during periods of inclement conditions or if the pre-start clearance zones cannot be adequately monitored by the PSOs, using the appropriate visual technology for a 30-minute period immediately prior to ramp-up.
- Ramp-up will begin with the power of the smallest acoustic equipment at its lowest practical power output. When technically feasible, the power will then be gradually turned up and other acoustic sources added in a way such that the source level would increase gradually.
- Ramp-up activities will be delayed if marine mammal(s) enters its respective shutdown zone.
- Ramp-up will continue if the animal(s) has been observed exiting its respective shutdown zone, or until an additional time period has elapsed with no further sighting of the animal (15 minutes for odontocetes [excluding sperm whales], and 30 minutes for sperm and baleen whales [including NARW]).

11.3.8 Shutdowns

- Immediate shutdown of impulsive, non-parametric HRG survey equipment other than CHRIP sub-bottom profilers operating at frequencies <180 kHz is required if a marine mammal is observed within or entering the relevant shutdown zone.
- Any PSO on duty has the authority to call for shutdown of acoustic sources. When there is certainty regarding the need for mitigation action on the basis of visual detection, the relevant PSOs must call for such action immediately.
- Upon implementation of a shutdown, survey equipment may be reactivated when all marine mammals that triggered the shutdown have been confirmed by visual observation to have exited the relevant shutdown zone or an additional time period has elapsed with no further sighting of the animal that triggered the shutdown (15 minutes for odontocetes [excluding sperm whales] and pinnipeds, and 30 minutes for sperm and baleen whales [including NARWs]).
- If the acoustic source is shutdown for reasons other than mitigation (e.g., mechanical difficulty) for less than 30 minutes, the acoustic sources may be reactivated as soon as is practicable at full operational level if PSOs have maintained constant visual observation during the shutdown and no visual detections of marine mammals occurred within the applicable shutdown zone during that time.
- If the acoustic source is shutdown for a period longer than 30 minutes or PSOs were unable to maintain constant observation, then ramp-up and pre-start clearance procedures will be initiated as described in Sections 11.3.6 and 11.3.7.
- If delphinids are visually detected approaching the vessel or towed acoustic sources, shutdown is not required.

11.3.9 Sound Source Verification

- In 2019, NMFS expressed concerns with HRG sound source verification measurements previously collected in offshore wind leases in the Northeast and recommended developers requesting incidental take authorization to estimate zones of potential impact using standard modeling guidance (NMFS 2020e) SouthCoast Wind did not collect SSV measurements for 2019-2021 surveys and does not plan to collect SSV measurements as part of the planned surveys pre- and post-construction.

11.4 UXO Detonation

For UXOs that are positively identified in proximity to planned activities on the seabed, several alternative strategies will be considered prior to detonating the UXO in place. These may include relocating the activity away from the UXO (avoidance), moving the UXO away from the activity (lift and shift), cutting the UXO open to apportion large ammunition or deactivate fused munitions, using shaped charges to reduce the net explosive yield of a UXO (low-order detonation), or using shaped charges to ignite the explosive materials and allow them to burn at a slow rate rather than detonate instantaneously (deflagration). Only after these alternatives are considered would a decision to detonate the UXO in place be made. If deflagration is conducted, mitigation and a monitoring measure would be implemented as if it was a high order detonation based on UXO size. Decision on removal method will be made in consultation with a UXO specialist and in coordination with the agencies with regulatory oversite of UXO. For detonations that cannot be avoided due to safety considerations, a number of mitigation measures will be employed by SouthCoast Wind. No more than a single UXO will be detonated in a 24-hour period.

11.4.1 Monitoring Equipment

The equipment to be used during UXO detonations is shown in the table below (Table 58).

Table 58. Equipment use for all marine mammal monitoring vessels during pre-start clearance and post-detonation monitoring.

Item	Daytime Number on Each PSO Vessel
Reticle binoculars	2
Mounted "big-eye" binocular	1
Monitoring station for real time PAM system[1]	1
Data collection software system	1
PSO-dedicated VHF radios	2
Digital single-lens reflex camera equipped with 300-mm lens	1

PSO = protected species observer; VHF=very high frequency.

[1]The selected PAM system will transmit real time data to PAM monitoring stations on the vessels and/or a shore side monitoring station.

11.4.2 Pre-Start Clearance

All mitigation and monitoring zones assume the use of an NAS resulting in a 10 dB reduction of noise levels. Mitigation and monitoring zones specific to marine mammal hearing groups for the five different charge weight bins are presented in Table 59.

- A 60-minute pre-start clearance period will be implemented prior to any UXO detonation;

- The pre-start clearance zone (see distances to low-frequency cetacean thresholds in Table 59) must be fully visible for at least 60 minutes and all marine mammal(s) must be confirmed to be outside of the pre-start clearance zone for at least 30 minutes prior to commencing detonation;
- The pre-start clearance zone size will be dependent on the charge weight of the identified UXO, which will be determined prior to detonation. If the charge weight is determined to be unknown or uncertain, the largest pre-start clearance zone size (charge weight bin E12) will be used throughout the pre-start clearance period.
- All marine mammals must be confirmed to be out of the pre-start clearance zone prior to initiating detonation;
- If a marine mammal is observed entering or within the relevant pre-start clearance zones prior to the initiation of detonation, the detonation must be delayed;
- The detonation may commence when either the marine mammal(s) has voluntarily left the respective pre-start clearance zone and been visually confirmed beyond that pre-start clearance zone, or after 15 minutes for odontocetes [excluding sperm whales] and pinnipeds, and 30 minutes for sperm and baleen whales [including NARWs]) with no further sightings.

Table 59. Mitigation and Monitoring Zones Associated with In-Situ UXO Detonation of Binned Charge Weights, with a 10 dB Noise Attenuation System.

Marine Mammal Hearing Groups	UXO Charge Weight[1]										
	E4 (2.3 kg)		E6 (9.1 kg)		E8 (45.4 kg)		E10 (227 kg)		E12 (454 kg)		
	Pre-Start Clearance Zone[2] (m)	Level B Harassment Zone (m)	Pre-Start Clearance Zone (m)	Level B Harassment Zone (m)	Pre-Start Clearance Zone (m)	Level B Harassment Zone (m)	Pre-Start Clearance Zone (m)	Level B Harassment Zone (m)	Pre-Start Clearance Zone (m)	Level B Harassment Zone (m)	PAM Monitoring Zone (km)
Export Cable Corridor											
Low-Frequency Cetaceans	800	2,800	1,500	4,500	2,900	7,300	4,200	10,300	4,900	11,800	15
Mid-Frequency Cetaceans	100	500	200	800	300	1,300	500	2,100	600	2,500	15
High-Frequency Cetaceans	2,500	6,200	3,500	7,900	4,900	10,100	6,600	12,600	7,400	13,700	15
Phocid Pinnipeds	300	1,300	500	2,200	1,000	3,900	1,900	6,000	2,600	7,100	15
Lease Area											
Low-Frequency Cetaceans	400	2,900	800	4,700	1,800	7,500	3,400	10,500	4,300	11,900	15
Mid-Frequency Cetaceans	50	500	50	800	100	1,300	300	2,200	400	2,600	15
High-Frequency Cetaceans	2,200	6,200	3,200	8,000	4,900	10,300	7,200	12,900	8,700	14,100	15

Phocid Pinnipeds	100	1,500	200	2,400	600	3,900	1,200	6,000	1,600	7,000	15

kg = kilograms; m = meters

[1] UXO charge weights are groups of similar munitions defined by the U.S. Navy and binned into five categories (E4-E12) by weight (equivalent weight in TNT). For this assessment, four project sites (S1-S4) were chosen and modeled (see Hannay and Zykov 2021) for the detonation of each charge weight bin.

[2] Pre-start clearance zones were calculated by selecting the largest Level A threshold (the larger of either the PK or SEL noise metric). The chosen values were the most conservative per charge weight bin across each of the four modeled sites.

11.4.3 Visual Monitoring

- The number of vessels deployed will depend on the pre-start clearance zone size (as described in section 11.4.2) and safety set back distance from the detonation. A sufficient number of vessels will be deployed to cover the clearance and shutdown zones as described in Section 11.4.3.1 and Section 11.4.3.2.
- PSOs will visually monitor the relevant Low Frequency Cetacean pre-start clearance zone depending on the identified charge weight. This zone encompasses the maximum Level A exposure ranges for all marine mammal species except harbor porpoise, where Level A take has been requested due to the large zone sizes associated with High Frequency cetaceans.

11.4.3.1 Detonation Vessel Measures

- Three PSOs on duty on the detonation vessel;
- Three PSOs will maintain watch at all times during the pre-start clearance period and 30 minutes after the detonation event;
    - Each PSO will be responsible for monitoring a 120-degree sector with the unaided eye and reticle binoculars to provide additional coverage beyond the pre-start clearance zone away from the detonation location.
- The three visual PSOs onboard the detonation vessel will monitor out to the relevant pre-start clearance zone (shown in Table 59) at least 30 minutes prior to a detonation event; There will be a PAM operator on duty conducting acoustic monitoring in coordination with the visual PSOs during all pre-start clearance periods and post-detonation monitoring periods.

11.4.3.2 Additional PSO Vessel Measures

- Based on the relevant pre-start clearance zones (determined by the identified charge weight) for low-frequency cetaceans shown in Table 59, an additional PSO vessel will be used for UXO charge weight bins E10 and E12;
- The additional PSO vessel will circle the detonation vessel at or near the relevant pre-start clearance zone distance (4 – 5 km for charge weight bins E10 – E12);
- The additional PSO vessel will circumnavigate the detonation vessel at 7 – 10 knots during the pre-start clearance period, throughout the detonation event (as allowed by safety consideration), and during post-detonation monitoring;
- Visual monitoring will be conducted on the additional PSO vessel following the same methods as described above for the detonation vessel.
    - Additionally, the three PSOs on duty will be responsible for monitoring a 120-degree sector with the unaided eye and reticle binoculars to provide additional coverage inside the relevant pre-start clearance zone towards the detonation vessel as well as beyond the pre-start clearance zone away from the detonation location.

11.4.4 Acoustic Monitoring

- There will be one PAM team for all deployed PSO vessels;
- PAM will be conducted in the daylight only as no UXO will be detonated during nighttime hours;

- There will be a PAM operator stationed on at least one of the dedicated monitoring vessels (primary or secondary) in addition to the PSO; or located remotely/onshore;
- PAM will begin 60 minutes prior to a detonation event;
- PAM operator will be on duty during all pre-start clearance periods and post-detonation monitoring periods;
- Acoustic monitoring will extend beyond the Low Frequency Cetacean pre-start clearance zone for a given charge weight (Section 11.4.2);
- For real-time PAM systems, at least one PAM operator will be designated to monitor each system by viewing data or data products that are streamed in real-time or near real-time to a computer workstation and monitor located on a Project vessel or onshore;
- PAM operator will inform the Lead PSO on duty of animal detections approaching or within applicable ranges of interest to the detonation activity via the data collection software system;
- PAM devices used may include independent (e.g., autonomous or moored remote) systems.
- The PAM system will have the capability of monitoring up to 15 km from the detonation location.

11.4.5 Noise Attenuation

SouthCoast Wind will use an NAS for all detonation events as feasible and will strive to achieving the modeled ranges associated with 10 dB of noise attenuation (see Section 6.3.2). Zones without 10 dB attenuation would be implemented if use of a big bubble curtain was not feasible due to location, depth, or safety related constraints. If a NAS system is not feasible, SouthCoast Wind will implement mitigation measures for the larger unmitigated zone sizes with deployment of vessels adequate to cover the entire pre-start clearance zones.

11.4.6 Seasonal Restriction

- No UXO detonations are planned between January and April.

11.4.7 Post UXO Detonation Monitoring

- Post-detonation monitoring will occur for 30 minutes.

11.4.8 Sound Source Verification

- SSV measurements will be made for each UXO/MEC that must be detonated using the method summarized in Section 11.1.4.2.
- A sound field verification plan for UXO detonation will be submitted to NMFS 180 days prior to planned start of UXO detonations.

1. Introduction

SouthCoast Wind Energy LLC (SouthCoast Wind; formerly known as Mayflower Wind), a 50:50 joint venture between Shell New Energies US LLC and OW North America LLC, proposes an offshore wind renewable energy generation project (the Project) located in federal waters off the southern coast of Massachusetts in the Outer Continental Shelf (OCS) Lease Area OCS-A 0521 (Lease Area). The Project will consist of 149 positions to be occupied by wind turbine generators (WTGs) and offshore substation platforms (OSPs). This draft *SouthCoast Wind Avian and Bat Monitoring Framework* (the Framework) pertains to the offshore portions of the Project within the Lease Area only and does not apply to the offshore export cables, cable landfall sites, or onshore portions of the Project.

For the development of the Construction and Operations Plan (COP), SouthCoast Wind conducted an Avian Exposure Risk Assessment (COP Appendix I1) and a Bat Risk Assessment (COP Appendix I2). To support the development of the Avian Exposure Risk Assessment, SouthCoast Wind conducted high-definition aerial surveys of the Lease Area from November 2019 through October 2020. The data collected were based on images captured using a grid-based survey design with a 1.5-centimeter (cm) resolution ground sampling distance. Digital still imagery was captured during each survey, each of which employed a global positioning system (GPS)-linked camera platform using a flight management system to ensure the survey tracks were flown with a high degree of accuracy over the SouthCoast Wind Lease Area. The survey altitude was held at approximately 414.5 meters (m; 1,360 feet [ft]) to optimize coverage and minimize interference from cloud cover, and the aircraft was flown at a target ground speed of approximately 120 knots (kt) to reduce motion blur and ensure high image quality. The aerial digital survey captured images along nine lines spaced approximately 2 km across-track within the Lease Area and 1 nautical mile (nm) buffer. The captured images covered a minimum of 40% of the transect area per survey (i.e., approximately 6,233 hectares [15,403 acres]; sample area). Surveys were conducted monthly and sampling effort was increased during the migratory period for terns and other species of concern.

1.1 Avoidance, Minimization, and Mitigation Measures

SouthCoast Wind has taken steps to avoid, minimize, and mitigate impacts to birds and bats during Project construction, operation, and decommissioning. The Lease Area is located approximately 25 nm south of Martha's Vineyard and 20 nm south of Nantucket, Massachusetts. This offshore location for the siting of the WTGs and OSPs will help to avoid exposure to coastal birds and bats.

During construction, SouthCoast Wind will minimize lighting, to the extent practicable, to reduce potential attraction of birds and bats to vessels and structures. SouthCoast Wind will ensure that lighting on WTGs will be executed in accordance with Federal Aviation Administration (FAA) regulations and lighting on OSPs will be minimized to that required for navigation safety to reduce potential attraction of birds and bats to the extent practicable. During operations, SouthCoast Wind will significantly minimize Project lighting that would attract birds and bats by implementing an Aircraft Detection Lighting System (ADLS) that is expected to limit FAA and BOEM required lighting to less than five minutes per year (see COP Appendix Y3, Aircraft Detection Lighting System Efficacy Analysis).

1.2 Monitoring Goals and Objectives

This Framework serves to outline SouthCoast Wind's approach to post-construction avian and bat monitoring, overarching monitoring objectives, proposed monitoring elements, and reporting requirements. The measures proposed herein are intended to support the advancement of the understanding of bird and bat interactions and address the uncertainty on bird and bat use (particularly for federally listed species) of the offshore environment and the potential collision impacts from operating the offshore Project components. The scope of monitoring in this draft Framework is designed to meet federal requirements 30 CFR 585.626(b)(15) and 585.633(b) and is scaled to the size and risk profile of the Project with a focus on species of conservation concern (e.g., federally- and state-listed species). This draft Framework will also support the Bureau of Ocean Energy Management's (BOEM) Endangered Species Act Section 7 Consultation and the Environmental Impact Statement (EIS).

A detailed *Avian and Bat Post-Construction Monitoring Plan* (Monitoring Plan), based on this Framework, will be developed in coordination with BOEM, U.S. Fish and Wildlife Service (USFWS), and other relevant regulatory agencies as the National Environmental Policy Act (NEPA) process for the Project progresses. Where feasible, monitoring conducted in the Lease Area will be coordinated with monitoring at other offshore wind projects in the Massachusetts and Rhode Island Wind Energy Areas (MA/RI WEAs) to facilitate integrated analyses across a broader geographic area. **Table 1** below highlights the proposed avian and bat monitoring objectives and methods.

Table 1. Monitoring Objectives, General Approaches to be Used, and Types of Data Generated

Taxa	Monitoring Objective	Approach	Duration	Time of Year, Frequency	Coverage
Bats	Monitor occurrence of bats	Acoustics	At least 2 years	Late winter/ early spring – late fall/early winter, nightly to the extent practicable	Up to 2 OSPs
Birds	Monitor occurrence of birds	Acoustics	At least 2 years	Late winter/ early spring – late fall/early winter, nightly to the extent practicable	Up to 2 OSPs
Birds	Monitor occurrence of ESA-listed birds	Motus tags	At least 3 years	Continuous	TBD based on agency consultation
Birds	Monitor occurrence of nocturnal migratory birds	Radar	Up to 2 years	TBD based on agency consultation	One unit; location TBD
Birds	Monitor movement of marine birds around WTGs	Radar	Up to 2 years	TBD based on agency consultation	One unit; location TBD
Both	Document mortality	Incidental Observations	Project lifetime	Continuous	WTGs and OSPs

2. Bat Acoustic Monitoring

Although little is known about bat migration and movements over marine habitats, both historical and contemporary records have documented bat offshore activity in North America. Several bat species have been observed roosting on ships and offshore installations at sea (Stantec, 2018; Thompson et al., 2015; Ahlén et al., 2009) or at remote islands (Johnson et al., 2011; Cryan & Brown, 2007), suggesting some level of movements over water. SouthCoast Wind plans to conduct bat acoustic monitoring to assess bat activity within the Lease Area, targeting key data gaps related to species presence/composition, temporal patterns of activity, and correlation with weather and atmospheric conditions.

Acoustic monitoring of bat presence will be conducted for at least two years post-construction. Appropriate bat detector devices will be installed on various offshore Project components in the Lease Area (WTGs and OSPs) in early spring or late winter and removed in late fall or early winter after migration. SouthCoast Wind will work with BOEM, USFWS, and other relevant regulatory agencies to determine the optimal monitoring locations and durations. The detector devices will record calls of both cave-hibernating bats, including the northern long-eared bat (*Myotis septentrionalis*), and migratory tree bats. The resulting information can be used to identify bats to species. All acoustic data recorded will be processed with approved software to filter out poor-quality data and identify the presence of bat calls. High-frequency calls can then be classified by an experienced acoustician to the highest resolution possible (e.g., species, genus, family).

Collected bat call data will be identified and analyzed to understand relationships with time of day, season, and weather/atmospheric conditions to the extent practicable. The results will provide information on bat presence offshore and the conditions under which they may occur near offshore Project components.

3. Bird Acoustic Monitoring

Several bird groups are known to migrate offshore at night, including songbirds and shorebirds (Adams et al., 2015; Loring et al., 2021). However, there is limited understanding of the timing, species composition, and total avian abundance of these migratory movements offshore. Birds produce flight calls during migration, which are species-specific vocalizations given primarily during sustained flight (Farnsworth, 2005), and as a result, acoustic detectors can be used to study their presence in the Project Area. The detectors continuously record data during a pre-determined schedule, allowing for high-resolution species occurrence data.

SouthCoast Wind will conduct acoustic monitoring with detectors during the same period as bat acoustic monitoring (early spring or late winter – late fall or early winter, for at least two years of the Project). Due to noise interference with WTGs, bird acoustic detectors will only be installed on OSPs.

Collected bird acoustic data will be identified and analyzed to understand relationships with time of day, season, and weather/atmospheric conditions to the extent practicable. The results will provide information on bird presence offshore and the conditions under which they may occur near offshore Project components.

4. Motus Tracking Network and Use by ESA-Listed Birds Study

A total of 83 marine bird species are known to regularly occur off the coast of the eastern United States (Nisbet et al., 2013). SouthCoast Wind has conducted an Avian Exposure Risk Assessment (COP Appendix I1) to identify marine and coastal bird species listed as threatened or endangered under the Endangered Species Act (ESA), Massachusetts Endangered Species Act (MESA) (including Special Concern species) and/or Rhode Island Natural Heritage Program (RINHP) that may be present within the Offshore Project Area. To gain a better understanding of the presence and movements of ESA-listed birds in the Lease Area, SouthCoast Wind plans to install offshore automated telemetry receiving stations (Motus receivers) and contribute funding to Motus-tagging efforts to address this existing data gap. The exact species to be studied will be determined in consultation with federal agencies and will depend on existing, ongoing field efforts. The Motus receivers will also provide opportunistic presence/absence data on other species carrying Motus tags, such as migratory songbirds and bats.

Tagging efforts will be conducted post-construction, and movements of Motus-tagged ESA-listed birds in the vicinity of the Lease Area will be monitored for at least three years post-construction, during the spring, summer, and fall. Motus receivers will be installed within the Lease Area to determine the presence/absence of ESA-listed species. The specific number and location of offshore receiver stations will be selected in accordance with current guidance documents, such as the *Draft Guidance for Pre- and Post-Construction Monitoring to Detect Changes in Marine Bird Distributions and Habitat Use Related to Offshore Wind Development*. SouthCoast Wind will work with USFWS to determine appropriate funding and support to be provided to researchers working with ESA-listed birds.

ESA-listed bird presence/absence in the Lease Area will be analyzed by comparing detections within the Lease Area to coastal receiver towers. All detections can be analyzed to understand relationships with time of day, season, and weather.

5. Radar Monitoring: Nocturnal Migrants

Nocturnal migrants, including songbirds and shorebirds, are documented to fly offshore (Adams et al. 2015, Loring et al. 2021). Breeding songbirds that occur in the region are mostly neotropical migrants, flying north to south along the U.S. Atlantic Coast to the tropical regions of Mexico, the Caribbean, and Central and South America. During migration, songbirds mostly travel at night at high altitudes and regularly cross large bodies of water, including the Mediterranean Sea and the Gulf of Mexico (Bruderer & Lietchi, 1999; Gauthreaux & Belser, 1999). Various songbird species may traverse the Lease Area during migration periods. During migration, most songbirds fly at altitudes between 295 to 1,969 ft (90 and 600 m) (NYSERDA, 2015), with a large proportion of migratory movements occurring above the rotor swept zone (RSZ) of most offshore WTGs. However, flight heights vary according to species and conditions. For shorebird species, evidence suggests that many species migrate at flight heights over 2,000 feet (610 m), which are above the RSZ of most offshore WTGs (approximately 837 ft [255 m]) as described in Senner et al. (2018) and Green (2004). It is therefore expected that shorebird occurrence in the Lease Area for most species is possible but is expected to be uncommon and limited to spring and fall migration periods.

Since nocturnal migration events are episodic and cannot be detected during daytime surveys, there is uncertainty on the timing and intensity of migration offshore. Similar to other MA/RI WEA offshore wind projects, SouthCoast Wind will monitor nocturnal migrants with 3D radar for up to two years post-construction to record the passage rates (flux) of migrants and their flight heights. Specific radar system(s), location, time of year, and methodology will be determined in consultation with USFWS closer to the commencement of Project operations. The results of such radar monitoring could be related to time of year and weather conditions, to increase the understanding on when nocturnal migrants may have higher collision risk.

6. Radar Monitoring: Marine Bird Avoidance

Some marine birds, including loons and sea ducks, have been shown to exhibit avoidance of offshore wind farms (Furness et al., 2013). Loons are among the species identified as most vulnerable to displacement (Heinänen et al., 2020; Furness et al., 2013; Garthe & Hüppop, 2004). Sea ducks are also vulnerable to displacement. Avoidance behavior has been documented for several species, including black scoter and common eider (Desholm & Kahlert, 2005, Larsen & Guillemette, 2007) and studies have also documented sea ducks increasing their altitude to avoid WTGs at night (Desholm & Kahlert, 2005). SouthCoast Wind is considering conducting up to 2 years of radar study to collect data on macro (and potentially meso) avoidance rates. The radar would run continuously to collect data at times when birds vulnerable to displacement are present. These data on macro-avoidance would support understanding of both displacement and collision vulnerability.

7. Documentation of Dead and Injured Birds and Bats

Several factors influence the risk of collision with offshore wind project components for birds, including behavior, season, weather, and lighting. In general, species using marine habitats have exhibited lower collision rates than those documented at terrestrial wind facilities, although data from offshore operational sites are very limited (Adams et al., 2017; Thaxter et al., 2017). SouthCoast Wind will implement a reporting system to document dead or injured birds or bats found incidentally on vessels and offshore Project structures during construction, operation, and decommissioning. The location will be marked using GPS, an Incident Reporting Form will be filled out, and digital photographs will be taken. Any animals detected that could be ESA-listed will have their identity confirmed by consulting biologists, and a report will be submitted to the designated staff at SouthCoast Wind who will then report it to BOEM, USFWS, and other relevant regulatory agencies. Carcasses with federal or research bands or tags will be reported to the U.S. Geological Survey (USGS) Bird Band Laboratory at https://www.pwrc.usgs.gov/bbl/.

8. Adaptive Monitoring and Management

Over the course of monitoring, SouthCoast Wind will work with BOEM, USFWS, MassWildlife, RIDEM, and other relevant regulatory agencies to determine the need for adjustments to monitoring approaches, consideration of new monitoring technologies, and/or additional periods of monitoring based on an ongoing assessment of monitoring results. Potential triggers for adaptive monitoring may include, but are not limited to, equipment failure, an unexpected impact to birds or bats identified through monitoring, or new opportunities to collaborate with other projects in the region. The Monitoring Plan will include a series of potential adaptive monitoring actions, developed in coordination with BOEM, USFWS, and other relevant regulatory agencies. In addition to Adaptive Monitoring, SouthCoast Wind will use an Adaptive Management approach in which ongoing bird and bat data collection in offshore wind lease areas will be used to inform Project operations and conservation mitigation strategies, as available and applicable. This should result in reductions of direct and indirect impacts of operations throughout the lifetime of the Project.

9. Reporting

SouthCoast Wind will submit an annual Monitoring Report to BOEM summarizing post-construction monitoring activities, preliminary results as available, and any proposed changes in the monitoring program. SouthCoast Wind will consult with BOEM and USFWS, as necessary, to discuss the report and adaptive changes to the Monitoring Plan.

Appendix H: Seascape, Landscape, and Visual Impact Assessment

H.1 Introduction

This appendix describes the Seascape, Landscape, and Visual Impact Assessment (SLVIA) methodology and key findings that the Bureau of Ocean Energy Management (BOEM) used to identify the potential impacts of offshore wind structures (wind turbine generators [WTGs] and offshore substation platforms [OSPs]) on scenic and visual resources in the geographic analysis area. This SLVIA methodology applies to any offshore wind energy development proposed for the Outer Continental Shelf (OCS) and incorporates by reference the detailed description of the methodology described in the *Assessment of Seascape, Landscape, and Visual Impacts of Offshore Wind Energy Developments on the Outer Continental Shelf of the United States* (BOEM 2021). Section H.2, *Method of Analysis*, describes the specific methodology used to apply the SLVIA methodology to the SouthCoast Wind Construction and Operations Plan (COP) (SouthCoast Wind 2024) and Section H.3, *Results,* summarizes the wind farm distances, fields of view (FOVs), noticeable elements, visual contrasts, scale of change, and prominence that contributed to the determination of impact levels for each key observation point (KOP) under the Proposed Action and each of the action alternatives that include modifications to WTG array layouts. Maps of scenic resources present in the geographic analysis area are included in Section 3.6.9, *Scenic and Visual Resources*. Visual simulations of the Proposed Action alone, other ongoing and planned offshore wind projects without the Proposed Action, and other offshore wind projects in combination with the Proposed Action are included in Attachment H-1, *Cumulative Visual Simulations*.

H.2 Method of Analysis

The SLVIA has two separate but linked parts: the seascape, open ocean, and landscape impact assessment (SLIA) and visual impact analysis (VIA). The SLIA analyzes and evaluates sensitivity, susceptibility, and magnitude of change in consideration of impacts on both the physical elements and features that make up a landscape, seascape, or open ocean; and the aesthetic, perceptual, and experiential aspects of the landscape, seascape, or open ocean that make it distinctive. These impacts affect the “feel,” “character,” or “sense of place” of an area of landscape, seascape, or open ocean, rather than the composition of a view from a particular place. In the SLIA, the impact receptors (the entities that are potentially affected by the proposed Project) are the seascape/open ocean/landscape itself and its components, both its physical features and its distinctive character.

The VIA analyzes and evaluates the impacts on people of adding the proposed development to views from selected viewpoints. The VIA evaluates the change to the composition of the view itself and assesses how the people who are likely to be at that viewpoint may be affected by the change to the view. Enjoyment of a particular view is dependent on the viewer and, in the VIA, the impact receptors are people. The inclusion of both the SLIA and VIA in the BOEM SLVIA methodology is consistent with the National Environmental Policy Act (NEPA)’s objective of providing Americans with aesthetically and culturally pleasing surroundings and its requirement to consider all potentially significant impacts of development.

The magnitude of effect in a seascape, open ocean, landscape, or view depends on the nature, scale, prominence, and visual contrast of the change and its experiential duration. The SLVIA offshore geographic analysis area consists of the earth curvature-based extent of the zone of theoretical visibility and zones of visual influence (COP Appendix T; SouthCoast Wind 2024), as follows.

- The offshore turbine array area where the WTGs and OSP would be located plus a 42.8-mile (68.9-kilometer) radius area. This distance is the maximum extent within which a seascape, open ocean, landscape, or visual effect could occur, given visibility of the maximum height of the WTG rotor (1,066 feet [324.9 meters]).
- The OSP (maximum height of 344.5 feet [105 meters]) would potentially be visible to a distance of 25.5 miles (41.0 kilometers).

WTG visibility would be variable through the day depending on many factors. View angle, sun angle, and atmospheric conditions would affect the WTG visibility. Visual contrast of WTGs would vary throughout the day depending on the visual character of the horizon's backdrop and whether the WTGs are backlit, side-lit, or front-lit. If less visual contrast is apparent in the morning hours, then it is likely that the visual contrast may be more pronounced in the afternoon. The inverse is possible, as well. These effects are also influenced by varying atmospheric conditions, direction of view, distance between the viewer and the WTGs, and elevation of the viewer.

At closer distances, approximately 12 miles or closer, the form of the WTG may be the dominant visual element creating the visual contrast regardless of color. At greater distances, color may become the dominant visual element creating visual contrast under certain visual conditions that gives visual definition to the WTG's form and line.

As the elevation of the viewer increases, the lesser the effect Earth curvature (EC) has on the visible height of individual WTGs.

While the shoreline has a prevailing southward viewing direction, localized views may vary from southeast to west. All cardinal directions are conceivable when viewing from a lighthouse or a water vessel at sea. When viewing from onshore toward a southerly direction and scanning to the east and west, the color of the horizon backdrop often will vary. Variation will continue as the sun arcs across the sky from sunrise to sunset. Depending on sun angle, the backdrop sky color may have various intensities of white to gray and sky blue to pale blue to dark blue-gray. Partly cloudy to overcast conditions will also influence the color make-up of the horizon's backdrop. The sunrise and sunset have varying degrees of light blue to dark blue, light and dark purples intermixed with oranges, yellows, and reds. Partly cloudy skies may increase the remarkable color effects during the sunset and sunrise periods of the day.

When placing WTGs offshore, the visual interplay and contrasting elements in form, line, color, and texture may vary with the ever-changing character of the backdrop. Front-lit WTGs may have strong color contrast against a darker gray sky, giving definition to the WTG's vertical form and line contrast to the ocean's horizontal character and the line where the sea meets sky, or visually dissipates against a whiter backdrop created by high levels of evaporative atmospheric moisture during clear sunny days. Partly cloudy skies may create varying degrees of sunlight reflecting off the white wind turbines, placing some WTGs in the shadow and making them appear a darker gray and less conspicuous while highlighting others with a bright white color contrast. The level of noticeability would be directly proportional to the degree of visual contrast and scale of change between the WTGs and the corresponding backdrop.

These variations through the course of the day may result in periods of moderate to major visual effects while at other times of day would have minor or negligible effects.

The onshore geographic analysis area includes landfalls, buried onshore export cables, an onshore substation and up to two converter stations, and transmission connections to the electric grid. The visual impacts of onshore components are assessed in Chapter 3, Section 3.6.9, *Scenic and Visual Resources*.

The SLVIA methodology and parameters consider local stakeholders' identity, culture, values, and issues and the understanding of baseline maritime conditions. Project activities for all stages of the Project life cycle (construction and installation, operations and maintenance [O&M], and decommissioning) are assessed against the environmental baseline to identify the potential interactions between the Project and the seascape, landscape, and viewers. Potential impacts are assessed to determine an impact level consistent with the definitions in Table H-1.

Table H-1. Definitions of potential adverse impact levels

Impact Level	Historic Properties under Section 106 of the NHPA	Visual Resources
Negligible	Adverse	SLIA: Very little or no effect on seascape/landscape unit character, features, elements, or key qualities either because unit lacks distinctive character, features, elements, or key qualities; values for these are low; or Project visibility is minimal. VIA: Very little or no effect on viewers' experiences because Project visibility/contrast/magnitude of change is minimal, or view receptor sensitivity/susceptibility/value is minimal.
Minor	Adverse	SLIA: The Project would introduce features that may have low to medium levels of visual prominence in the geographic area of an ocean/seascape/landscape character unit. The Project features may introduce a visual character that is somewhat inconsistent with the character of the unit, which may have minor to medium negative effects on the unit's features, elements, or key qualities, but the unit's features, elements, or key qualities have low susceptibility or value. VIA: The visibility of the Project would introduce a small but noticeable to medium level of change to the view's character; have a low to medium level of visual prominence that attracts but may or may not hold the viewer's attention; and have a small to medium effect on the viewer's experience. The viewer receptor sensitivity/susceptibility/value is low. If the value, susceptibility, and viewer concern for change is medium or high, then evaluate

Impact Level	Historic Properties under Section 106 of the NHPA	Visual Resources
		the nature of the sensitivity to determine if elevating the impact to the next level is justified. For instance, a KOP with a low magnitude of change, but a high level of viewer concern (combination of susceptibility/value), may justify adjusting to a moderate level of impact.
Moderate	Adverse	SLIA: The Project would introduce features that would have medium to large levels of visual prominence within the geographic area of an ocean/seascape/landscape character unit. The Project would introduce a visual character that is inconsistent with the character of the unit, which may have a moderate negative effect on the unit's features, elements, or the key qualities. In areas affected by large magnitudes of change, the unit's features, elements or key qualities have low susceptibility or value. VIA: The visibility of the Project would introduce a moderate to large level of change to the view's character; may have a moderate to large level of visual prominence that attracts and holds, but may or may not dominate the viewer's attention; and has a moderate effect on the viewer's visual experience. The viewer receptor sensitivity/susceptibility/value is medium to low. Moderate impacts are typically associated with medium viewer receptor sensitivity (combination of susceptibility/value) in areas where the view's character has medium levels of change; or low viewer receptor sensitivity (combination of susceptibility/value) in areas where the view's character has large changes to the character. If the value, susceptibility, and viewer concern for change is high, then evaluate the nature of the sensitivity to determine if elevating the impact to the next level is justified.
Major	Adverse	SLIA: The Project would introduce features that would have dominant levels of visual prominence in the geographic area of an ocean/seascape/landscape character unit. The Project would introduce a visual character that is inconsistent with the character of the unit, which may have a major negative effect on the unit's features, elements, or key qualities. The concern for change (combination of susceptibility/value) to the character unit is high. VIA: The visibility of the Project would introduce a major level of character change to the view; would attract, hold, and dominate the viewer's attention; and would have a moderate to major effect on the viewer's visual experience. The viewer receptor sensitivity/susceptibility/value is medium to high. If the magnitude of change to the view's character is medium, but the susceptibility or value at the KOP is high, then evaluate the nature of the sensitivity to determine if elevating the impact to major is justified. If the sensitivity (combination of susceptibility/value) at the KOP is low in an area where the magnitude of change is large, then evaluate the nature of the sensitivity to determine if lowering the impact to moderate is justified.

H.3 Results

H.3.1 Proposed Action

Atmospheric conditions offshore and near the shoreline limit views more than the typically drier-air conditions in inland areas. Visual simulations from representative viewpoints included as Attachment 3 to the *SouthCoast Wind Visual Impact Assessment Report* (COP Appendix T; SouthCoast Wind 2024) indicate that daytime and nighttime visibility of WTGs and OSPs would be noticeable to the casual observer from seascape character areas, the open ocean character area, landscape character areas, and viewer viewpoints. Based on COP VIA Appendix T, Table 5-5 (SouthCoast Wind 2024), acreages of character areas overall in the offshore geographic analysis area and within the offshore wind farm viewshed are listed in Table H-2. Applicable effects from the Proposed Action and alternatives on seascape character units, the open ocean character unit, and landscape character units are listed throughout this appendix.

Table H-2. Area of landscape/seascape and ocean character types within the Offshore Project area viewsheds

Landcover/Open Ocean	Acres (hectares) of Landscape/ Seascape and Ocean Character Type	Acres (hectares) within Area of Potential Visual Impact	Percentage of Landscape/Seascape Character Type in Area of Potential Visual Impact

Source: COP Appendix T, Table 5-5; SouthCoast Wind 2024

Distances from beach KOPs to the Proposed Action WTG and OSP array would range from the following.

- 37.2 miles (59.9 kilometers) from KOP-16-MV Squibnocket Beach on the western extent of the geographic analysis area.
- 23.3 miles (37.5 kilometers) from KOP-11-N Miacomet Beach, which is the closest KOP to the front edge of the WTG array,
- 26.5 miles (42.6 kilometers) from KOP-6-N Tom Nevers Beach on the eastern extent of the geographic analysis area.

The noticeable daytime and nighttime elements of the Project's WTGs and OSP and their viewshed distances are listed in Table H-3. Each WTG would have two L-864 flashing-red obstruction lights on the top of the nacelle, one of which is required to be lit (BOEM 2021). WTGs would have additional intermediate lighting on the tower utilizing low-intensity red-flashing (L-810) obstruction lighting. Line-of-sight calculations for onshore viewers (5.9-foot [1.8-meter] eye level) are based on intervening EC screening (7.98 inches [20.3 centimeters] height per mile). Heights of WTG and substation components are stated relative to mean lower low water (MLLW) and highest astronomical tide.

Atmospheric refraction of light rays causes fluctuations in the extents and appearances of offshore and onshore facilities. It results from the bending of light rays between viewers and objects due to current air temperature, water vapor, and barometric pressure (Bislins 2022). Based on the average sea level refraction calculation coefficient of 0.17 (Bislins 2022) applied to the turbine blade tip viewshed distance of 42.8 miles (68.9 kilometers), the 1,066.3-foot (325.0-meter) turbines may be projected upward to increased visibility from 0.0 feet (0.0 meters) to 192 feet (58.5 meters) above the horizon. The nearest beach viewers, located at 23.3 miles (37.5 kilometers) from the Lease Area, may see increased visibility of the 1,066.3-foot (325.0-meter) turbines from 790 feet (240.8 meters) to 844 feet (257.3 meters) above the horizon. Variability of daytime and nighttime atmospheric refraction-based visibility occurs with sea level's continuous increases and decreases in temperature, water vapor, and barometric pressure.

Table H-4 and Table H-5 indicate the Proposed Action's effects based on horizontal FOV and vertical FOV, respectively, defined as the earth curvature-based extent of the observable landscape seen at any given moment, usually measured in degrees (BOEM 2021). The horizontal FOV for each KOP is listed in COP Appendix T (SouthCoast Wind 2024). FOVs are valid and reliable indicators of the magnitude of view occupation by Proposed Action facilities. Typical human perception extends to 124° in the horizontal axis and 55° in the vertical axis. The nearest shoreline viewers would be 23.3 miles (37.5 kilometers) from the Wind Farm Area. EC, at this distance, reduces the observable height above the horizon of the nearest WTG from 1,066 feet (324.9 meters) MLLW to 788 feet (244 meters), resulting in occupation of 0.4° and 0.7 percent of the vertical view. WTGs would further diminish in perceived size with distance and EC.

Table H-3. Heights of noticeable [a] WTG elements and substations and visible distances [b]

Noticeable Element	Height in Feet (meters)	Visible Distance [b] in Miles (kilometers)
Rotor Blade Tip	1,066.3 (325.0) MLLW	0–42.8 (68.9)
Aviation Light	624 (190.2) MLLW	0–33.5 (53.9)
Nacelle	614 (187.1) MLLW	0–33.3 (53.6)
Hub	605.1 (184.4) MLLW	0–30.0 (48.3)
OSP	344.5 (105) MLLW	0–25.5 (41.0)
Mid-tower Light	302 (92) MLLW	0–24.2 (38.9)
Yellow Tower Base Color	50 (15) HAT	0–11.4 (18.3)

[a] Perception of Project elements, from 5.5 feet (1.7 meters) human eye level while standing at mean sea level, involves static distance-related sizes, forms, lines, colors, and textures; variable daytime lighting conditions; variable nighttime light conditions; and variable meteorological conditions.
[b] Based on intervening EC and clear-day conditions.
HAT = highest astronomical tide

Table H-4. Horizontal FOV occupied by the Proposed Action

Noticeable Element	Width miles (kilometers)	Distance miles (kilometers)	Horizontal FOV	Human FOV	Percent of FOV
Wind Farm	9.8 (15.8)	23.3 (37.5)	22.8°	124°	18%

Table H-5. Vertical FOV occupied by the Proposed Action

Noticeable Element	Height feet (meters)	Distance miles (kilometers)	Height Above Horizon [a] feet (meters)	Vertical FOV	Human FOV	Percent of FOV
Rotor Blade Tip	1,066 feet (324.9) MLLW	23.3 (37.5)	788 (244)	0.4°	55°	0.7%

[a] Based on intervening EC and clear-day conditions.

Table H-6 lists the wind farm's distances, horizontal FOVs, noticeable features based on their heights and EC, and visual contrasts. The analysis considers the introduction of WTGs and OSP to an open ocean baseline. The scale, size, contrast, and prominence of change focuses on the following.

- Arrangement of WTGs and OSP in the view.
- Horizontal FOV and vertical FOV scale of the wind farm array, based on WTG and OSP size and number.
- Position of the array in the open ocean.
- Position of the array in the view.
- Turbine array's distance from the viewer.

Visibility, character-changing effects, and visual contrasts reduce steadily with distance from the observation point. Visibility, character-changing effects, scale, prominence, and visual contrasts increase with elevated observer position in comparison with the wind farm. Distance and observer elevation considerations are informed by the VIA simulations (COP Appendix T; SouthCoast Wind 2024), EC calculations, horizontal FOV, and vertical FOV in undeveloped open ocean. The wind farm and nearest WTGs would be:

- Unavoidably dominant features in the offshore view between 0 and 5 miles (0–8 kilometers) distance.
- Strongly pervasive features in the onshore to offshore view between 5 and 12 miles (8–19.3 kilometers) distance.
- Clearly visible features in the onshore to offshore view between 12 and 28 miles (19.3–45.1 kilometers) distance.
- Low on the horizon, but persistent features in the onshore to offshore view between 28 and 31 miles (45.1–49.9 kilometers) distance.
- Intermittently noticed features in the onshore to offshore view between 31 and 42.8 miles (49.9–68.9 kilometers) distance.
- Below the horizon beyond 42.8 miles (68.9 kilometers) distance.

Visual contrast determinations involve comparisons of characteristics of the seascape, open ocean, and landscape before and after Project implementation. The range of potential contrasts includes strong, moderate, weak, and none (BOEM 2021). The strongest daytime contrasts would result from tranquil and flat seas combined with sunlit WTG towers, nacelles, flickering rotors, and a yellow tower base color against a dark background sky and an undifferentiated foreground. There would be daily variation in WTG color contrast as sun angles change from back-lit to front-lit (sunrise to sunset) and the backdrop would vary under different lighting and atmospheric conditions. The weakest daytime contrasts would result from turbulent seas combined with overcast daylight conditions on WTG towers, nacelles, and rotors against an overcast background sky and a foreground modulated by varied landscape elements. The strongest nighttime contrasts would result from dark skies (absent moonlight) combined with aviation lights, activated lighting on the OSP, mid-tower lights, and Project lighting reflections on low clouds and active (non-reflective) surf, and the dark-sky light dome. The weakest nighttime contrasts would result from moonlit, cloudless skies; tranquil (reflective) seas; Aircraft Detection Lighting System (ADLS) activation; and only mid-tower lights.

The seascape character units, open ocean character unit, landscape character units, and viewer experiences would be affected by the Proposed Action's noticeable features; applicable distances and FOV extents; open views versus view framing and intervening foregrounds; form, line, color, and texture contrasts; scale of change; and prominence in the characteristic seascape and landscape. Higher impact levels would stem from unique, extensive, and long-term appearance of strongly contrasting, large, and prominent vertical structures in the otherwise horizontal seascape environment, where structures are an unexpected element and viewer experience is of formerly open views of high-sensitivity seascape, open ocean, and landscape and from high sensitivity view receptors.

[e] BP – Brayton Point

[f] C= Cape Cod

[g] Noticeable elements: R = rotor, AL = aviation light, N = nacelle, H = hub, O = OSP, M = mid-tower light, Y = yellow tower base color

[h] WTGs and OSP visibility: 0 = Not visible. 1 = Visible only after extended study; otherwise not visible. 2 = Visible when viewing in general direction of the wind farm; otherwise likely to be missed by casual observer. 3 = Visible after brief glance in general direction of the wind farm; unlikely to be missed by casual observer. 4 = Plainly visible; could not be missed by casual observer, but does not strongly attract visual attention or dominate view. 5 = Strongly attracts viewers' attention to the wind farm; moderate to strong contrasts in form, line, color, or texture, luminance, or motion. 6 = Dominates view; strong contrasts in form, line, color, texture, luminance, or motion fill most of the horizontal FOV or vertical FOV (NAEP 2012).

[i] Elevated lighthouse viewpoint

This page intentionally left blank

Construction involving moving and stationary visual feature contrasts to forms, lines, colors, textures, scale, and prominence in formerly open ocean may have more effect on viewers than operational and decommissioning impacts, where the viewing context is existing WTGs and substations. Construction impacts would be temporary and would include the following.

- Daytime and nighttime movement of installation vessels, cranes, and other equipment visible in the open ocean in and around the Lease Area.
- Dawn, dusk, and nighttime construction lighting on WTGs and OSP.
- Beach, other sensitive land-based, and boat and cruise ship views of WTGs and OSP under construction.
- Laying of the offshore and onshore buried export cables and the connections between offshore and onshore export cables at landing sites.
- Activities along the onshore landfalls, export cable routes, and Brayton Point and Falmouth onshore converter station and substation sites.

Operational effects would be similar to those of end-stage construction and would be long term and fully reversible.

Proposed Action impacts on high-sensitivity open ocean character would be **major**. The daytime and nighttime (lighting) presence of the WTGs, OSP, and construction and O&M vessel traffic would change perception of this area from natural, undeveloped open ocean to a developed wind energy environment characterized by visually dominant WTGs and OSP.

Maintenance activities would cause **minor** effects on open ocean character by increased O&M vessel traffic to and from the Wind Farm Area. Increases in these vessel movements would be noticeable to offshore viewers but are unlikely to have a significant effect.

Decommissioning would involve the removal of all offshore structures and is expected to follow the reverse of the construction activity. Decommissioning activities would cause effects similar to those of construction activities.

Daytime lighting of WTGs is not required. ADLS would reduce nighttime impact levels from **major** or **moderate** to **negligible**, due to substantially limited hours of lighting. Residual impacts would result from the presence of continuously flashing lights, a sky light dome, and reflections on clouds during those limited hours. Lights of the up to five OSPs, when lit for maintenance, potentially would be visible from beaches and adjoining land and the built environment during hours of darkness. The nighttime sky light dome and cloud lighting caused by reflections from the water surface may be seen from distances beyond the 42.8-mile (68.9-kilometer) geographic analysis area, depending on variable ocean surface and meteorological reflectivity. The onshore substation and converter stations' nighttime lighting would be visible in their immediate neighborhoods during the hours of darkness and similar in magnitude and extent to existing conditions.

Table H-7 lists the Proposed Action's noticeable features based on their heights, distances, and EC.

Table H-7. Noticeable elements and impacts by seascape character unit, open ocean character unit, landscape character unit, and KOP for the Proposed Action

Noticeable Elements [a] Impacts	Seascape Units, Open Ocean Unit, Landscape Units, and Offshore and Onshore Key Observation Points

Onshore substation structures **Moderate**	KOP-49-C Two Ponds
Onshore substation structures **Negligible**	KOP-1-BP Brayton Point Beach KOP-3-BP Sycamore Street KOP-4-BP Route 103 at Anthony Bridge

[a] R = rotor, AL = aviation light, N = nacelle, H = hub, O = OSP, M = mid-tower light, Y = yellow tower base color
[b] Major impacts when ADLS is activated.
[c] Negligible impacts when ADLS is not activated.

Table H-8 summarizes the Proposed Action's noticeability based on distance and effects on the seascape units, open ocean unit, landscape units, and KOPs. Noticeability is based on the offshore wind turbine visibility work by Robert Sullivan (Sullivan et al. 2013).

Table H-8. Wind farm distance effects by seascape character unit, open ocean character unit, landscape character unit, and KOP for the Proposed Action

Distance in Miles (km) Effects	Seascape Units, Open Ocean Unit, Landscape Units, and Offshore and Onshore Key Observation Points
0–40.0 (0–64.4) Dominant/Major to Minor Noticeability	Open Ocean Character Unit KOP-1-O Recreational Fishing, Pleasure, and Tour Boat Area
5.0–40.0 (8.0–64.4) Dominant/Major to Minor Noticeability	Open Ocean Character Unit KOP-2-O Cruise Ship Shipping Lanes
23.5-25.6 (37.8-41.2) Dominant/Major Noticeability	KOP-8-N Tom Nevers Field-Nighttime KOP-12-N Cisco Beach-Nighttime
23.3–24.2 (37.5–38.9) Moderate Noticeability	Seascape Character Units: • Ocean • Sound • Beachfront • Coastal Bluff • Coastal Dune • Boardwalk • Coastal Scrub • Commercial • Forests/Woodlands • Institutional • Park • Preserve • Residential • Salt Pond • Transportation • Village/Town KOPs: KOP-8-N Tom Nevers Field-Daytime KOP-10-N Nobadeer Beach KOP-11-N Miacomet Beach and Pond KOP-12-N Cisco Beach-Daytime KOP-13-N Hummock Pond Road Bike Path KOP-16-N Head of Plains KOP-17-N Bartlett's Farm KOP-18-N Ladies Beach KOP-20-N Madequecham 1 KOP-22-N Madaket Beach at Sunset

Distance in Miles (km) Effects	Seascape Units, Open Ocean Unit, Landscape Units, and Offshore and Onshore Key Observation Points
24.3–33.6 (39.1–54.1) Minor Noticeability	Seascape Character Units: • Ocean • Sound • Beachfront • Coastal Bluff • Coastal Dune • Boardwalk • Coastal Scrub • Commercial • Forests/Woodlands • Institutional • Park • Preserve • Residential • Salt Pond • Transportation • Village/Town Landscape Character Units: • Agriculture • Coastal Scrub • Commercial • Estuary • Forests/Woodlands • Institutional • Light Industrial • Marshland • Park • Preserve • Residential • Salt Pond • Pond Shoreline • Transportation • Village/Town KOPs: KOP-1-MV Wasque Point KOP-2-MV Wasque Point Reservation KOP-3-MV Wasque Avenue KOP-4-MV South Beach KOP-6-MV Long Point Beach KOP-9-MV 322 South Road KOP-16-MV Squibnocket Beach KOP-2-N Sanford Farm Barn Overlook KOP-3-N Madaket Beach KOP-6-N Tom Nevers Beach KOP-8-N Tom Nevers Field-Daytime
29.4-41.2 (47.3-66.3) Minor Noticeability	KOP-21-N Sankaty Head Lighthouse (elevated viewpoint) KOP-19-MV Gay Head Lighthouse (elevated viewpoint)

Distance in Miles (km) Effects	Seascape Units, Open Ocean Unit, Landscape Units, and Offshore and Onshore Key Observation Points
31.1–42.8 (50.1–68.9) Minor to Negligible Noticeability	Landscape Character Units: • Agriculture • Coastal Scrub • Commercial • Estuary • Forests/Woodlands • Institutional • Light Industrial • Marshland • Park • Preserve • Residential • Salt Pond • Pond Shoreline • Transportation • Village/Town

km = kilometers

Table H-9 summarizes the Proposed Action's wind farm percent of FOV occupied by the wind farm, and effects on the seascape units, landscape units, and KOPs' viewer experience. FOV measures consider size, horizontal extent, and vertical extent of the facilities and indicate the scale of impact in comparison with the typical 124-degree human view cone. The WTG array's configuration results in narrower angles and shorter distances from Nantucket and wider angles from Martha's Vineyard's greater distances. Thus, moderate to minor effects involve both distance's noticeable elements and FOV measures.

Table H-9. Wind farm percent of FOV and effects by seascape character unit, open ocean character unit, landscape character unit, and KOP for the Proposed Action

Percent (°) of 124° FOV POV [a] Effects [b]	Seascape Units, Open Ocean Unit, Landscape Units, and Offshore and Onshore Key Observation Points
100% (124°) to 16% (20°) Dominant/Major to Minor	Open Ocean Character Unit KOP-1-O Recreational Fishing, Pleasure, and Tour Boat Area KOP-2-O Cruise Ship Shipping Lanes
21% (26°) to 17% (19°) Moderate	Seascape Character Units: • Ocean • Sound • Beachfront • Coastal Bluff • Coastal Dune • Boardwalk • Coastal Scrub • Commercial • Forests/Woodlands • Institutional • Park • Preserve • Residential

Percent (°) of 124° FOV POV [a] Effects [b]	Seascape Units, Open Ocean Unit, Landscape Units, and Offshore and Onshore Key Observation Points
	• Salt Pond • Transportation • Village/Town Landscape Character Units: • Agriculture • Coastal Scrub • Commercial • Estuary • Forests/Woodlands • Institutional • Light Industrial • Marshland • Park • Preserve • Residential • Salt Pond • Pond Shoreline • Transportation • Village/Town KOP-8-N Tom Nevers Field-Daytime KOP-10-N Nobadeer Beach KOP-11-N Miacomet Beach and Pond KOP-12-N Cisco Beach-Daytime KOP-13-N Hummock Pond Road Bike Path KOP-16-N Head of Plains KOP-17-N Bartlett's Farm KOP-18-N Ladies Beach KOP-20-N Madequecham 1 KOP-22-N Madaket Beach at Sunset
26% (32°) to 14% (17°) Minor to Moderate	Seascape Character Units: • Ocean • Sound • Beachfront • Coastal Bluff • Coastal Dune • Boardwalk • Coastal Scrub • Commercial • Forests/Woodlands • Institutional • Park • Preserve • Residential • Salt Pond • Transportation • Village/Town Landscape Character Units: • Agriculture

Percent (°) of 124° FOV POV [a] Effects [b]	Seascape Units, Open Ocean Unit, Landscape Units, and Offshore and Onshore Key Observation Points
	• Coastal Scrub • Commercial • Estuary • Forests/Woodlands • Institutional • Light Industrial • Marshland • Park • Preserve • Residential • Salt Pond • Pond Shoreline • Transportation • Village/Town KOP-1-MV Wasque Point KOP-2-MV Wasque Point Reservation KOP-3-MV Wasque Avenue KOP-4-MV South Beach KOP-6-MV Long Point Beach KOP-9-MV 322 South Road KOP-16-MV Squibnocket Beach KOP-19-MV Gay Head Lighthouse (elevated viewpoint) KOP-2-N Sanford Farm Barn Overlook KOP-3-N Madaket Beach KOP-6-N Tom Nevers Beach KOP-21-N Sankaty Head Lighthouse (elevated viewpoint)

[a] Percent of view
[b] Wind farm array configuration results in narrower angles from Nantucket and wider angles from Martha's Vineyard's greater distances. Thus, overall moderate to minor effects involve distance and noticeable elements.

Foreground influence assessments, involving the presence of intervening or framing elements and their influence on effects of Project characteristics, are based on each KOP's locale photography and visual simulations (Attachment 3 of Appendix T; SouthCoast Wind 2024) and summarized in Table H-10.

Table H-10. Foreground view framing and intervening elements for the Proposed Action

Foreground Element(s) Influence	Seascape Units, Open Ocean Unit, Landscape Units, and Offshore and Onshore Key Observation Points
Open Ocean Negligible Influence	Open Ocean Character Unit KOP-1-O Recreational Fishing, Pleasure, and Tour Boat Area KOP-2-O Cruise Ship Shipping Lanes
Beach, Dunes, and Ocean Minor Influence	Seascape Character Units: • Ocean • Sound • Beachfront • Coastal Bluff • Coastal Dune • Boardwalk • Coastal Scrub • Commercial • Forests/Woodlands • Institutional • Park • Preserve • Residential • Salt Pond • Transportation • Village/Town KOP-1-MV Wasque Point KOP-4-MV South Beach KOP-6-MV Long Point Beach KOP-16-MV Squibnocket Beach KOP-6-N Tom Nevers Beach KOP-10-N Nobadeer Beach KOP-11-N Miacomet Beach and Pond KOP-12-N Cisco Beach-Daytime KOP-18-N Ladies Beach KOP-20-N Madequecham 1 KOP-22-N Madaket Beach at Sunset
Buildings, Vegetation, and Topography Moderate to Dominant Influence	Landscape Character Units: • Agriculture • Coastal Scrub • Commercial • Estuary • Forests/Woodlands • Institutional • Light Industrial • Marshland • Park • Preserve • Residential • Salt Pond • Pond Shoreline • Transportation • Village/Town

Foreground Element(s) Influence	Seascape Units, Open Ocean Unit, Landscape Units, and Offshore and Onshore Key Observation Points
	KOP-2-N Sanford Farm Barn Overlook KOP-3-N Madaket Beach

Proposed Action contrasts in the characteristic seascape and landscape, as perceived in views from each KOP, are based on visual simulations (COP Appendix T, Attachment 3; SouthCoast Wind 2024). Seascape unit view contrasts are estimated based on similar open view conditions in ocean environments. Landscape and seascape compatibility and photography conditions for each viewpoint are presented in COP Appendix T, Table 5-6 and Table 5-7, and Attachment T.1, Table 3-1 (SouthCoast Wind 2024). The COP landscape and seascape evaluation-scale ranges from faint, apparent, conspicuous, and prominent to dominant. Onshore viewpoints Oak Grove Cemetery, Goodwill Park, and Lawrence Lynch site road would result in prominent and dominant conditions. Offshore potential viewpoints' evaluations range from faint to dominant. Visual contrast determinations involve comparisons of characteristics of the seascape and landscape before and after Proposed Action implementation. The range of potential contrasts includes strong, moderate, weak, and none. The strongest daytime contrasts would result from tranquil and flat seas combined with sunlit WTG towers, nacelles, flickering rotors, and the yellow tower base color against a dark background sky and an undifferentiated foreground. The weakest daytime contrasts would result from turbulent seas combined with overcast daylight conditions on WTG towers, nacelles, and rotors against an overcast background sky and a foreground modulated by varied landscape elements. The strongest nighttime contrasts would result from dark skies (absent moonlight) combined with aviation lights, activated lighting on the OSP mid-tower lights, and Project lighting reflections on low clouds and active (non-reflective) surf, and the dark-sky light dome. The weakest nighttime contrasts would result from moonlit, cloudless skies, tranquil (reflective) seas, ADLS activation, and only mid-tower lights.

Photographic comparisons of characteristics of the seascape's and landscape's existing conditions and Proposed Action implementation are included in COP Appendix T, Attachment 3 (SouthCoast Wind 2024) for each of the KOPs in the following summary tables. Visual contrast determinations are listed in Table H-11.

Table H-11. Visual contrasts to seascape, open ocean, landscape, and KOPs for the Proposed Action

Contrast Rating Effects	Seascape, Open Ocean, Landscape, and Offshore and Onshore Key Observation Points
Strong Contrasts **Major**	Open Ocean KOP-1-O Recreational Fishing, Pleasure, and Tour Boat Area KOP-2-O Cruise Ship Shipping Lanes
Strong Contrasts (Limited Timeframe) **Moderate**	KOP-8-N Tom Nevers Field-Nighttime (the limited timeframe due to ADLS results in downward rating from Major to Negligible) KOP-12-N Cisco Beach-Nighttime (the limited timeframe due to ADLS results in downward rating from Major to Negligible)
Moderate Contrasts **Moderate**	Seascapes and Landscapes within 28 miles (kilometers) in the Wind Farm Area viewshed KOP-3-N Madaket Beach

Contrast Rating Effects	Seascape, Open Ocean, Landscape, and Offshore and Onshore Key Observation Points
	KOP-6-N Tom Nevers Beach KOP-8-N Tom Nevers Field-Daytime KOP-10-N Nobadeer Beach KOP-11-N Miacomet Beach and Pond KOP-12-N Cisco Beach-Daytime KOP-13-N Hummock Pond Road Bike Path KOP-16-N Head of Plains KOP-17-N Bartlett's Farm KOP-18-N Ladies Beach KOP-20-N Madequecham 1 KOP-22-N Madaket Beach
Weak Contrasts **Minor**	Seascapes and Landscapes beyond 28 miles (kilometers) in the Wind Farm Area viewshed KOP-1-MV Wasque Point KOP-2-MV Wasque Point Reservation KOP-3-MV Wasque Avenue KOP-4-MV South Beach KOP-6-MV Long Point Beach KOP-9-MV 322 South Road KOP-16-MV Squibnocket Beach KOP-19-MV Gay Head Lighthouse (Elevated viewpoint) KOP-2-N Sanford Farm Barn Overlook KOP-21-N Sankaty Head Lighthouse (Elevated viewpoint)
None to very weak **Negligible**	Seascapes, Landscapes, and viewer locations not in the Wind Farm Development Area viewshed

Table H-12 summarizes sensitivity, susceptibility, and magnitude of change in consideration of Proposed Action impacts on the seascape character units, open ocean character unit, and landscape character units throughout the geographic analysis area. The seascape, open ocean, and landscape criteria listed in Table H-1 and consideration of the preceding assessments would result in impact levels for character units as shown in Table H-12.

Table H-12. Proposed Action impacts on seascape character, open ocean character, and landscape character

Level of Impact	Seascape Character Units, Open Ocean Character Unit, and Landscape Character Units
Major	SLIA: Open Ocean Character Unit
Moderate	SLIA: Seascape Character Units and Landscape Character Units within the viewshed and within 28 miles of WTGs
Minor	SLIA: Seascape Character Units and Landscape Character Units within the viewshed and beyond 28 miles of WTGs
Negligible	SLIA: Seascape Character Units and Landscape Character Units outside of the WTG viewshed

SLIA = seascape, open ocean, and landscape impact assessment

Table H-13 summarizes Proposed Action impacts on viewer experience (KOP locations) throughout the geographic analysis area. The viewer experience criteria listed in Table H-1 and consideration of the preceding assessments would result in impact levels for KOPs as shown in Table H-13.

Table H-13. Impact levels on viewer experience for the Proposed Action

Impact Level	Offshore and Onshore Key Observation Points
Major	VIA: KOP-1-O Recreational Fishing, Pleasure, and Tour Boat Area KOP-2-O Commercial and Cruise Ship Shipping Lanes KOP-8-N Tom Nevers Field-Nighttime [a] KOP-12-N Cisco Beach-Nighttime [a] KOP-44-C Oak Grove Cemetery KOP-46-C Goodwill Park KOP-47-C Lawrence Lynch Site
Moderate	VIA: KOP-8-N Tom Nevers Field-Daytime KOP-10-N Nobadeer Beach KOP-11-N Miacomet Beach and Pond KOP-12-N Cisco Beach-Daytime KOP-13-N Hummock Pond Road Bike Path KOP-16-N Head of Plains KOP-17-N Bartlett's Farm KOP-18-N Ladies Beach KOP-20-N Madequecham 1 KOP-22-N Madaket Beach at Sunset KOP-49-C Two Ponds
Minor	VIA: KOP-1-MV Wasque Point KOP-2-MV Wasque Point Reservation KOP-3-MV Wasque Avenue KOP-4-MV South Beach KOP-6-MV Long Point Beach KOP-9-MV 322 South Road KOP-16-MV Squibnocket Beach KOP-19-MV Gay Head Lighthouse (Elevated viewpoint) KOP-2-N Sanford Farm Barn Overlook KOP-3-N Madaket Beach KOP-6-N Tom Nevers Beach KOP-21-N Sankaty Head Lighthouse (Elevated viewpoint)
Negligible	KOP-8-N Tom Nevers Field-Nighttime [b] KOP-12-N Cisco Beach-Nighttime [b] KOP-1-BP Brayton Point Beach KOP-3-BP Sycamore Street KOP-4-BP Route 103 at Anthony Bridge

[a] Major impacts when ADLS is activated.
[b] Negligible impacts when ADLS is not activated.

H.3.1.1 Cumulative Impacts of the Proposed Action

NEPA requires consideration of other reasonably foreseeable activities in the Project's viewshed and the Project's incremental effects on seascape character, open ocean character, landscape character, and viewer experience. These effects include direct physical effects on the seascape, open ocean, and landscape or changes to the distinct character of the seascape, open ocean, and landscape.

Effects on seascape character, open ocean character, and landscape character can occur in the following conditions (SLVIA Chapter 8; BOEM 2021).

- Multi-project WTGs and OSPs visible within or from the open ocean character unit as overlapping or adjacent features and elements.
- Multi-project WTGs and OSPs visible from seascape character units as overlapping or adjacent features and elements.
- Multi-project WTGs and OSPs visible from landscape character units as overlapping or adjacent features and elements.

Effects on viewer experience can occur in the following conditions (SLVIA Chapter 8; BOEM 2021).

- Multi-project WTGs and OSPs visible as overlapping features and elements.
- Multi-project WTGs and OSPs visible as adjacent features and elements.
- Multi-project WTGs and OSPs visible as viewers move through the seascape, open ocean, and landscape.

Attachment H-1 portrays simulations of the incremental effects of the Project in the context of other offshore wind projects, from a total of eight KOPs: five KOPs on Nantucket Island; an additional nighttime simulation for one of these KOPs (Cisco Beach); and two KOPs on Martha's Vineyard.

The visual simulations portray five incremental construction scenarios, as follows.

- Scenario 1: 2023–2025 Project Construction (Vineyard Wind, South Fork Wind, Revolution Wind, Sunrise Wind and New England Wind).
- Scenario 2: SouthCoast Wind Project Construction with prior 2023–2025 Project Construction (from Scenario 1).
- Scenario 3: 2024–2030 Project Construction (New England Wind II, Vineyard Wind Northeast [formerly Liberty Wind], Beacon Wind and Bay State Wind) with prior 2023–2025 Project Construction (Vineyard Wind, South Fork Wind, Revolution Wind, Sunrise Wind and New England Wind) and SouthCoast Wind Project Construction.
- Scenario 4 (full buildout): 2023–2025 Project Construction (Vineyard Wind, South Fork Wind, Revolution Wind, Sunrise Wind and New England Wind) and 2024–2030 Project Construction (New England Wind II, Vineyard Wind Northeast [formerly Liberty Wind], Beacon Wind and Bay State Wind) without SouthCoast Wind Project Construction.

- Scenario 5: The Project without other foreseeable planned activities.

The number of offshore wind structures simulated in Attachment H-1 differs slightly from the number of structures assumed in Appendix D, *Planned Activities Scenario*. This is due to the timing of when these documents were developed and the assumptions used in developing the layouts for the simulations. While the number of structures in the individual lease areas vary, the total number of structures assumed across the Massachusetts and Rhode Island lease areas is very similar between the two documents, with Appendix D assuming development of 1,069 structures and the cumulative visual simulations assuming development of 1,063 structures, a difference of only six structures. The number of offshore structures identified in both documents are estimates of reasonably foreseeable offshore wind development and are subject to change as lessees submit COPs and refine their development plans. BOEM believes the simulations presented in Attachment H-1 provide a reasonable approximation of the scale of visual impacts that would occur from development of the Proposed Action in combination with other ongoing and planned offshore wind projects.

Consideration of effects of other wind farms on seascape character, open ocean character, and landscape character is listed in Table H-14.

Consideration of effects on viewer experience of other wind farms is listed in Table H-15.

Consideration of effects on seascape character, open ocean character, and landscape character of other wind farms in combination with the Proposed Action is listed in Table H-16.

Consideration of effects on viewer experience of other wind farms in combination with the Proposed Action is listed in Table H-17.

Martha's Vineyard Landscape [f]	15.2 (24.4)	29.4 (47.3)	45.8 (73.7)	23.1 (37.1)	22.1 (35.5)	17.0 (27.3)	12.4 (19.9)	19.4 (31.2)	134° (109%)	R, AL, N, H, O, and M **Major**	Strong	Strong	Strong	Strong	Large	6 to 0
Nantucket Seascape (Beaches) [b]	17.4 (28.0)	19.4 (31.2)	32.0 (51.5)	29.1 (46.8)	47.2 (76.0)	35.2 (56.6)	34.6 (55.7)	15.5 (24.9)	104° (84%)	R, AL, N, H, O, and M **Major**	Strong	Strong	Strong	Strong	Large to NA	6 to 0
Nantucket Landscape [f]	17.6 (28.3)	19.6 (31.5)	32.2 (51.8)	29.3 (47.1)	47.4 (76.3)	35.4 (56.9)	34.8 (56.0)	15.7 (25.2)	104° (84%)	R, AL, N, H, O, and M **Major**	Strong	Strong	Strong	Strong	Large to NA	6 to 0

[a] BSW = Bay State Wind, BW = Beacon Wind, VWN = Vineyard Wind Northeast, NEW = New England Wind, SFW = South Fork Wind, SW = Sunrise Wind, RW = Revolution Wind, and VW = Vineyard Wind
[b] The most conservative onshore case involves the seaward edge of the beach nearest the projects. The seascape unit edge is 3.45 miles (kilometers) offshore (Massachusetts jurisdictional boundary).
[c] Due to Earth's curvature and known WTG heights, those WTGs beyond 42.8 miles (68.9 kilometers) would not be visible from ground level plus 5.5 feet (1.7 meters).
[d] Noticeable elements: R = rotor, AL = aviation light, N = nacelle, H = hub, O = OSP, M = mid-tower light, Y = yellow tower base color.
[e] WTGs and OSP Prominence (visibility): 0 = Not visible. 1 = Visible only after extended study; otherwise not visible. 2 = Visible when viewing in general direction of the wind farm; otherwise likely to be missed by casual observer. 3 = Visible after brief glance in general direction of the wind farm; unlikely to be missed by casual observer. 4 = Plainly visible; could not be missed by casual observer, but does not strongly attract visual attention or dominate view. 5 = Strongly attracts viewers' attention to the wind farm; moderate to strong contrasts in form, line, color, or texture, luminance, or motion. 6 = Dominates view; strong contrasts in form, line, color, texture, luminance, or motion fill most of the horizontal FOV or vertical FOV (NAEP 2012).
[f] The seaward edge between landscape and seascape varies. The most conservative case is 0.2-mile (0.3-kilometer) landward distance from seaward beach edge.

[a] KOP-1-MV Wasque Point, KOP-2-N Sanford Barn Overlook, KOP-22-N Madaket Beach at Sunset, KOP-6-N Tom Nevers Beach, KOP-12-N Cisco Beach, KOP-16-MV Squibnocket Beach, KOP-16-N Head of Plains, and KOP-19-MV Gay Head Lighthouse.
[b] BSW = Bay State Wind, BW = Beacon Wind, VWN = Vineyard Wind Northeast, SC = SouthCoast Wind, NEW = New England Wind, SFW = South Fork Wind, SW = Sunrise Wind, RW = Revolution Wind, and VW = Vineyard Wind.
[c] Due to earth's curvature and known WTG heights, those WTGs beyond 42.8 miles (68.9 kilometers) would not be visible from ground level plus 5.5 feet (1.7 meters).
[d] Noticeable elements: R = rotor, AL = aviation light, N = nacelle, H = hub, O = OSP, M = mid-tower light, Y = yellow tower base color.
[e] WTGs and OSP (onshore) visibility: 0 = Not visible. 1 = Visible only after extended study; otherwise not visible. 2 = Visible when viewing in general direction of the wind farm; otherwise likely to be missed by casual observer. 3 = Visible after brief glance in general direction of the wind farm; unlikely to be missed by casual observer. 4 = Plainly visible; could not be missed by casual observer, but does not strongly attract visual attention or dominate view. 5 = Strongly attracts viewers' attention to the wind farm; moderate to strong contrasts in form, line, color, or texture, luminance, or motion. 6 = Dominates view; strong contrasts in form, line, color, texture, luminance, or motion fill most of the horizontal FOV or vertical FOV (NAEP 2012).

This page intentionally left blank

H.3.2 Alternative C

Under Alternative C, the export cable route to Brayton Point would be rerouted onshore and follow one of two alternative corridors to avoid sensitive fish habitat in the Sakonnet River. Installation of these onshore export cables and infrastructure would result in localized, temporary visual impacts near construction sites due to land disturbance for vegetation clearing, site grading or trenching, and construction staging. These impacts would last through construction and continue until disturbed areas are restored.

H.3.3 Alternative D

Table H-18 and Table H-19 list Alternative D wind farm width-, height-, and distance-related occupation of views from the nearest shoreline area. These results indicate slight changes to the FOV results compared to the Proposed Action (Table H-4 and Table H-5).

Table H-18 Horizontal FOV occupied by Alternative D

Noticeable Element	Width miles (kilometers)	Distance miles (kilometers)	Horizontal FOV	Human FOV	Percent of FOV
D WTGs	12.3 (19.8)	23.6 (37.9)	26.2°	124°	21%

Table H-19 Vertical FOV occupied by Alternative D

Noticeable Element	Height feet (m) MLLW	Distance miles (kilometers)	Visible Height [a] feet (m)	Vertical FOV	Human FOV	Percent of FOV
D Rotor Blade Tip	1,066.3 (325.0)	23.6 (37.9)	779 (237)	0.3°	55°	0.5%

[1] Based on intervening EC and clear-day conditions.
M = meters; km = kilometers.

H.3.4 Alternatives E and F

Installation of different foundation types under Alternatives E-1, E-2, and E-3 would not change the most prominent visible aspects of WTGs and OSPs (e.g., blade height, hub height) and, therefore, would have no meaningful difference in impacts on seascape, open ocean, and landscape character units and viewer experience compared to the Proposed Action. The reduction in the number of cables installed along the Falmouth offshore export cable route under Alternative F may reduce the number of vessel trips required to install the cables, but this slight reduction in vessel activity would have no meaningful difference in impacts compared to the Proposed Action.

H.4 Seascape, Open Ocean, and Landscape Impact Assessment Summary

The SLIA considers the impacts on the physical elements and features that make up a seascape, open ocean, or landscape and the aesthetic, perceptual, and experiential aspects of the seascape, open ocean, or landscape that contribute to its distinctive character. These impacts affect the feel, character, or sense of place of an area of seascape, open ocean, or landscape. Table H-20 summarizes the effects of the character of the offshore and onshore components of the Project with the aspects that contribute to the distinctive character of the seascape, open ocean, and landscape areas from which the Project would be visible (BOEM 2021).

H.5 Visual Impact Assessment Summary

The VIA considers the characteristics of the view receptor, characteristics of the view toward the Project facilities, and the experiential impacts of the Projects. Table H-21 summarizes the viewer sensitivity, view receptor susceptibility, view value, and summary of the measures of effects from the visible character and magnitude of the offshore and onshore components of the Project (BOEM 2021).

Table H-20. Seascape character, open ocean character, landscape character and impact levels

Character Unit	Affected Environment										Proposed Action									Impact Levels				
	Unit Susceptibility			Unit Value			Project Visibility				Character Key Feature Change [a]			Character Key Element Change [b]			Character Key Quality Change [c]			Proposed Action				Alternatives C, D, E, and F

Appendix I: Finding of Adverse Effect for the SouthCoast Wind Construction and Operations Plan

Please note: This document reflects the status of NHPA Section 106 information and consultations as of October 29, 2024, and has mostly recently been revised based on Tribal Nation and consulting party feedback received during an NHPA review and comment period held from July 1–31, 2024.

The Bureau of Ocean Energy Management (BOEM) has made a Finding of Adverse Effect under Section 106 of the National Historic Preservation Act (NHPA) pursuant to 36 Code of Federal Regulations (CFR) 800.5 for the undertaking, defined as the construction, installation, operations and maintenance (O&M), and conceptual decommissioning of the SouthCoast Wind Project (Project), as described in the SouthCoast Wind Energy, LLC (SouthCoast Wind) Construction and Operations Plan (COP) (SouthCoast Wind 2024). The Project would have adverse effects on historic properties. As defined in 36 CFR 800.16(l)(1), the term *historic property* means "any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the National Register of Historic Places [NRHP; National Register] maintained by the Secretary of the Interior." The term *historic property* also includes National Historic Landmarks (NHLs) as well as sites of traditional religious and cultural importance to Tribal Nations that meet National Register criteria.

BOEM finds that the undertaking would adversely affect the following historic properties:

- One marine archaeological resource (Table I-5; Section I.3.1.1, *Assessment of Effects on Historic Properties in the Marine APE*).
- Two ancient submerged landform features (ASLFs) with potential or known archaeological or traditional cultural place (TCP) significance (Table I-7; Section I.3.1.1, *Assessment of Effects on Historic Properties in the Marine APE*).
- Two terrestrial archaeological resources (Table I-8; Section I.3.1.2, *Assessment of Effects on Historic Properties in the Terrestrial APE*).
- Two TCPs: Chappaquiddick Island and Nantucket Sound (Section I.3.1.1, *Assessment of Effects on Historic Properties in the Marine APE*; Section I.3.1.3, *Assessment of Effects on Historic Properties in the Visual APE*).
- Two aboveground historic properties: the Nantucket Historic District NHL and Oak Grove Cemetery (Section I.3.1.3, *Assessment of Effects on Historic Properties in the Visual APE*).

Per 36 CFR 800.5(a)(1), the Project would cause adverse effects on a historic property by altering, directly or indirectly, characteristics that qualify the historic property for inclusion in the National Register (refer to Section I.3, *Application of the Criteria of Adverse Effect*).

Construction of the Project would cause physical adverse effects on historic properties that are marine cultural resources (i.e., marine archaeological resources and ASLFs) in the marine portion of the area of potential effects (APE) and terrestrial archaeological resources in the terrestrial portion of the APE as

Project components and/or associated work zones are proposed for locations within the defined areas of these resources (COP, Appendices Q and R; SouthCoast Wind 2024). Additional terrestrial archaeological resources potentially subject to adverse effects from the Project may be identified during SouthCoast Wind's process of phased identification and evaluation of historic properties as defined in 36 CFR 800.4(b)(2) (COP, Appendix R.2; SouthCoast Wind 2024; Section I.5, *Phased Identification and Evaluation*).

The Project would also cause visual effects, and contribute to cumulative effects, on two historic properties that are TCPs: Chappaquiddick Island and Nantucket Sound. For Chappaquiddick Island TCP and Nantucket Sound TCP, BOEM determined that contributing historic aboveground elements would be visually affected by the visibility of Offshore Project components (COP, Appendix S; SouthCoast Wind 2024).

In addition to the two aforementioned TCPs, the Project would also cause visual effects from Project component visibility on two other aboveground historic properties: the Oak Grove Cemetery in Falmouth, Massachusetts, and Nantucket Historic District NHL (COP, Appendix S; SouthCoast Wind 2024). The Oak Grove Cemetery has landscape views that are a character-defining feature contributing to its NRHP eligibility; these landscape views are subject to adverse effects from Onshore Project components associated with the Lawrence Lynch substation. The Nantucket Historic District NHL has ocean views that are a character-defining feature contributing to the historic property's NRHP eligibility and subject to adverse effect from Offshore Project components. BOEM has determined that the Project would contribute to cumulative adverse effects from Offshore Project component visibility to this NHL. For compliance with NHPA Section 110(f) per 36 CFR 800.10, which applies specifically to NHLs, BOEM has determined that the Nantucket Historic District NHL would be adversely affected by the Project and has, to the maximum extent possible, undertaken planning and actions as may be necessary to minimize harm to the NHL.

BOEM elected to use the National Environmental Policy Act (NEPA) substitution process for Section 106 purposes, as described in 36 CFR 800.8(c), during its review. The regulations at 36 CFR 800.8(c) provide for use of the NEPA substitution process to fulfill a federal agency's NHPA Section 106 review obligations in lieu of the procedures set forth in 36 CFR 800.3 through 800.6. The NEPA substitution process is described at https://www.achp.gov/integrating_nepa_106. Both NEPA and Section 106 allow participation of consulting parties. Consistent with use of the NEPA substitution process to fulfill Section 106 requirements, BOEM has stipulated mitigation measures to resolve adverse effects in a Memorandum of Agreement (MOA) pursuant to 36 CFR 800.8(c)(4)(i)(B). Simultaneous to the publication of this Final EIS, BOEM is coordinating with signatories to the MOA to have the MOA fully signed and executed no later than December 19, 2024. The version of the MOA, attached to this document as Attachment A, is a draft of the MOA as of September 30, 2024. The executed MOA will be posted on BOEM's website following issuance of the Record of Decision (ROD): https://www.boem.gov/renewable-energy/state-activities/southcoast-wind-formerly-mayflower-wind.

I.1 Project Overview

In February 2021, BOEM received a COP from SouthCoast Wind proposing an offshore wind energy facility in Renewable Energy Lease Area OCS-A 0521 (Lease Area), offshore Massachusetts. In addition, SouthCoast Wind submitted updates to the COP in August 2021, October 2021, March 2022, December 2022, and September 2023. In its COP, SouthCoast Wind proposes construction and installation, O&M, and conceptual decommissioning of an up to 2,400-megawatt (MW) wind energy project consisting of offshore wind turbine generators (WTGs) and their foundations, offshore substation platforms (OSPs) and their foundations, scour protection for foundations, interarray cables linking the individual turbines to the OSPs, offshore export cables and an onshore export cable system, onshore substations, and connections to the existing electrical grid in Massachusetts (Figure I-1). At their nearest point, WTG and OSP components of the Project would be approximately 26 nautical miles (30 statutory miles, 48 kilometers) south of Martha's Vineyard and 20 nautical miles (23 statutory miles, 37 kilometers) south of Nantucket, Massachusetts. Offshore Project components would be on the OCS, with the exception of portions of the offshore export cables in Massachusetts and Rhode Island state waters. SouthCoast Wind is using a Project Design Envelope (PDE) in its COP, which represents a reasonable range of design parameters that may be used for the Project. In reviewing the PDE, BOEM is analyzing the maximum-case scenario that could occur from any combination of the contemplated parameters. This includes any Project alternatives that may require phased identification of historic properties (COP, Appendix R.2; SouthCoast Wind 2024; Section I.5, *Phased Identification and Evaluation*). BOEM's analysis and review of the PDE may result in the approval of a project that is constructed within that range or a subset of design parameters within the proposed range.

If approved by BOEM and other agencies with authority to approve Project components outside of BOEM's jurisdiction, SouthCoast Wind would construct and operate WTGs, export cables to shore, and associated facilities, including those outside BOEM's jurisdiction, for a specified term. BOEM is now conducting its environmental and technical reviews of the COP and has published a Final Environmental Impact Statement (EIS) under NEPA for its decision regarding approval of the plan. A detailed description of the proposed Project can be found in Chapter 2, *Alternatives*, of the Final EIS. This Final EIS considers reasonably foreseeable impacts of the Project, including impacts on cultural resources, which include historic properties.

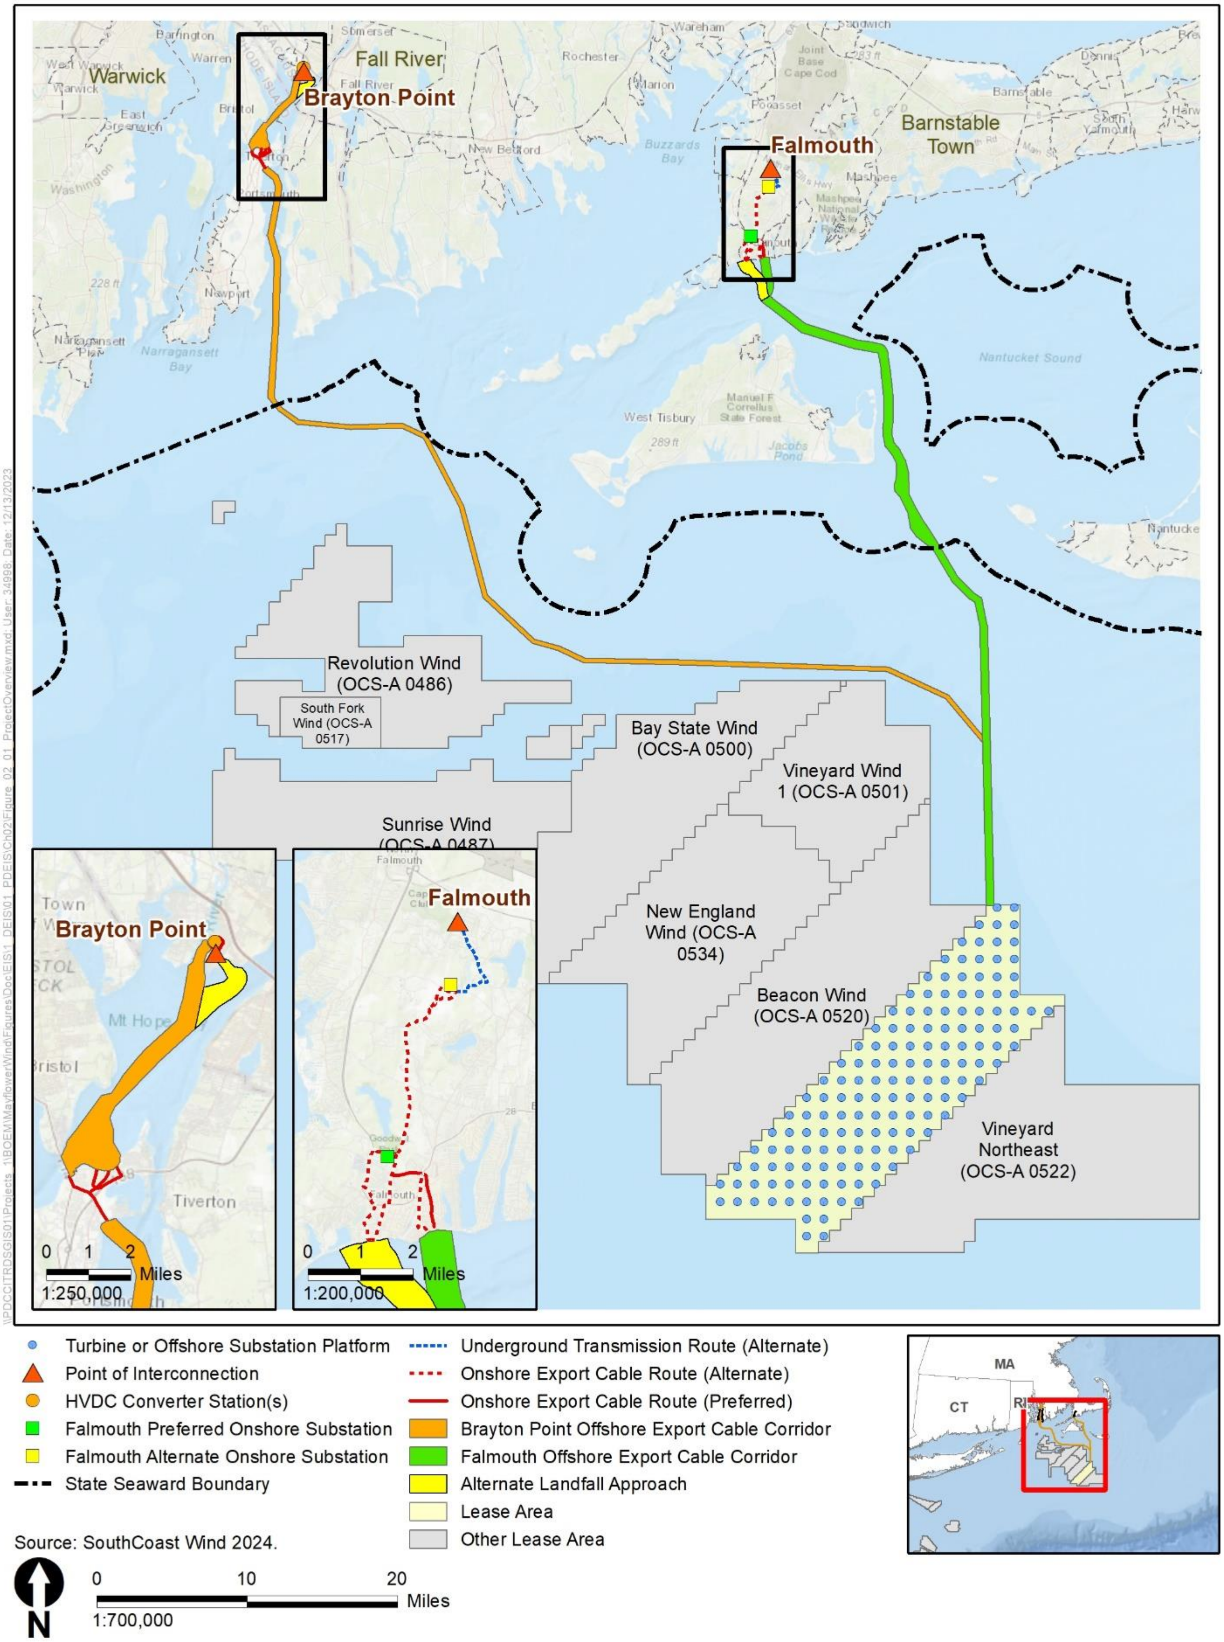

Figure I-1. SouthCoast Wind COP proposed Project elements

I.1.1 Background

The Project is in a commercial lease area that received previous Section 106 review by BOEM regarding the issuance of the commercial lease and approval of site assessment activities.

On February 6, 2012, BOEM published in the *Federal Register* (FR) a *Notice of Intent to Prepare an Environmental Assessment for Commercial Wind Lease Issuance and Site Characterization Activities on the Atlantic OCS Offshore Massachusetts* (77 FR 5830). On November 2, 2012, BOEM announced the availability of an environmental assessment (EA) for public review and comment (77 FR 66185). BOEM considered comments received from this notice and on June 18, 2014, made available a revised EA for the Wind Energy Area (WEA) offshore Massachusetts (79 FR 34781). As a result of the analysis in the revised EA, BOEM issued a Finding of No Significant Impact, which concluded that reasonably foreseeable environmental effects associated with commercial wind lease issuance and related site assessment activities would not significantly affect the environment. The Section 106 process was completed pursuant to a programmatic agreement (PA), executed on June 8, 2012 (*Programmatic Agreement among the U.S. Department of the Interior, Bureau of Ocean Energy Management; the State Historic Preservation Officers of Massachusetts and Rhode Island; the Mashpee Wampanoag Tribe; the Narragansett Indian Tribe; the Wampanoag Tribe of Gay Head (Aquinnah); and the Advisory Council on Historic Preservation Regarding the "Smart from the Start" Atlantic Wind Energy Initiative: Leasing and Site Assessment Activities Offshore Massachusetts and Rhode Island*) and concluded with a BOEM determination of no historic properties affected for lease issuance, corresponding to the Finding of No Significant Impact for the EA. On December 2018, BOEM held a competitive lease sale for WEAs offshore Massachusetts. SouthCoast Wind was identified as the winner of Lease Area OCS-A 0521.

Subsequent to award of the lease, SouthCoast Wind submitted a site assessment plan describing the proposed installation, O&M, and decommissioning of a meteorological buoy within the Lease Area. Pursuant to Stipulation 1 of the PA, BOEM issued a Finding of No Historic Properties Affected on January 28, 2020 and notified the signatories of the PA to the finding.

SouthCoast Wind's COP proposed to develop the entire Lease Area as an offshore wind renewable energy project. The Project would consist of up to 149 positions in the Lease Area to be occupied by WTGs and OSPs. The 149 positions would conform to a 1.0-by-1.0-nautical mile (1.9-by-1.9-kilometer) grid layout with an east–west and north–south orientation across the entire Massachusetts Rhode Island Wind Energy Area (MA/RI WEA), as agreed upon by SouthCoast Wind and the other MA/RI WEA leaseholders. WTGs, which would be up to 1,066 feet tall above mean sea level, and OSPs would be connected via interarray cables in the Lease Area. The Project would be developed in two parts or projects: Project 1 refers to the development in the northern portion of the Lease Area and associated interconnection, and Project 2 refers to the development in the southern portion of the Lease Area and associated interconnection.

The Project would include one preferred export cable corridor (ECC) making landfall and interconnecting to the ISO New England Inc. (ISO-NE) grid at Brayton Point in Somerset, Massachusetts. This preferred ECC to Brayton Point will be used for both Project 1 and Project 2 within the Lease Area. The Project will also include one variant ECC which, if utilized, would make landfall and interconnect to the ISO-NE grid in the town of Falmouth, Massachusetts. In the event that technical, logistical, grid interconnection, or other unforeseen challenges arise during the design and engineering phase that prevent Project 2 from making interconnection at Brayton Point, Project 2 will utilize the Falmouth variant ECC and make landfall and interconnect in Falmouth, Massachusetts.

Within the Brayton Point ECC, up to six submarine offshore export cables, including up to four power cables and up to two dedicated communications cables, would be installed from one or more OSPs in the Lease Area on the OCS, and run through the Sakonnet River, make intermediate landfall on Aquidneck Island in Portsmouth, Rhode Island, which includes an underground onshore export cable route, and then into Mount Hope Bay, to make landfall at Brayton Point in Somerset, Massachusetts. The two landfall sites considered in the PDE include developed coastal locations on either side of Brayton Point: the Western landfall from the Lee River and the Eastern landfall from the Taunton River.

Within the variant Falmouth ECC, up to five submarine offshore export cables, including up to four power cables and up to one dedicated communications cable, would be installed from one or more OSPs in the Lease Area on the OCS, and run through Muskeget Channel into Nantucket Sound in Massachusetts state waters, to make landfall in Falmouth, Massachusetts. The three landfall sites considered in the PDE include coastal locations at the end of Worcester Avenue, Central Park, and Shore Street.

SouthCoast Wind would use horizontal directional drilling (HDD) for the sea-to-shore transition of export cables between the ocean and the land. For the offshore export cable landfall sites at Brayton Point in Somerset, Massachusetts, up to four new underground onshore export power cables would transmit the Project's high-voltage direct-current (HVDC) electric generation to up to two new, SouthCoast Wind-developed onshore HVDC converter stations. The onshore converter stations are specialized electrical substations designed to convert the HVDC power from the export cables to high-voltage alternating-current power to enable interconnection to the existing transmission infrastructure. The new underground 345-kV transmission line would be constructed entirely within the previously disturbed industrial Brayton Point property. The underground transmission line would connect the converter stations to the existing National Grid Substation at Brayton Point in Somerset, Massachusetts, the Brayton Point POI. Collectively, these onshore components at Brayton Point in Somerset, Massachusetts are referred to as the Brayton Point Onshore Project Area.

For the variant Falmouth interconnection, up to 12 new underground onshore export power cables would transmit the proposed Project's electric generation from the landfall site to a new SouthCoast Wind-developed onshore substation. The onshore export cables would travel underground from the landfall location to the newly constructed onshore substation, located in Falmouth, Massachusetts. There are two onshore substation locations under consideration in Falmouth, Massachusetts consisting of the potential Lawrence Lynch (preferred) substation site and the potential Cape Cod Aggregates (alternative) substation site. The onshore substation would transform the export cable voltage to 345 kilovolts (kV) to enable connection to the transmission line. Eversource Energy (Eversource) would be responsible for designing, permitting, constructing, and operating the overhead transmission line in

Eversource Right-of-Way #341 that would connect the proposed onshore substation to the existing POI at Falmouth Tap in Falmouth, Massachusetts; the overheard transmission line is not considered part of the PDE. Alternatively, the Project is also considering an underground transmission route, which would connect the onshore substation to the Falmouth POI. Collectively, these onshore components in Falmouth, Massachusetts are referred to as the Falmouth Onshore Project Area.

The proposed Project has a designed life span of approximately 35 years; some installations and components may remain fit for continued service after this time. O&M activities would include inspections, preventative maintenance, and, as needed, corrective maintenance for onshore substations, onshore export cables, and grid connections. SouthCoast Wind would conduct annual maintenance of WTGs, including safety surveys of lifesaving equipment. Substructures would undergo internal and external inspections every 2 years. SouthCoast Wind would need to use vessels, vehicles, and aircraft during O&M activities.

Although the proposed Project is anticipated to have an operational life of 35 years, it is possible that some installations and components may remain fit for continued service after this time. SouthCoast Wind would have to apply for and be granted a renewal of the operations term of its lease under BOEM’s regulations at 30 CFR 585.425, et seq., if it wanted to operate the proposed Project for more than the 33-year operations term stated in its lease. The process of decommissioning would remove all facilities, cables, pipelines, and obstructions and clear the seafloor of all obstructions created by the proposed Project. All foundations would need to be removed 15 feet (4.6 meters) below the mudline (30 CFR 285.910(a)). Absent permission from BOEM, SouthCoast Wind would have to achieve complete decommissioning within 2 years of termination of the lease and either reuse, recycle, or responsibly dispose of all materials removed. A Section 106 review would be conducted at the decommissioning stage.

I.1.2 Undertaking

BOEM has determined that the Project constitutes an undertaking subject to Section 106 of the NHPA as amended (54 USC 306108) and its implementing regulations (36 CFR 800), and the Project activities proposed under the COP have the potential to affect historic properties. Confidential appendices to the COP referenced in this document were sent electronically or by mail depending on expressed preference to consulting parties on February 2, 2023, January 17, 2024, and September 30, 2024. The COP, as well as its public and confidential appendices, is hereby incorporated by reference.

The undertaking for this Section 106 review is the Proposed Action. As described in Chapter 2, Section 2.1.2, *Alternative B – Proposed Action*, of the Final EIS, the Proposed Action would include the construction, installation, O&M, and conceptual decommissioning of a wind energy facility on the OCS offshore Massachusetts, occurring within the range of design parameters outlined in the COP (SouthCoast Wind 2024), subject to applicable mitigation measures. BOEM’s election to use NEPA substitution for the Section 106 review of the Project includes the identification and evaluation of historic properties for the undertaking and assessment of effects for all the action alternatives identified during the NEPA review and as presented in the Final EIS. For BOEM's assessment of the action alternatives, see Section I.4.1, *Alternatives Considered*.

I.1.3 Area of Potential Effects

Per 36 CFR 800.16(d), the APE is defined as "the geographic area or areas within which an undertaking may directly or indirectly cause alterations in the character or use of historic properties, if any such properties exist." BOEM (2020) defines the APE for the undertaking to include the following areas:

- The depth and breadth of the seabed potentially impacted by any bottom-disturbing activities, constituting the marine portion of the APE.
- The depth and breadth of terrestrial areas potentially impacted by any ground-disturbing activities, constituting the terrestrial portion of the APE.
- The viewshed from which renewable energy structures, whether offshore or onshore, would be visible, constituting the visual portion of the APE.
- Any temporary or permanent construction or staging areas, both onshore and offshore, which may fall into any of the above portions of the APE.

These are described below in greater detail with respect to the proposed activities, consistent with BOEM's *Guidelines for Providing Archaeological and Historic Property Information Pursuant to 30 CFR Part 585* (BOEM 2020). Refer to Attachment B, Figure I.B-1 for an overview map of the Project APE.

I.1.3.1 Marine Portion of the APE

The marine portion of the APE (hereafter referred to as the *marine APE*) for the Project is the depth and breadth of the seabed potentially impacted by any bottom-disturbing activities and temporary or permanent offshore construction or staging areas. It includes a conservative PDE that can accommodate a number of potential designs, whether piled or suction bucket foundations are used and installed by jack-up vessels as well as necessary support vessels and barges. The marine APE (Figure I.B-2) encompasses activities in the Lease Area (Figure I.B-3), Falmouth offshore ECC (Figure I.B-4), and Brayton Point offshore ECC (Figure I.B-5). The defined vertical extent of the marine APE, as discussed below, varies based on the type of Offshore Project component and accounts for the maximum vertical burial depth and seabed disturbance identified for each of those Project components and their installation.

The Lease Area encompasses 127,388 acres (51,552 hectares) with water depths ranging from 121.7 feet (37.1 meters) to 208.3 feet (63.5 meters) in relation to mean lower low water (MLLW) (COP Volume 1, Section 1.2; SouthCoast Wind 2024). In the Lease Area, SouthCoast Wind proposes up to 149 positions to be occupied by WTGs and OSPs. WTGs and OSPs would be connected via interarray cables in the Lease Area.

The marine APE also includes offshore portions of the two proposed ECCs: Brayton Point and Falmouth ECCs (COP Volume 1, Section 3.3.5 and Table 3-14; SouthCoast Wind 2024). Within the maximum 124-

mile (200-kilometer) long preferred Brayton Point ECC, up to six submarine offshore export cables would be installed from one or more OSPs in the Lease Area on the OCS, and run through the Sakonnet River, make intermediate landfall on Aquidneck Island in Portsmouth, Rhode Island, which includes an underground onshore export cable route, and then into Mount Hope Bay, to make landfall at Brayton Point in Somerset, Massachusetts. Within the maximum 87.0-mile (140.0-kilometer) long variant Falmouth ECC, if it is used, up to five submarine offshore export cables would be installed from one or more OSPs in the Lease Area on the OCS and would run through Muskeget Channel into Nantucket Sound in Massachusetts state waters, to make landfall in Falmouth, Massachusetts. SouthCoast Wind intends to maintain an ECC width of between 2,625 feet to 3,280 feet (800 meters to 1,000 meters) for the Falmouth ECC and between 1,640 feet to 2,300 feet (500 meters to 700 meters) for the Brayton Point ECC to allow for maneuverability during installation and maintenance. The offshore ECCs may be locally narrower or wider to accommodate sensitive locations and to provide sufficient area at landfall locations, at crossing locations, or for anchoring (COP Volume 1, Section 3.3.5.2; SouthCoast Wind 2024).

SouthCoast Wind would use horizontal directional drilling (HDD) for the sea-to-shore transition of export cables between the ocean and the land. Two potential sea-to-shore transition (landfall) locations at Brayton Point in Somerset, Massachusetts, four potential locations on Aquidneck Island in Portsmouth, Rhode Island, and three potential sea-to-shore transition (landfall) locations in Falmouth, Massachusetts are under consideration. The submerged areas of these activities are included in the marine APE; the landfall locations and related HDD activities located onshore are included in the terrestrial APE (discussed in section that follows).

The approximate maximum horizontal area and vertical depth of seabed disturbance associated with the construction or installation each of these aforementioned Offshore Project components and composing the marine APE are provided in Table I-1.

Table I-1. Approximate maximum horizontal and vertical extents of seabed disturbance for construction of Offshore Project components composing the marine APE

<table>
<tr><th rowspan="2">Project Component</th><th colspan="2">Seabed Disturbance</th></tr>
<tr><th>Maximum Horizontal Area</th><th>Maximum Vertical Depth</th></tr>
<tr><td>Per WTG foundation</td><td>22.2 ac (9.0 ha);

<tr><td>Brayton Point HDD</td><td>98 ft (30 m)</td></tr>
<tr><td>Aquidneck Island HDD</td><td>98 ft (30 m)</td></tr>
</table>

Project Component	Seabed Disturbance	
	Maximum Horizontal Area	Maximum Vertical Depth
Falmouth offshore ECC (Variant)	2,624-3,280 ft (800-1,000 m) centered on the cables along their entire length	16.4 ft (5.0 m)
Falmouth HDD		98 ft (30 m)

Notes: Cable corridors may be locally wider in specific areas to allow for micro-routing and hazard avoidance. Cables may be micro-routed within the defined and surveyed horizontal marine APE extent.
Source: COP Volume 2, Table 7-1 and Appendix II-Q1, Tables II-1 and II-2; SouthCoast Wind 2024.
ac = acres; ft = feet; ha = hectares; m = meters.

I.1.3.2 Terrestrial Portion of the APE

The terrestrial portion of the APE (hereafter referred to as the *terrestrial APE*) includes the depth and breadth of terrestrial areas potentially impacted by any ground-disturbing activities and temporary or permanent onshore construction or staging areas. The APE is presented as part of a conservative PDE and includes the export cable landfall sites, onshore export cable routes and associated installation areas, onshore HDD areas, onshore substation, and converter stations. Figure I.B-6 depicts the terrestrial APE for onshore cable and landfall site options in Falmouth, Massachusetts. Figure I.B-7 depicts the terrestrial APE for onshore cable and landfall site options in Aquidneck Island in Portsmouth, Rhode Island and Somerset, Massachusetts. Figure I.B-8 depicts the terrestrial APE for onshore cable and landfall site options in Brayton Point in Somerset, Massachusetts. The defined vertical extents of the terrestrial APE, as discussed below, vary based on the type of Onshore Project component and account for the maximum burial depth and vertical ground disturbance identified for each of those Project components and their installation.

The terrestrial APE includes the sea-to-shore transition landfall sites. Two potential sea-to-shore transition locations at Brayton Point in Somerset, Massachusetts, four potential locations on Aquidneck Island in Portsmouth, Rhode Island, and two potential locations in Falmouth, Massachusetts are under consideration (COP Volume 1, Section 3.3.6; SouthCoast Wind 2024). The landfall locations at Brayton Point in Somerset, Massachusetts include the western landfall location from the Lee River and the eastern landfall location from the Taunton River. Additionally, the Brayton Point offshore export cables would make intermediate landfall on Aquidneck Island in Portsmouth, Rhode Island. This landfall would require HDDs at two locations: one entering and one exiting Aquidneck Island. One landfall location is under consideration for entering Aquidneck Island; three route options, one of which has two sub-options, are under consideration for exiting Aquidneck Island. The landfall locations in Falmouth, Massachusetts include Worcester Avenue, Central Park, and Shore Street. At all potential landfall locations, including those on Aquidneck Island, SouthCoast Wind would use HDD to transition between ocean and land (COP Volume 1, Section 3.3.6; SouthCoast Wind 2024).

From the landfall site options, the underground onshore export cables would be routed to the new onshore substation or converter stations, depending on the landfall location (COP Volume 1, Sections 3.3.6 and 3.3.7; SouthCoast Wind 2024). The onshore export cables would be installed in existing roadways, where feasible. As the preferred ECC for Projects 1 and 2, one of two Brayton Point onshore export cable routes from the landfall site options would be used based on landfall site selection. If the

Brayton Point ECC cannot be used for Project 2, one of three Falmouth onshore export cable routes from the landfall site options would be used based on landfall site selection. For the preferred Brayton Point onshore export cable route options, the maximum length would be 3,940 feet (1,200 meters; COP Volume 1, Table 3-18; SouthCoast Wind 2024). Additionally, an intermediate landfall would occur on Aquidneck Island in Portsmouth, Rhode Island, including a 3-mile (4.8-kilometer) underground onshore export cable route, as part of the Brayton Point export cable route. For the variant Falmouth onshore export cable route options, the minimum length would be 1.9 miles (3.0 kilometers) and maximum length would be 6.4 miles (10.3 kilometers) (COP Volume 1, Table 3-18; SouthCoast Wind 2024). The maximum width of the trench excavation for cable installation is anticipated to be approximately 11.0 feet (3.3 meters) per trench (COP Volume 1, Section 3.3.7.1; SouthCoast Wind 2024). In areas where trench boxes cannot be used, the maximum width of disturbance would be 35.0 feet (10.7 meters) per trench

The onshore cables would connect to the proposed onshore substation and converter stations. SouthCoast Wind would commission the development of up to two new HVDC converter stations to convert the Project's HVDC power for interconnection with the Brayton Point POI. The converter stations would be constructed at the site of the former Brayton Point Power Station. If the variant Falmouth ECC is used for Project 2, SouthCoast Wind would commission the development of one new onshore substation to transform the underground export cable transmission circuit for interconnection with the Falmouth POI (COP Volume 1, Section 3.3.8; SouthCoast Wind 2024). There are two onshore substation locations under consideration for the variant Falmouth ECC, including the Lawrence Lynch site at 396 Gifford Street (Option A) and Cape Cod Aggregates site at 469 Thomas Landers Road (Option B).

Since a final determination for the location(s) of the O&M facility has not yet been made, the terrestrial and visual APE for the O&M facility will be defined using a process of phased identification and evaluation, in consultation with BOEM and the State Historic Preservation Officer (SHPO), as defined in 36 CFR 800.4(b)(2).

The approximate maximum horizontal area and vertical depth of ground disturbance associated with constructing or installing each of the aforementioned Onshore Project components and composing the terrestrial APE are provided in Table I-2.

Table I-2. Approximate maximum horizontal and vertical extents of ground disturbance for construction of Onshore Project components composing the terrestrial APE

Project Component		Ground Disturbance (per Project Component)	
		Maximum Horizontal Area	Maximum Vertical Depth
Brayton Point (Preferred)	Export cable landfall	1.2 ac (0.49 ha)	90 ft (27 m)
	Onshore export cable installation area	2.2 ac (0.89 ha)	25 ft (7.6 m)
	Converter stations	10 ac (4.0 ha)	60 ft (18.3 m)
	Underground transmission route	2.2 ac (0.89 ha)	25 ft (7.6 m)

Project Component		Ground Disturbance (per Project Component)	
		Maximum Horizontal Area	Maximum Vertical Depth
Aquidneck (Preferred)	Export cable landfall	1.6 ac (0.65 ha)	90 ft (27 m)
	Onshore export cable route	8.5 ac (3.4 ha)	25 ft (7.6 m)
	Export cable route departure (HDD)	1.8 ac (0.73 ha)	90 ft (27 m)
Falmouth (Variant)	Export cable landfall	2.5 ac (1.0 ha)	90 ft (27 m)
	Onshore export cable installation area	36.2 ac (14.6 ha)	25 ft (7.6 m)
	Onshore substation	31 ac (12.5 ha)	60 ft (18.3 m)
	Underground transmission route	9.0 ac (3.6 ha)	25 ft (7.6 m)

Source: COP Volume 2, Table 7-3; SouthCoast Wind 2024.
ac = acres; ft = feet; ha = hectares; HDD = horizontal directional drilling; m = meters.

I.1.3.3 Visual Portion of the APE

The visual portion of the APE (hereafter referred to as the visual APE) includes the viewshed from which renewable energy structures—whether offshore or onshore—would be visible.

Development of the visual APE for Offshore Project components begins with a boundary of 43 miles radial distance from the Lease Area, which is the approximate maximum theoretical distance—a distance that does not factor in certain environmental factors such as weather or environmental conditions—at which the WTGs could be visible (COP, Appendix S; SouthCoast Wind 2024). Geographic information system analysis and subsequent field investigation delineated the visual APE for Offshore Project components methodically through a series of steps, beginning with the maximum theoretical distance WTGs could be visible. This was determined by first considering the visibility of a WTG from the water level to the tip of an upright rotor blade at a height of 1,066.3 feet (325 meters). The analysis then accounted for how distance and Earth curvature impede visibility as the distance increases between the viewer and WTGs (i.e., by a 43-mile distance, even blade tips would be below the sea level horizon line). The mapping effort then removed all areas with obstructed views toward WTGs, such as those views impeded by intervening topography, vegetation, and structures. Areas with unobstructed views of Offshore Project components then constituted the APE. Based on this analysis, the visual APE for Offshore Project components is defined as portions of the Preliminary APE, which includes all areas with views of the Offshore Project components located within 1 mile (1.6 kilometers) of the southern shorelines of Martha’s Vineyard and Nantucket (COP, Appendix S; SouthCoast Wind 2024). Figures I.B-9 through I.B-11 show the visual APE for Offshore Project components. Development of the visual APE for Onshore Project components followed a similar process. The Preliminary visual APE for the Brayton Point Onshore Project area (preferred) was developed based on the maximum height of the onshore structures, including temporary and permanent construction and staging areas, and was refined based on areas of potential visibility through viewshed modeling. Views were verified through field visits in sensitive viewpoints identified in the resultant viewshed, which was determined to be a 0.5-mile (0.8-kilometer) radius around the converter stations siting area (Figure I.B-14; COP, Appendix S.1; SouthCoast Wind 2024). Similarly, a preliminary viewshed was established for the onshore substation locations under consideration in the Falmouth Onshore Project area (variant option), including Lawrence Lynch

(Figure I.B-12) and Cape Cod Aggregates substation (Figure I.B-13), based on the maximum height of the onshore structures, and was refined based on areas of potential visibility. The resultant visual APE reflects the maximum visibility of the substation structures, which considers screening associated with intervening topography, vegetation, and structures. The Preliminary APE for each onshore substation in the Falmouth Onshore Project area is based on actual field verified visibility and is limited to an area extending 0.1 mile (0.16 kilometer) from the substation boundary (COP, Appendix S; SouthCoast Wind 2024). Onshore export cables and transmission routes are anticipated to have only temporary visual effects on aboveground historic properties and TCPs during the construction phase (COP Volume 2, Section 7.3; SouthCoast Wind 2024); therefore, these areas are not included in the visual APE for Onshore Project components. Figures I.B-12 through I.B-14 show the visual APE for Onshore Project components.

BOEM released a technical memorandum delineating the APE on February 2, 2023, and updated June 5, 2024, concurring with the scope and boundaries of the Project APE as defined in the SouthCoast Wind technical reports.

I.2 Steps Taken to Identify Historic Properties

I.2.1 Technical Studies and Reports

To support the identification of historic properties in the APE, SouthCoast Wind has provided technical reports detailing the results of cultural resource investigations in the marine, terrestrial, and visual portions of the APE. Table I-3 provides a summary of these efforts to identify historic properties and the results and key findings of each investigation. Collectively, BOEM finds that these reports represent a good-faith effort to identify historic properties in portions of the Project APE that are not subject to the phased identification process. The documents summarized in Table I-3 have been shared with consulting parties and are hereby incorporated by reference.

BOEM has reviewed the reports summarized in Table I-3, found them sufficient, and reached the following conclusions:

- BOEM has reviewed the Marine Archaeological Resources Assessment (MARA) Report and has determined that the data are sufficient for identifying historic properties in the marine APE.
- BOEM has reviewed the Terrestrial Archaeological Resources Assessment (TARA) Reports and Phased Identification Plan (PIP) and determined that the completed and planned investigations summarized in the documents will be sufficient for identifying historic properties in the terrestrial APE. Efforts conducted for the TARA thus far are sufficient for determining effects on some identified historic properties, but given logistical limitations, not all of the terrestrial APE has been fully investigated. SouthCoast Wind will be using phased identification of historic properties, as defined in 36 CFR 800.4(b)(2), for completion of archaeological investigations in the terrestrial APE, a process specifically provided for in the MOA that will be issued pursuant to 36 CFR 800.8(c)(4)(i)(B). Refer to Section I.5, *Phased Identification and Evaluation,* for additional details on the phased process, and Attachment A for a draft of the MOA as of September 30, 2024.

- BOEM has reviewed the Analysis of Visual Effects to Historic Properties (AVEHP) Reports and determined the studies and reports are sufficient for identifying and assessing effects on historic properties in the visual APE. BOEM finds that the APE for potential visual effects analyzed is appropriate for the scale and scope of the undertaking.

In addition to these conclusions, BOEM has found that the assessment of effects on historic properties in the marine, terrestrial, and visual APEs contained in these reports is sufficient to apply the criteria of adverse effects and continue consultations with consulting parties for resolving adverse effects on historic properties.

Consequent to the reports prepared for the COP submittal, ICF prepared for BOEM a technical report to support BOEM's cumulative effects analysis, the *Cumulative Historic Resources Visual Effects Analysis for SouthCoast Wind Energy Project* (BOEM 2023). The Cumulative Historic Resources Visual Effects Assessment (CHRVEA) presents the analysis of cumulative visual effects where BOEM, in review of the AVEHP (COP, Appendix S; SouthCoast Wind 2024), has determined that Offshore Project components would cause adverse visual effects on historic properties (BOEM 2023). The effects of other reasonably foreseeable wind energy development activities are additive to those adverse effects from the Project, resulting in cumulative effects. Three aboveground historic properties in the viewshed of WTGs for the Project and other reasonably foreseeable offshore wind energy development activities would be adversely affected by cumulative visual effects: the Chappaquiddick Island TCP, Nantucket Historic District NHL, and Nantucket Sound TCP.

Table I-3. Summary of cultural resources investigations performed by SouthCoast Wind in the Project APE

Portion of APE	Report	Description	Key Findings/ Recommendations
Marine	*Marine Archaeological Resources Assessment for the SouthCoast Wind Project Located in Massachusetts and Rhode Island State Waters and OCS Block OCS-A 0521 Offshore Massachusetts* (COP, Appendix Q; SouthCoast Wind 2024)	Marine Archaeological Resources Assessment. Prepared by RCG&A. Assessment of HRG survey data collected during multiple non-intrusive survey campaigns conducted by marine survey contractors and geotechnical investigations in the marine APE representing the extent of anticipated seabed impacts associated with the Project.	RCG&A identified 50 potential marine archaeological resources: five in the Lease Area, 16 in the Falmouth ECC, 25 in the Brayton Point ECC, and four outside the marine APE but included in the report. Upon review of the HRG survey data, 32 of the 46 targets in the marine Preliminary APE (PAPE) have been recommended for avoidance due to their potential cultural significance. The remaining 14 targets were determined to not be culturally significant; therefore, avoidance of these targets was not recommended. RCG&A also identified nine ASLFs in the marine PAPE and seven outside the marine PAPE. All ASLFs in the marine APE have been recommended for avoidance with an avoidance buffer derived from a review of seismic profiles and informed by the ground model to ensure that it covers the extent of the potentially preserved features. The Nantucket Sound TCP was also identified in the marine APE.
Terrestrial	*Archaeological Reconnaissance Survey of SouthCoast Wind Project, Falmouth, Barnstable County, Massachusetts* (COP, Appendix R; SouthCoast Wind 2024)	Terrestrial Archaeological Resources Assessment: Falmouth Phase IA Report. Prepared by AECOM. Background research of known cultural resources, development of archaeological sensitivity model, and reconnaissance-level field assessment of existing field conditions in the Falmouth, Barnstable County, MA portion of the terrestrial APE.	AECOM conducted a reconnaissance study for Onshore Project components in Falmouth, Barnstable County, MA. The survey area included roughly 10.0 mi (16.1 km) of linear routes along with an additional 64 ac (25.9 ha) in larger areas at proposed sea-to-shore transition and facility sites. The reconnaissance survey includes a contextualizing review of existing documentation. Based on that review, an archaeological sensitivity model was developed, identifying much of the survey area to be archaeologically sensitive due to the desirable environmental features that have made the area a place of human habitation for millennia. Lastly, a field assessment was conducted to document existing conditions and provide further nuance to the overall sensitivity. The entire survey area was surveyed, which included 13 soil profiles sampled using a 1-3/8-in diameter split-spoon hand

Portion of APE	Report	Description	Key Findings/ Recommendations
			auger. Additionally, geotechnical borings were assessed for potential buried landscapes at two of the landfall locations.
Terrestrial	Intensive (Locational) Archaeological Survey and Archaeological Construction Monitoring Plan (COP, Appendix R; SouthCoast Wind 2024)	Terrestrial Archaeological Resources Assessment: Falmouth Phase 1B Work Plan. Prepared by AECOM. Work and archaeological construction monitoring plan for AECOM to conduct archaeological field investigation in Falmouth, Barnstable County, MA on behalf of SouthCoast Wind.	No substantive findings or recommendations beyond those presented in *Archaeological Reconnaissance Survey of SouthCoast Wind Project, Falmouth, Barnstable County, Massachusetts* (COP, Appendix R; SouthCoast Wind 2022). Contains work and archaeological construction monitoring plan to conduct archaeological field investigation in Falmouth, Barnstable County, MA.
Terrestrial	*Terrestrial Archaeological Resources Assessment, SouthCoast Wind Offshore Wind Project: Brayton Point HVDC Converter Station Onshore Facilities and Underground Cable Route* (COP, Appendix R; SouthCoast Wind 2024)	Terrestrial Archaeological Resources Assessment: Brayton Point Phase 1A Report. Prepared by PAL. Background research of known cultural resources, previous and current land use, and assessment of archaeological sensitivity in the Somerset, Bristol County, MA portion of the terrestrial APE.	PAL conducted a field assessment for the proposed Brayton Point HVDC converter station onshore component of the Project in Somerset, Bristol County, MA. Historical maps and aerial imagery document substantial development in the Project area since the mid-20th century that includes canal excavation and infilling, power generation facilities improvements and demolition, and environmental management (landfill burial) of waste coal ash. Although pre- and post-Contact archaeological resources have been recorded on Brayton Point and the adjacent area, significant disturbance from previous construction has occurred. Installation of the Brayton Point HVDC converter station, underground cable system, and HDD sites are unlikely to affect any historic properties potentially eligible for listing in the State or NRHP, and no further archaeological investigation was recommended.
Terrestrial	*Terrestrial Archaeological Resources Assessment, SouthCoast Wind Project, Aquidneck Island (Portsmouth) Landfall* (COP, Appendix R; SouthCoast Wind 2024)	Terrestrial Archaeological Resources Assessment: Aquidneck Phase 1A/1B Report. Prepared by PAL. Background research of known cultural resources, previous and current land use, assessment of archaeological sensitivity, and Phase IB subsurface archaeological survey in the Portsmouth, Newport County, RI portion of the terrestrial APE.	Two terrestrial archaeological resources were newly identified in Phase IB survey. Both resources were recommended as potentially eligible for the NRHP under Criteria A and D and for avoidance and/or construction monitoring by the Project. Phase IB survey of Route Segment F and Mount Hope Bridge HDD Option 4 was recommended if Segment F is selected as the preferred duct bank alternate. Archaeological monitoring of HDD Options 1 and 3 was recommended to document any pre- or post-Contact

Portion of APE	Report	Description	Key Findings/ Recommendations
			archaeological features or deposits that may be encountered during boring for the HDDs. No archaeological testing was conducted along Boyds Lane north of Anthony Road; therefore, the presence of archaeological resources along Route Segment F and Mount Hope Bridge HDD Option 4 are unknown.
Visual	*Analysis of Visual Effects to Historic Properties* (COP, Appendix S; SouthCoast Wind 2024)	Historic Resource Visual Effects Assessment. Prepared by AECOM. Background research of known aboveground historic properties and TCPs in the visual APE for offshore and Onshore Project components in Falmouth, MA.	This report analyzed the effects of the Project on historic aboveground resources in the visual PAPE. The report determined that there were 11 historic aboveground resources, historic properties, and historic districts and three TCPs in the visual PAPE for Offshore Project components. The report also determined that there are two historic aboveground resources and historic properties for Onshore Project components in Falmouth, MA. The report recommended that two historic properties would experience an adverse effect as a result of the project: the Nantucket Historic District NHL and the Oak Grove Cemetery in Falmouth, MA.
Visual	*Analysis of Visual Effect to Historic Properties—Brayton Point* (COP, Appendix S.1; SouthCoast Wind 2024)	Historic Resource Visual Effects Assessment. Prepared by Tetra Tech. Visual effects analysis of aboveground historic properties (including known properties and a desktop analysis of potentially eligible properties) in the visual APE for Onshore Project components at Brayton Point in Somerset, MA.	This report analyzed the effects of the Project on historic aboveground resources in the visual PAPE for Onshore Project components at Brayton Point in Somerset, MA. A total of 11 previously identified historic aboveground resources, historic properties, and historic districts identified in this portion of the visual PAPE have potential views of the Onshore Project components. The report concluded that the Project would result in no adverse effect on all 11 properties.

HRG = high-resolution geophysical; PAPE = preliminary area of potential effects

I.2.2 Consultation and Coordination with the Parties and Public

I.2.2.1 Early Coordination

Since 2009, BOEM has coordinated OCS renewable energy activities offshore Massachusetts and Rhode Island with its federal, state, local, and Tribal government partners through its Intergovernmental Renewable Energy Task Force. In January 2019, Governor Christopher Sununu of the State of New Hampshire requested the establishment of an intergovernmental offshore wind renewable energy Task Force for the state. Given the regional nature of offshore wind energy development, BOEM has decided to establish a Gulf of Maine Task Force—including representation from New Hampshire, Massachusetts, Maine, and federally recognized Native American Tribes in the area. BOEM has met regularly with federally recognized Tribes that may be affected by renewable energy activities in the area, specifically during planning for the issuance of leases and review of site assessment activities. BOEM also hosts public information meetings to help keep interested stakeholders updated on major renewable energy milestones. Information pertaining to BOEM's Intergovernmental Renewable Energy Task Force meetings is available at https://www.boem.gov/renewable-energy/state-activities/renewable-energy-task-force-meetings. Information pertaining to BOEM's stakeholder engagement efforts in Massachusetts is available at https://www.boem.gov/renewable-energy/state-activities/massachusetts-activities. Information pertaining to BOEM's stakeholder engagement efforts in Rhode Island is available at https://www.boem.gov/renewable-energy/state-activities/rhode-island-activities. Information pertaining to the Gulf of Maine Task Force is available at: https://www.boem.gov/Gulf-of-Maine.

I.2.2.2 NEPA Scoping and Public Hearing

On November 1, 2021, BOEM announced its Notice of Intent (NOI) to prepare an EIS for the COP. The NOI commenced the public scoping process to identify issues and potential alternatives for consideration in the EIS. Throughout the scoping process, federal agencies; state, Tribal, and local governments; and the general public had the opportunity to help BOEM determine significant resources and issues, impact-producing factors, reasonable alternatives, and potential mitigation measures to be analyzed in the EIS, as well as provide additional information. BOEM also used the NEPA commenting process to allow for public involvement in the NHPA Section 106 consultation process (54 USC 300101 et seq.), as permitted by 36 CFR 800.2(d)(3). Through this notice, BOEM announced its intention to inform its NHPA Section 106 consultation using the NEPA commenting process and invited public comment and input regarding the identification of historic properties or potential effects on historic properties from activities associated with approval of the COP.

Additionally, BOEM held virtual public scoping meetings, which included specific opportunities for engaging on issues relative to NHPA Section 106 for the COP, on November 10, 15, and 18, 2021. Virtual public scoping meeting materials and records are available at https://www.boem.gov/renewable-energy/state-activities/southcoast-wind-virtual-meeting-room.

Through this NEPA scoping process, BOEM received comments related to cultural, historic, archaeological, or Tribal resources. These are presented in BOEM's EIS Scoping Report and are summarized as follows:

- Commenters asked that BOEM ensure compliance with Sections 106 and 110(f) of the NHPA as well as NEPA, including ensuring adequate consultation with consulting parties, SHPOs, Tribal Nations, National Historic Lighthouse and National Historic Lighthouse Preservation Act Lighthouse owners, and other stakeholders throughout the EIS process. Commenters also emphasized that BOEM must consider a wide range of potential effects on historic and cultural resources to ensure compliance with these laws, including visual impacts on NHLs.
- Commenters stated that BOEM should recognize Tribal Nations' sovereign status and provide adequate government-to-government consultation with Tribal governments throughout the EIS process.
- Commenters noted that the proposed Project would have an adverse visual impact on Nantucket's historic properties and cultural heritage, including the Nantucket Historic District, and requested that BOEM select an alternative that preserves the historic integrity of historic properties in Nantucket. Commenters also asked that BOEM consult with the Nantucket Historic District Commission, as well as Nantucket's historic and cultural review boards and stakeholders during any historic or archaeological review.
- Commenters felt that the VIA was not adequate and expressed concern over viewshed or visual impacts on historic properties from the proposed Project including impacts on Nantucket. Commenters requested that additional visual assessments be conducted including during different lighting and atmospheric conditions to accurately assess adverse impacts and to develop appropriate avoidance, minimization, and mitigation (AMM) measures. Other commenters asked for clarification regarding aspects of the VIA including the heights of the key observation points.
- Commenters identified specific historic properties to be identified in the APE for the cultural resources analysis including Nantucket Historic District NHL, Gay Head Light, Muskeget Island National Natural Landmark (NNL), Gay Head Cliff NNL. They also noted that all NHLs, National Historic Lighthouse Preservation Act Lighthouses, and NNLs should be identified on relevant Project maps.
- Commenters asked for Tribal Nations to be included in the development of the Marine Archaeological Resources Assessment and the Terrestrial Resources Assessment, as well as an Unanticipated (Post-Review) Discovery Plan and that the EIS provide an overview of BOEM and proponent engagement with Tribal Nations and a discussion of issues important to Tribal Nations.

On February 17, 2023, BOEM issued a Notice of Availability of the Draft EIS, initiating a 45-day public comment period from February 17 to April 3, 2023 (88 *Federal Register* 10377). BOEM held three virtual public hearings on March 20, March 22, and March 27, 2023. On April 4, 2023, BOEM announced a 15-day extension to the comment period, which concluded on April 18, 2023 (88 *Federal Register* 19986). Public comments were received through Regulations.gov on docket number BOEM-2023-0011, via email and through oral testimony at each of the three public hearings. BOEM received a total of 182 comment submissions from federal and state agencies, Tribal governments, local governments, non-governmental organizations, and the general public during the comment period. BOEM assessed and considered all the comments received in preparation of the Final EIS.

I.2.2.3 NHPA Section 106 Consultations

On September 29, 2021, BOEM contacted the Advisory Council on Historic Preservation (ACHP), MHC, and RIHPHC to provide Project information and notify these agencies of BOEM's intention to use the NEPA substitution process to fulfill Section 106 obligations under 36 CFR 800.8(c) in lieu of the procedures set forth in 36 CFR 800.3 through 800.6.

On September 29, 2021, BOEM contacted the Delaware Tribe of Indians, Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, Mohegan Tribe of Connecticut, The Delaware Nation, The Narragansett Indian Tribe, The Shinnecock Indian Nation, and Wampanoag Tribe of Gay Head (Aquinnah) with information about the Project, and an invitation to be a consulting party to the NHPA Section 106 review of the COP. BOEM also used this correspondence to notify of its intention to use the NEPA substitution process for Section 106 purposes, as described in 36 CFR 800.8(c), during its review. The following five Tribal Nations notified BOEM of their interest in participating as a consulting party: the Mashantucket (Western) Pequot Tribal Nation on October 19, 2021; Mashpee Wampanoag Tribe on October 6, 2021; The Narragansett Indian Tribe on November 1, 2021; The Shinnecock Indian Nation on February 4, 2022; and Wampanoag Tribe of Gay Head (Aquinnah) on November 1, 2021. The Delaware Tribe of Indians and Mohegan Tribe of Connecticut did not respond to BOEM's initiation of consultation; however, BOEM has included these Tribal Nations in all consulting party communications and considers them consulting parties. One Tribe, The Delaware Nation, declined the invitation to be a consulting party on October 13, 2021. BOEM requested information from Tribal consulting parties on sites of religious and cultural significance to the Tribal Nations that the proposed Project could affect, and BOEM offered its assistance in providing additional details and information on the proposed Project to the Tribal Nations.

From September 29 to October 7, 2021, BOEM corresponded with 88 points of contact from local, state, and federal government agencies and agencies and organizations due to the nature of their legal or economic relation to the undertaking or affected properties by mail and email, including information about the Project and an invitation to be a consulting party to the NHPA Section 106 review of the COP. BOEM also used this correspondence to notify of its intention to use the NEPA substitution process for Section 106 purposes, as described in 36 CFR 800.8(c), during its review. To aid those consulting parties not familiar with the NEPA substitution process, BOEM developed a *National Environmental Policy Act (NEPA) Substitution for Section 106 Consulting Party Guide* (available at https://www.boem.gov/sites/default/files/documents/renewable-energy/state-activities/NEPA-Substitution-Consulting-Party-Guide.pdf), which it attached to the correspondence.

On October 8, 2021, BOEM sent a Memorandum of Understanding (MOU) to the Delaware Tribe of Indians, Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, Mohegan Tribe of Connecticut, The Delaware Nation, The Narragansett Indian Tribe, The Shinnecock Indian Nation, and

Wampanoag Tribe of Gay Head (Aquinnah) to establish a cooperating Tribal government relationship with the purpose of preparing an EIS.

From October 13 to November 2, 2021, BOEM conducted outreach by phone to confirm receipt of correspondence among the governments and organizations that had not responded to the invitation to consult.

On October 26, 2021, BOEM corresponded with an additional six points of contact from governments and organizations by mail and email, to invite them to be consulting parties to the NHPA Section 106 review of the COP and provide the aforementioned NEPA substitution and Section 106 materials. On November 2, 2021, BOEM conducted outreach by phone to confirm receipt of correspondence among the additional points of contact from governments and organizations.

On November 1, 2021, BOEM contacted ACHP, MHC (the Massachusetts SHPO), the Rhode Island Historical Preservation & Heritage Commission (RIHPHC; the Rhode Island SHPO), and points of contact from consulting party governments and organizations by mail and email to notify all parties of the issuance the NOI to prepare an EIS consistent with NEPA regulations to assess the potential impacts of the Proposed Action and alternatives.

On November 2, 2021, BOEM contacted the Delaware Tribe of Indians, Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, Mohegan Tribe of Connecticut, The Narragansett Indian Tribe, The Delaware Nation, The Shinnecock Indian Nation, and Wampanoag Tribe of Gay Head (Aquinnah) by mail and email to notify the Tribal Nations of the issuance the NOI to prepare an EIS consistent with NEPA regulations to assess the potential impacts of the Proposed Action and alternatives.

On November 2, 2021, BOEM invited the Delaware Tribe of Indians, Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, Mohegan Tribe of Connecticut, The Delaware Nation, The Narragansett Indian Tribe, The Shinnecock Indian Nation, and Wampanoag Tribe of Gay Head (Aquinnah) to participate in a government-to-government consultation meeting. The email outreach also notified the Tribal Nations that public scoping meeting recordings and materials could be accessed via the virtual meeting website. On November 5, 2021, BOEM distributed an email reminder to consulting parties regarding the opportunity to participate in virtual public scoping meetings on November 10, November 15, and November 18, 2021.

From November 2 to November 18, 2021, BOEM corresponded with Tribal Nations who responded to the government-to-government consultation meeting invitation to schedule the meeting during a day and time of mutual availability.

BOEM invited Delaware Tribe of Indians, Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, Mohegan Tribe of Connecticut, The Delaware Nation, The Narragansett Indian Tribe, The Shinnecock Indian Nation, and Wampanoag Tribe of Gay Head (Aquinnah) to participate in a government-to-government consultation meeting on November 19, 2021.

On November 19, 2021, BOEM hosted a government-to-government consultation meeting with Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, and Wampanoag Tribe of Gay Head (Aquinnah). During the meeting, BOEM presented information about the NEPA/NHPA review process for offshore renewable energy projects, about the Project, and solicited input regarding reasonable alternatives for consideration in the EIS; the identification of historic properties or potential effects on historic properties from activities associated with the proposed Project; and potential measures to avoid, minimize, or mitigate impacts on environmental and cultural resources to be analyzed in the EIS.

On May 2, 2022, BOEM held a government-to-government meeting with the Chairwoman, Tribal Historic Preservation Officer (THPO), and Council members of the Wampanoag Tribe of Gay Head (Aquinnah). In the meeting, BOEM introduced and discussed the overall renewable energy program and process and summarized details and status of projects off the coast of New England. Topics identified for future discussion included cumulative visual simulations and resource impacts, the transmission process that is part of a lease, decommissioning process and oversight, proposed mitigation plans and agreements, and the Tribal capacity building initiatives.

On June 1, 2022, BOEM held a government-to-government meeting with the Chairwoman and Council members of the Wampanoag Tribe of Gay Head (Aquinnah). This meeting was a follow up to the May 2, 2022, meeting to continue the conversation on various topics and Tribal concerns related to offshore wind development off the New England coast collectively.

On June 2, 2022, the BOEM Director met in-person with the Mashpee Wampanoag Tribe to provide the Tribal Council with an overview of the current state of wind farm permitting off the coast of New England, including Gulf of Maine. Topics discussed during the meeting included the following: project and regional biological and economic concerns and potential mitigation strategies; cumulative visual impacts and simulations; and other programmatic topics, including transmission as part of a lease and capacity building initiatives.

From July 1 to July 8, 2022, BOEM corresponded with an additional three points of contact from governments and organizations by phone, mail, email, to invite them to be consulting parties to the NHPA Section 106 review of the COP and provide the aforementioned NEPA substitution and Section 106 materials.

On July 7, 2022, BOEM held virtual NHPA Section 106 Consultation Meeting #1. The presentation included a brief Project overview, review of NEPA substitution for the NHPA Section 106 process, overview of Section 106 consultation opportunities for the Project, NHPA Section 110(f) compliance requirements, and a question-and-answer session with discussion.

On September 1, 2022, BOEM held a government-to-government meeting with representatives from the Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, and Wampanoag Tribe of Gay Head (Aquinnah) to follow up on topics raised during NHPA Section 106 Consulting Meeting #1.

On February 2, 2023, BOEM shared with consulting parties drafts of the cultural resource technical reports prepared by SouthCoast Wind (Table I-3), the Cumulative Historic Resources Visual Effects Assessment (CHRVEA) (BOEM 2023), a technical memorandum detailing the delineation of the APE for the Project, this Finding of Adverse Effect, and the Draft MOA (Draft 1) for a 60-day comment period.

BOEM distributed a Notice of Availability to notify the consulting parties that the Draft EIS was available for public review and comment for a 45-day period commencing on February 17, 2023 (88 *Federal Register* 10377). BOEM held three virtual public hearings on March 20, March 22, and March 27, 2023. On April 3, 2023, BOEM notified consulting parties that the comment period for the Draft EIS and cultural resource technical reports and documents was extended to April 18, 2023. Public comments were received through Regulations.gov on docket number BOEM-2023-0011, via email and through oral testimony at each of the three public hearings. BOEM assessed and considered all the comments received and related to Section 106 consultation in preparation of the Final EIS.

On March 16, 2023, BOEM held virtual NHPA Section 106 Consultation Meeting #2. The presentation included a brief Project overview, an overview of BOEM's APE delineation, a review of the MARA, TARA, AVEHP, and CHRVEA reports, and a question-and-answer session with discussion.

On September 27, 2023, BOEM notified consulting parties that the Project required changes to the schedule for environmental review, which affected the Section 106 consultation schedule under NEPA substitution. BOEM informed consulting parties that project milestones on the Fast-41 permitting dashboard and the Section 106 consultation schedule would be updated when additional information is available about the project schedule.

On January 17, 2024, BOEM shared with consulting parties the revised cultural resource technical reports, Finding of Adverse Effect, and Draft MOA (Draft 2) for a 30-day comment period. At that time, BOEM also shared responses to NHPA Section 106 comments received on the Draft EIS and documents distributed to consulting parties on February 2, 2023.

On January 24, 2024, BOEM held virtual NHPA Section 106 Consultation Meeting #3. The presentation included an overview of Project updates, an overview of the revised technical reports, an overview of APE revisions, a summary of the revised Finding of Effect, and the Draft MOA (Draft 2), and solicited input on avoidance, minimization, mitigation, and monitoring measures to be stipulated in the MOA. The meeting also included a question-and-answer session with discussion.

On July 1, 2024, BOEM shared with consulting parties responses to comments received on documents distributed to consulting parties on January 17, 2024, and the revised cultural resource technical reports, Finding of Adverse Effect, and Draft MOA (Draft 3) for a 30-day comment period.

On July 15, 2024, BOEM held virtual NHPA Section 106 Consultation Meeting #4. The presentation included an overview of Project updates and its schedule, non-substantive revisions made to the cultural resource technical reports, the revised Finding of Adverse Effect, the Draft MOA (Draft 3), and a question-and-answer session with discussion.

On September 30, 2024, BOEM shared with consulting parties responses to comments received on documents distributed to consulting parties on July 1, 2024, and the revised Finding of Adverse Effect and Draft Final MOA (Draft 4) for a 30-day comment period.

On October 8, 2024, BOEM held virtual NHPA Section 106 Consultation Meeting #5. The presentation included an overview of Project updates and was held to consult on and finalize measures to avoid, minimize, and mitigate adverse effects on historic properties as stipulated in the MOA.

[Written in anticipation of Final MOA distribution and execution:] On November 19, 2024, BOEM distributed the Final MOA to signatories, Tribal Nations, and consulting parties for signature. Additional consultation meetings may be scheduled after publication of the Final EIS and prior to issuance of the ROD, if necessary, to resolve adverse effects via the MOA. Additional consultation will also occur for the process of phased identification and evaluation of historic properties to be completed in remaining unsurveyed portions of the terrestrial APE as stipulated in the MOA or if any alternatives that require phased identification are selected for the final Project design (Section I.5, *Phased Identification and Evaluation*). Simultaneous to the publication of the Final EIS, BOEM is coordinating with signatories to the MOA to have the MOA fully signed and executed by December 19, 2024 [anticipated]. The version of the MOA attached to this document as Attachment A is a draft of the MOA as of September 30, 2024 (Draft 4). The fully executed MOA will be posted on BOEM's website at https://www.boem.gov/renewable-energy/state-activities/southcoast-wind-formerly-mayflower-wind.

The list of Tribal Nations, governments, and organizations invited to participate as consulting parties is included in Attachment C. Entities that responded to BOEM's invitation or were subsequently made known to BOEM and added as consulting parties are listed in Attachment D.

I.3 Application of the Criteria of Adverse Effect

The Criteria of Adverse Effect under NHPA Section 106 (36 CFR 800.5(a)(1)) states that an undertaking has an adverse effect on a historic property if the following occurs:

> when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association…Adverse Effects may include reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance or be cumulative.

According to regulation, adverse effects on historic properties include, but are not limited to (36 CFR 800.5(a)(2)):

i. Physical destruction of or damage to all or part of the property;

ii. Alteration of a property, including restoration, rehabilitation, repair, maintenance, stabilization, hazardous material remediation, and provision of handicapped access, that is not consistent with the Secretary of the Interior's standards for the treatment of historic properties (36 CFR part 68) and applicable guidelines;

iii. Removal of the property from its historic location;

iv. Change of the character of the property’s use or of physical features within the property’s setting that contribute to its historic significance;

v. Introduction of visual, atmospheric, or audible elements that diminish the integrity of the property’s significant historic features;

vi. Neglect of a property that causes its deterioration, except where such neglect and deterioration are recognized qualities of a property of religious and cultural significance to an Indian tribe or Native Hawaiian organization; and

vii. Transfer, lease, or sale of property out of federal ownership or control without adequate and legally enforceable restrictions or conditions to ensure long-term preservation of the property’s historic significance.

I.3.1 Assessment of Effects on Historic Properties

This section documents the assessment of effects of the undertaking on historic properties in the marine, terrestrial, and visual APEs.

In addition to the assessment in the following subsections, Final EIS Chapter 3, Section 3.6.2, *Cultural Resources*, analyzes the impacts of the Proposed Action (the undertaking) on cultural resources identified in the APE. This analysis entails the assessment of the Proposed Action’s primary impact-producing factors (IPFs) determined relevant to cultural resources; these include accidental releases, anchoring, cable emplacement and maintenance, gear utilization, land disturbance, lighting, noise, and presence of structures. Unlike the other IPFs, accidental releases are considered a type of non-routine event, the occurrence of which is impossible to predict with certainty. Other non-routine events could include corrective maintenance activities; collisions involving vessels or vessels and marine life; allisions (a vessel striking a stationary object) involving vessels and WTGs or OSPs; cable displacement or damage by anchors or fishing gear; chemical spills or releases; severe weather and other natural events; fires; structural failures; and terrorist attacks. In the circumstance of an accidental release or other non-routine event that affects a historic property, BOEM would implement the process for responding to and consulting on an unanticipated effect as defined in the MOA stipulation for Post-Review Discoveries (Stipulation XI; refer to Section I.6, *Post-Review Discoveries and Unanticipated Effects*, for additional information). Refer to Attachment A for a draft of the MOA as of September 30, 2024.

BOEM has considered the primary IPFs for cultural resources in its assessment of the undertaking’s potential effects on historic properties as provided in the following subsections. Refer to Table I-4 for descriptions of these IPFs and summaries of BOEM’s conclusions as to how the Proposed Action’s IPFs may have impacts on cultural resources (refer to Final EIS, Section 3.6.2, *Cultural Resources*, for detailed analyses). BOEM has also considered the IPFs relevant to cultural resources in its assessment of the action alternatives identified during the NEPA review (i.e., Alternatives C, D, E, and F); refer to Section I.4.1, *Alternatives Considered*, for a summary of these alternatives and their potential effects on historic properties.

Table I-4. Primary IPFs and summary of impacts on cultural resources (from Final EIS, Chapter 3, Section 3.6.2, *Cultural Resources*)

IPF	Sources and Activities	Description	Impacts on Cultural Resources [a]
Accidental releases	• Mobile sources (e.g., vessels) • Installation, operation, and maintenance of onshore or offshore stationary sources (e.g., wind turbine generators, offshore substations, transmission lines, and interarray cables)	Refers to unanticipated releases or spills into receiving waters of a fluid or other substance, such as fuel, hazardous materials, suspended sediment, invasive species, trash, or debris. Accidental releases are distinct from routine discharges, consisting of authorized operational effluents, and they are restricted via treatment and monitoring systems and permit limitations.	Overall, localized, short term, and negligible to major depending on the number and scale of accidental releases. Although considered unlikely, large-scale accidental release and associated cleanup could result in temporary to permanent, geographically extensive, and large-scale major impacts.
Anchoring	• Anchoring of vessels • Attachment of a structure to the sea bottom by use of an anchor, mooring, or gravity-based weighted structure (i.e., bottom-founded structure)	Refers to seafloor disturbance (anything below Mean Higher High Water [MHHW]) related to any offshore construction or maintenance activities. Refers to an activity or action that disturbs or attaches objects to the seafloor.	Localized, permanent, and range from negligible to major impacts.
Cable emplacement and maintenance	• Dredging or trenching • Cable placement • Seabed profile alterations • Sediment deposition and burial • Cable protection of concrete mattress and rock placement	Refers to seafloor disturbances (anything below MHHW) related to the installation and maintenance of new offshore submarine cables. Cable placement methods include trenchless installation (such as HDD, direct pipe, and auger bore), jetting, vertical injection, control flow excavation, trenching, and plowing.	Localized, permanent, and range from negligible to major impacts.
Gear utilization	• Monitoring surveys	Refers to entanglement and bycatch during monitoring surveys.	Localized, permanent, and range from negligible to major impacts.
Land disturbance	• Vegetation clearance • Excavation • Grading • Placement of fill material	Refers to land disturbances during onshore construction activities.	Localized, range from short-term to permanent, and range from negligible to major impacts.

IPF	Sources and Activities	Description	Impacts on Cultural Resources [a]
Lighting	• Vessels or offshore structures above or under water • Onshore infrastructure	Refers to lighting associated with offshore wind development and activities that use offshore vessels, and that may produce light above the water onshore and offshore, as well as underwater. Refers to lighting associated with onshore Project infrastructure during construction and O&M, such as permanent lighting at O&M facilities.	Construction and decommissioning area lighting: localized, range from temporary to short-term, and negligible impacts. Operational lighting with use of ADLS: [b] negligible impacts.
Noise	• Aircraft • Vessels • Turbines • Geophysical (HRG surveys) and geotechnical surveys (drilling) • Construction equipment • Operations and maintenance • Onshore and offshore construction and installation • Vibratory and impact pile driving • Dredging and trenching • Unexploded ordnances (UXO) detonations	Refers to noise from various sources. Commonly associated with construction activities, geophysical and geotechnical surveys, and vessel traffic. May be impulsive (e.g., pile driving) or broad spectrum and continuous (e.g., from Project-associated marine transportation vessels and onshore substations). May also be noise generated from turbines themselves or interactions of the turbines with wind and waves.	Overall, negligible to moderate impacts.
Presence of structures	• Onshore structures including towers and transmission cable infrastructure • Offshore structures including WTGs, OSPs, and scour/cable protection	Refers to the post-construction, long-term presence of onshore or offshore structures.	Long-term, continuous, widespread, and moderate impacts.

[a] For the Proposed Action

[b] ADLS would be activated for less than 5 hours per year, or 0.1 percent of nighttime hours, compared to standard continuous Federal Aviation Administration hazard lighting (COP Appendix T, Section 5.1.3; SouthCoast Wind 2024).

Source: Final EIS, Chapter 3, Table 3.1-1, *Primary IPFs addressed in this analysis*, and Section 3.6.2, *Cultural Resources*.

I.3.1.1 Assessment of Effects on Historic Properties in the Marine APE

This section assesses effects on marine cultural resources (i.e., marine archaeological resources and ASLFs, including those affiliated with any TCPs) in the marine APE. Based on the information presented below, BOEM finds that historic properties would be adversely affected in the marine APE.

Marine Archaeological Resources

Marine geophysical archaeological surveys performed for the Proposed Action identified 50 magnetic anomalies, acoustic contacts, and buried reflectors representing potential marine archaeological resources (COP, Appendix Q; SouthCoast Wind 2024). Of this total, 46 resources are in the marine APE: five in the Lease Area, 16 in the Falmouth ECC, and 25 in the Brayton Point ECC. The remaining four other resources were identified outside the marine APE but reported for due diligence purposes; BOEM anticipates the Proposed Action will have no effect on these resources. Of the 46 resources in the marine APE, 32 resources were recommended to be historic properties potentially eligible for listing in the NRHP and are, therefore, considered for potential effects from the undertaking (Table I-4; COP, Appendix Q, SouthCoast Wind 2024). The remaining 14 marine archaeological resources likely relate to recent debris, industrial objects, and non-cultural geological features and therefore are not recommended to be historic properties; these are therefore not considered for potential effects from the Proposed Action. Table I-6lists the four resources outside of the marine APE and the 14 marine archaeological resources not recommended to be historic properties.

Table I-5. Potentially NRHP-eligible marine archaeological resources identified in the marine APE

Resource ID	Potential Source	Location	Location in Marine APE	Finding of Effect
Target 20-02	Unknown shipwreck	U.S. OCS	Lease Area	No effect (will be avoided)

Notes: Resources for which the finding of effect has been marked as "Not applicable" are those resources that have been recommended not eligible for listing in the NRHP.
Source: COP, Appendix Q; SouthCoast Wind 2024.
ID = identification

The severity of effects would depend on the extent to which integral or significant components of the affected marine archaeological resource are disturbed, damaged, or destroyed, resulting in the loss of contributing elements to the historic property's eligibility or potential eligibility for listing in the NRHP. Avoidance buffers for the marine archaeological resources that are historic properties in the marine APE are stipulated in the MOA as a result of consultations (Attachment A). The avoidance buffers for these historic properties were determined using several factors in a process developed by SouthCoast Wind's Qualified Marine Archaeologist (QMA). Those resources with a small visual footprint (i.e., <16.4 feet [<5 meters]) are to be protected by an avoidance buffer comprising a minimum 165-foot (50-meter) radius (84,539.54 ft^2 [7,853.98 $meters^2$]) extending from the target's centroid. Those with a larger visual footprint are to be protected by an avoidance buffer comprising a 164-foot (50-meter) buffer established off of all extant features, typically creating an ellipsoid or polygon-shaped avoidance area. Avoidance buffers recommended for each resource may contain contributing elements to the NRHP eligibility of the resources.

The SouthCoast Wind Project would avoid 31 of the 32 marine archaeological resources in the marine APE that are historic properties eligible for listing in the NRHP; therefore, the undertaking would have no effect on these resources. Measures to avoid the 31 marine archaeological resources, including specific avoidance buffers with which the Lessee is required to comply, are stipulated in the MOA. The SouthCoast Wind Project would not avoid the remaining marine archaeological resource (i.e., 21-01; Table I-5). As such, BOEM finds this marine archaeological resource would be subject to adverse effects from the undertaking. On September 27, 2024, the Lessee conducted a remotely operated vehicle (ROV) survey of marine archaeological resource 21-01. The ROV survey determined that marine archaeological resource 21-01 is in a high-energy, high-current environment and the historic property is currently buried just beneath the seafloor surface.

The MOA includes a stipulation requiring the Lessee to prepare a monitoring plan for marine archaeological resource 21-01 for the duration of the lease that will encompass construction, post-construction, and periodic inspections of the historic property. BOEM will use the procedures in MOA Stipulation VI (Review Process for Documents Produced Under MOA Stipulations) to consult with the signatories, Tribal Nations, and consulting parties on the monitoring plan. Refer to Table I-5 for BOEM's finding of effect for each marine archaeological resource in the marine APE and Attachment A for a draft of the MOA as of September 30, 2024.

Ancient Submerged Landform Features

ASLFs may be individually eligible for listing in the NRHP or considered contributing elements to a TCP eligible for listing in the NRHP. ASLFs in the marine APE are considered archaeologically sensitive. Although the marine geophysical remote-sensing studies performed to identify historic properties did not find direct evidence of pre-Contact Native American cultural materials, they represent a good-faith effort to identify submerged historic properties in the APE potentially affected by the undertaking, as defined at 36 CFR 800.4. If undiscovered archaeological resources are present within the identified ASLFs and they retain sufficient integrity, these resources could be eligible for listing in the NRHP under Criterion D. Furthermore, ASLFs are considered by Native American Tribes in the region to be culturally significant resources as the lands where their ancestors lived and as locations where events described in Tribal histories occurred prior to inundation. In addition, BOEM recognizes these landforms are similar to features previously determined to be TCPs and that are presumed to be eligible for listing in the NRHP under Criterion A.

SouthCoast Wind's marine geophysical archaeological surveys and geoarchaeological core processing identified 16 geomorphic features representing potential ASLFs (6). Of this total, nine are in the marine APE: one in the Lease Area, four in the Falmouth ECC, and four in the Brayton Point ECC (COP, Appendix Q; SouthCoast Wind 2024). The seven other identified ASLFs are below the maximum vertical extent of the marine APE; therefore, BOEM anticipates the Proposed Action will have no effect on these resources. In addition to the archaeological potential of ASLFs, a number of the identified landforms along the Falmouth ECC may be contributing elements to one or more TCPs, including the Nantucket Sound TCP (Section I.3.1.4, *Assessment of Effects on Historic Properties Located in Multiple Portions of the APE*). The extent of marine cultural investigations performed for the Proposed Action does not enable conclusive determinations of eligibility for listing identified resources in the NRHP; as such, all identified ASLFs are considered eligible for the purposes of this assessment and, therefore, historic properties. Additional archaeological surveys or analyses, if completed, may enable more refined assessments of integrity, significance, and eligibility for listing these resources in the NRHP.

Table I-7. ASLFs identified in SouthCoast Wind's investigations

Resource ID	Location	Location in Marine APE	Finding of Effect
LA-P-20-01	U.S. OCS	Lease Area	Adverse effect
FM-P-20-01	Massachusetts State	Outside marine APE (near Falmouth ECC)	No effect (outside APE)
FM-P-21-01A	Massachusetts State	Outside marine APE (near Falmouth ECC)	No effect (outside APE)
FM-P-21-01B	Massachusetts State	Outside marine APE (near Falmouth ECC)	No effect (outside APE)
FM-P-21-01C	Massachusetts State	Outside marine APE (near Falmouth ECC)	No effect (outside APE)
FM-P-21-02	Massachusetts State	Outside marine APE (near Falmouth ECC)	No effect (outside APE)
FM-P-21-03	Massachusetts State	Outside marine APE (near Falmouth ECC)	No effect (outside APE)
FM-P-21-04A	Massachusetts State	Falmouth ECC	No effect (will be avoided)
FM-P-21-04B	Massachusetts State	Falmouth ECC	No effect (will be avoided)
FM-P-21-05	Massachusetts State	Falmouth ECC	No effect (will be avoided)
FM-P-21-06	Massachusetts State	Outside marine APE (near Falmouth ECC)	No effect (outside APE)
FM-P-21-07	Massachusetts State	Falmouth ECC	No effect (will be avoided)
BP-P-21-01A	Massachusetts State	Brayton Point ECC	No effect (will be avoided)
BP-P-21-01B	Massachusetts State	Brayton Point ECC	No effect (will be avoided)
BP-P-21-02	Rhode Island State	Brayton Point ECC	Adverse effect
BP-P-21-03	Rhode Island State	Brayton Point ECC	No effect (will be avoided)

Source: COP, Appendix Q; SouthCoast Wind 2024.
ECC = export cable corridor; ID = identification.

The severity of effects would depend on the extent to which integral or significant components of the affected ASLF are disturbed, damaged, or destroyed, resulting in the loss of contributing elements to the historic property's eligibility for listing in the NRHP. Resource-specific minimum avoidance areas for ASLFs are stipulated in the MOA as a result of consultations (Attachment A).

SouthCoast Wind has presently committed to avoiding seven of the nine ASLFs in the marine APE, and therefore, the undertaking would have no effect on these resources. BOEM finds that two ASLFs would be subject to adverse effects from the undertaking. Mitigation measures to resolve adverse effects on these resources have been determined through consultations and are stipulated in the MOA. Refer to Table I-7 for BOEM's finding of effect for each ASLF and Attachment A for a draft of the MOA as of September 30, 2024.

Nantucket Sound TCP

SouthCoast Wind's cultural resource background research identified the Nantucket Sound TCP in and potentially affected by Project activities occurring in the marine APE (COP, Appendix Q; SouthCoast Wind 2024). However, this TCP was also identified in the visual APE for Offshore Project components (COP, Appendices S; SouthCoast Wind 2024). As such, BOEM's assessment of effects on this historic property can be found in Section I.3.1.4, *Assessment of Effects on Historic Properties Located in Multiple Portions of the APE*.

I.3.1.2 Assessment of Effects on Historic Properties in the Terrestrial APE

Cultural resource investigations completed for the Proposed Action identified historic properties in the terrestrial APE (COP, Appendix R; SouthCoast Wind 2024). Based on the information presented below, BOEM finds historic properties would be adversely affected in the terrestrial APE.

Terrestrial Archaeological Resources

As of November 2023, SouthCoast Wind's investigations have identified two terrestrial archaeological resources in the terrestrial APE (Table I-8; COP, Appendix R; SouthCoast Wind 2024), which are recommended to be eligible for listing in the NRHP under Criteria A and D, and BOEM is treating them as historic properties. Terrestrial archaeological investigations have not been fully completed in the terrestrial APE. As such, potential, presently undiscovered terrestrial archaeological resources may be present in the terrestrial APE and subject to adverse effects from the Proposed Action; these may be identified during SouthCoast Wind's process of phased identification and evaluation of historic properties (COP, Appendix R.2; SouthCoast Wind 2024; Section I.5, *Phased Identification and Evaluation*). The terrestrial APE also intersects the NRHP-listed Mount Hope Bridge boundary as defined by the U.S. National Park Service (NPS); further discussion of this historic property is provided in the *Historic Aboveground Resources* section below. BOEM anticipates that the number of identified terrestrial archaeological resources and historic properties in the terrestrial APE may be refined through the phased identification process and ongoing Section 106 consultations.

Table I-8. Terrestrial archaeological resources in the terrestrial APE

Resource ID	Cultural Component	Location in Terrestrial APE	Finding of Effect
RI-2816	Indeterminate pre-Contact Native American	Aquidneck Island, Portsmouth, Rhode Island	Adverse effect
RI-2817	Indeterminate pre-Contact Native American, possibly Transitional Archaic or Middle Woodland	Aquidneck Island, Portsmouth, Rhode Island	Adverse effect

Source: COP, Appendix R; SouthCoast Wind 2024.
APE = area of potential effect; ID = identification.

The severity of effects would depend on the extent to which integral or significant components of the affected terrestrial archaeological resource are disturbed, damaged, or destroyed, resulting in the loss of contributing elements to the historic property's eligibility for listing in the NRHP. Avoidance of the two known terrestrial archaeological resources has been recommended. If avoidance is not feasible, mitigation in the form of data recovery excavation in portions of the sites that cannot be avoided; installation of temporary site protective fencing prior to the start of construction; identifying the sensitive resource areas to construction work crews as areas where no ground-disturbing activities can take place; and archaeological construction monitoring has been recommended (COP, Appendix R; SouthCoast Wind 2024; MOA, Attachment 7). SouthCoast Wind has committed to monitoring during construction in areas determined to have a moderate to high potential for undiscovered archaeological resources (COP Volume 2, Table 16-1 and Appendix R.3; SouthCoast Wind 2024).

Phased identification as defined in 36 CFR 800.4(b)(2) will be used for the areas of the terrestrial APE identified in the Terrestrial Archaeology Phased Identification Plan (Attachment 12 of the MOA). Completion of Phase IB archaeological surveys during the phased identification process may lead to the identification of archaeological resources in the terrestrial APE. As such, the undertaking is currently anticipated to have adverse effects on the two known terrestrial archaeological resources identified in the terrestrial APE. The identification of other terrestrial archaeological resources in the terrestrial APE is possible in the completion of the phased identification process. BOEM will use the MOA to establish commitments for reviewing the sufficiency of any supplemental terrestrial archaeological investigations; assessing effects on historic properties; and implementing measures to avoid, minimize, or mitigate effects in these areas prior to construction. For additional details, refer to Section I.5, *Phased Identification and Evaluation*, and Attachment A for a draft of the MOA as of September 30, 2024.

Historic Aboveground Resources

One historic aboveground resource listed in the NRHP has been identified in the terrestrial APE: the Mount Hope Bridge (COP, Appendix R; SouthCoast Wind 2024). The terrestrial APE intersects the Mount Hope Bridge boundary as defined by NPS; however, the structure itself is not subject to physical adverse effects from the Proposed Action, and the Mount Hope Bridge has been determined to be significant and eligible for listing in the NRHP unrelated to potential archaeological elements. As such, BOEM determined the Project would have no effect on this historic property.

I.3.1.3 Assessment of Effects on Historic Properties in the Visual APE

Cultural resource investigations completed for the Proposed Action have identified historic properties in the visual APE (COP, Appendices S and S.1; SouthCoast Wind 2024). Based on the information presented below, BOEM finds historic properties would be adversely affected in the visual APE.

Review of the visual APE for Offshore Project components identified 11 historic aboveground resources and three TCPs (i.e., Chappaquiddick Island, Nantucket Sound, and Vineyard Sound and Moshup's Bridge) that would have views of the Project components. Review of the visual APE for Onshore Project components identified a total of 13 historic aboveground resources in Falmouth and Brayton Point, of which two would have views of the Onshore Project components in Falmouth. BOEM determined that four aboveground historic properties would experience adverse effects from the visibility of Project components (Table I-9).

The MOA stipulates that SouthCoast Wind will implement an Aircraft Detection Lighting System (ADLS) for aviation safety lighting on Offshore Project components (e.g., WTGs and OSPs). During operation of Offshore Project components, an ADLS would be activated for less than 5 hours per year, or 0.1 percent of nighttime hours, compared to standard continuous Federal Aviation Administration hazard lighting (COP Appendix T, Section 5.1.3; SouthCoast Wind 2024). When ADLS is not activated during construction and decommissioning, effects from lighting on Offshore Project components would be localized and range from temporary to short term. As a result, BOEM anticipates implementation of an ADLS will reduce nighttime visual effects on aboveground historic properties.

Table I-9. Adversely affected aboveground historic properties in the visual APE

Resource Name	Portion of Visual APE	Distance to Nearest WTG [a]	NRHP Status
Chappaquiddick Island TCP	Offshore Project components	30.8 miles	Eligible
Nantucket Historic District	Offshore Project components	23.4 miles	National Historic Landmark
Nantucket Sound TCP	Offshore Project components	25.1 miles	Eligible
Oak Grove Cemetery	Onshore Project components	N/A	Eligible

[a] For the Proposed Action.

Chappaquiddick Island TCP

Chappaquiddick Island TCP is located 30 miles (48.2 kilometers) north of the Lease Area at the eastern end of Martha's Vineyard. It is connected to the main island by a narrow barrier beach that is often breached by storms and winds (Epsilon Associates, Inc. 2020 as cited in the COP, Appendix S:3-10; SouthCoast Wind 2024). The landscape of this undeveloped island is largely scrub oak, pitch pines, oak trees, and red cedars that are up to approximately 20 feet (6.1 meters) tall (COP, Appendix S:3-10; SouthCoast Wind 2024).

The historic Chappaquiddick branch of the Wampanoag Tribe inhabited the island into the nineteenth century and currently are settled on a 100-acre (40-hectare) reservation within the island's brush land interior (Chappaquiddick Tribe, 2022, as cited in the COP, Appendix S:3-10; SouthCoast Wind 2024). In May and June 2019, the non-federally recognized historic Massachusetts Chappaquiddick Tribe of Wampanoag Nation notified BOEM of potential impacts on Chappaquiddick Island resulting from the Vineyard Wind project (BOEM 2019). As a result, Chappaquiddick Island was determined by BOEM to be potentially eligible for listing in the NRHP as a TCP.

Chappaquiddick Island TCP retains its maritime setting and continues to offer significant seaward views that support the integrity of this setting, which contributes to this resource's NRHP eligibility. Those seaward views include vantage points with the potential for an unobstructed view from contributing resources toward the Offshore Project components. Introduction of the WTGs and OSPs into the seascape horizon of the Chappaquiddick Island TCP would result in an adverse visual effect on the viewshed and maritime setting. Simulated conditions of the south shore of the island Wasque Point, Wasque Reservation, and Wasque Avenue Key Observation Points (KOP) revealed potential weak to moderate visual change to the island; the greatest visual change was found at the Wasque Avenue KOP (COP, Appendix S; SouthCoast Wind 2024). The intensity of the visual effect depends on blade movement, differing atmospheric conditions, and lighting. Based on this assessment, the introduction of Offshore Project components would result in a change to the unobstructed ocean viewshed of the TCP and would potentially compromise the setting of the TCP, which is a key character-defining feature. As a result, the Project would result in an adverse effect on the Chappaquiddick Island TCP.

As described in the *SouthCoast Wind Cumulative Historic Resources Visual Effects Analysis*, the Chappaquiddick Island TCP is 30.8 miles (49.6 kilometers) from the nearest WTG associated with the proposed Project and 14.7 miles (23.7 kilometers) from the nearest potential WTG location for other wind energy development activities. The total number of potentially visible WTGs is 679. Of these, 86 theoretically visible WTGs (12.66 percent) would be from the proposed Project. As such, BOEM determined the Project would add to the cumulative visual effects on the Chappaquiddick Island TCP when combined with the effects of other past, present, or reasonably foreseeable future actions (BOEM 2023).

Nantucket Historic District NHL

Nantucket Historic District is located 22.3 miles (35.9 kilometers) north of the Lease Area and encompasses Tuckernuck Island, Muskeget Island, and Nantucket Island. Nantucket Island is a well-preserved New England seaport, which retains intact buildings dating to the eighteenth and nineteenth centuries, when the whaling industry provided the primary source of commerce in the town. Economic decline on the island is largely responsible for the survival of excellent and intact architectural resources from the Colonial, Federal, Greek Revival, and Victorian periods. Preservation of these resources, and the island's location off the coast of Cape Cod, led to its significance as an early vacation resort. Tuckernuck Island contains a small collection of nineteenth and twentieth century buildings. Like Nantucket Island, this island is known for its nineteenth century architecture and benefited from the rise of the whaling industry. Muskeget Island contains only one building, a circa 1910 former Coast Guard boathouse, which is used as a summer residence. The Nantucket Historic District includes dense residential development from the era of whaling, residential development associated with tourism, grassy public parcels and lawns, undeveloped barren areas with grasslands, heathlands and salt marshes, scrub oak, deciduous trees, and barrens of pitch pine barrens that are up to 40 feet (12.2 meters) tall (COP, Appendix S:3-7; SouthCoast Wind 2024).

The Nantucket Historic District was determined to be an NHL and was listed in the NRHP in November 1966. In October 2012, the NHL nomination was updated and the historic district boundaries were expanded from just Nantucket Island to include Tuckernuck and Muskeget Islands. The district is significant under NRHP Criterion A/NHL Criterion 1 for its association with the whaling industry in New England; NRHP Criterion C/NHL Criterion 4 for the array of well-preserved resources reflecting a range of architectural styles and eras; and NRHP Criterion D for important cultural and historical data it has yielded or may yield. The period of significance begins in 1650 with the origination of the whaling industry, through the industry's demise in 1849, and spans to 1975 to include the period in which it emerged and thrived as a summer resort (Chase-Herrill and Pfeiffer 2012 as cited in COP, Appendix S:3-7; SouthCoast Wind 2024). Character-defining features of Nantucket Historic District include the collection of well-preserved buildings from Colonial, Federal, Greek Revival, and Victorian periods; the maritime setting of the district as an important whaling center with a high concentration of buildings, both simple and elaborate, oriented toward shorelines, harbors, and ocean vistas; and unobstructed views of the ocean from locations throughout the island. As a collection of resources that are united historically and aesthetically by plan and physical development, setting is an important character-defining feature of the historic district's integrity (COP, Appendix S:3-7; SouthCoast Wind 2024).

The Nantucket Historical Commission maintains a list of contributing and noncontributing resources within the district; this list contains 3,782 properties that are classified as either contributing, noncontributing, or some combination. Within the PAPE, there are 1,822 contributing properties are contributing, 1,108 noncontributing properties, and 852 properties that are either vacant or uncategorized (COP, Appendix S:3-7; SouthCoast Wind 2024).

Nantucket Historic District retains its maritime setting and continues to offer significant seaward views that support the integrity of this setting, which contributes to this resource's NRHP eligibility. Those seaward views include vantage points with the potential for an unobstructed view from contributing resources toward the Offshore Project components. Introduction of the WTGs and OSPs into the seascape horizon of the District would result in an adverse visual effect upon the viewshed and setting. Simulated conditions, particularly along the south shore of the island at historic locations, such as Tom Nevers Field and Miacomet Beach, revealed potential moderate visual change from some areas of the district, and moderate to major visual changes in other places, such as Cisco Beach and the Hummock Pond Road Bike Path. The intensity of the visual effect depends on blade movement, differing atmospheric conditions, and lighting. Based on this assessment, the introduction of Offshore Project components would result in a change to the unobstructed ocean viewshed of the district, would potentially compromise the setting of the district and its contributing resources, which is one of its key character-defining features. As a result, the Project would result in an adverse effect on Nantucket Historic District (COP, Appendix S:3-7-3-8; SouthCoast Wind 2024).

As described in the *SouthCoast Wind Cumulative Historic Resources Visual Effects Analysis*, the Nantucket Historic District is 23.4 miles (37.7 kilometers) from the nearest WTG associated with the proposed Project and 14.8 miles (23.8 kilometers) from the nearest potential WTG location for other wind energy development activities. The total number of potentially visible WTGs is 743. Of these, 129 theoretically visible WTGs (17.36 percent) would be from the proposed Project. As such, BOEM determined the Project would add to the cumulative visual effects on the Nantucket Historic District when combined with the effects of other past, present, or reasonably foreseeable future actions (BOEM 2023).

Nantucket Sound TCP

SouthCoast Wind's cultural resource background research identified the Nantucket Sound TCP in and potentially affected by Project activities occurring in the visual APE for Offshore Project components (COP, Appendix S; SouthCoast Wind 2024). However, this TCP was also identified in the marine APE (COP, Appendices Q; SouthCoast Wind 2024). As such, BOEM's assessment of effects on this historic property can be found in Section I.3.1.4, *Assessment of Effects on Historic Properties Located in Multiple Portions of the APE*.

Oak Grove Cemetery (Falmouth, Massachusetts)

The Oak Grove Cemetery was established circa 1850. It encompasses 18.9 acres and consists of 35 contributing resources. The landscape includes manicured lawns and native plantings under an open canopy of deciduous and evergreen trees that are up to 40 feet tall. The cemetery exhibits a mix of the ideals of the rural/garden cemetery movement and the more geometric configuration of formal nineteenth century community cemeteries. The Oak Grove Cemetery was determined to be eligible for listing in the NRHP in 2014. The cemetery is significant under Criterion A for its association with the history of the town of Falmouth and is the town's largest nineteenth century cemetery. It is also significant under Criterion C as a well-preserved local example of both a nineteenth century rural and formal cemetery. The period of significance of the resource area is 1850 to 1964. Character-defining features of the cemetery include the layout and landscape, greenspace, and myriad markers. As a cemetery that is significant for its association with the rural cemetery movement, which sought to create a pastoral park-like environment, the setting is an important characteristic feature of the resource (COP, Appendix S:3-22; SouthCoast Wind 2024).

The Oak Grove Cemetery retains its rural setting, which contributes to its NRHP eligibility. From the cemetery, views toward the Falmouth Onshore Project components would be possible. The Oak Grove Cemetery is located immediately approximately 0.1 mile west of the Lawrence Lynch substation site and 3.34 miles from the Cape Cod Aggregates Substation site. Distance, vegetation, and other buildings partially obstruct views of the Cape Cod Aggregates Substation site from the cemetery. Though there is some vegetation between the historic property and the Lawrence Lynch substation site, the historic property is immediately adjacent and would have a view of the substation building along its eastern edge. In addition, there is the potential for short-term, temporary auditory effects due to construction activities. As a rural, garden-style cemetery that was designed to provide a natural sanctuary for mourners, setting is a character-defining feature of its significance. The cemetery would experience a long-term visual change in setting due to the construction of the Lawrence Lynch substation. The introduction of a new, modern visual element has the potential to compromise the rural and contemplative setting, affecting its ability to convey significance. As a result, the Project would have an adverse effect on the Oak Grove Cemetery if the Falmouth ECC were used (COP, Appendix S:3-22; SouthCoast Wind 2024).

I.3.1.4 Assessment of Effects on Historic Properties Located in Multiple Portions of the APE

The historic property discussed in this section has been identified within multiple portions of the APE and, as such, is subject to both physical and visual effects.

Nantucket Sound TCP

In 2009, MHC determined Nantucket Sound was eligible for listing in the NRHP as a TCP under Criterion D in recognition of the high potential for preserved cultural areas (Simon 2009 as cited in the COP, Appendix Q:32; SouthCoast Wind 2024). Per Criterion D, Nantucket Sound was found to yield and have the potential to yield valuable information related to pre-Contact Cape Cod and its surrounding islands (NPS 1995, 2010 as cited in the COP, Appendix Q:44; SouthCoast Wind 2024). ASLFs identified through SouthCoast Wind's marine geophysical archaeological surveys within or in proximity to the Nantucket Sound may be contributing elements to the TCP's eligibility for listing in the NRHP.

By approximately 17,000 calibrated years Before Present (cal BP), the Laurentide Ice Sheet had retreated to the north shore of Cape Cod, and the southward draining braided streams deposited sediments on a glacial outwash plain. As the stream system migrated laterally south of the retreating ice front, glacial lakes along the coastal plain were buried beneath the prograding outwash. However, some glacial lakes may have drained southward into the Lease Area by way of water gaps between Nantucket and Martha's Vineyard before they were buried (Gutierrez et al. 2003 as cited in the COP, Appendix Q:31; SouthCoast Wind 2024). As late as 15,000 cal BP, the southern edge of the continental ice sheet still extended as far south as Cape Cod. At that time, sea stands were as much as 300 feet (91.5 meters) lower than present levels; now-inundated areas of the sea floor were exposed and potentially open to human habitation (Daley 2005 as cited in the COP, Appendix Q:31; SouthCoast Wind 2024). However, by cal 13,000 BP, as the climate moderated, most of southeastern New England was ice free (Raposa 2009 and Plymouth Archaeological Research Project [PARP] 2016 as cited in the COP, Appendix Q:31; SouthCoast Wind 2024). Sediment cores taken in Nantucket Sound in water depths of between 30 feet (9.1 meters) and 50 feet (15.2 meters) below mean sea level (MSL) demonstrated that the region surrounding Massachusetts' offshore islands once incorporated deciduous forests, wetlands, and swamps (Daley 2005 and Simon 2009 as cited in the COP, Appendix Q:31–32; SouthCoast Wind 2024).

Warming climatic conditions combined with isostatic rebound of the land mass resulted in rising sea levels that inundated exposed and potentially habitable landscapes (Bright et al. 2013:31 and Mahlstedt 2007a:24 as cited in the COP, Appendix Q:32; SouthCoast Wind 2024). Most of Nantucket Sound and the adjacent Vineyard Sound were submerged by 8,000 cal BP (Dunford 1999:43 as cited in the COP,

Appendix Q:32; SouthCoast Wind 2024). Despite this trend, the potential for intact early archaeological resources on or beneath the seafloor in this area is generally high.

A number of the ASLFs identified by SouthCoast Wind along the Falmouth ECC may be contributing elements to the Nantucket Sound TCP. The Falmouth ECC runs through Muskeget Channel into Nantucket Sound in Massachusetts state waters to make landfall in Falmouth, Massachusetts. SouthCoast Wind has presently committed to avoiding the four ASLFs located in the Falmouth ECC portion of the marine APE (i.e., FM-P-21-04A, FM-P-21-04B, FM-P-21-05, and FM-P-21-07) and therefore there would be no effect on these resources. As such, BOEM has concluded that the Project would not result in physical effects on ASLFs that are contributing elements to the Nantucket Sound TCP.

BOEM has concluded that the Project would result in an adverse *visual* effect on the Nantucket Sound TCP. In addition to being determined eligible under Criterion D, the TCP is significant under Criterion A and Criterion C. (COP, Appendix S:3-9; SouthCoast Wind 2024). Nantucket Sound TCP retains its maritime setting and continues to offer significant seaward views that support the integrity of this setting, which contributes to this resource's NRHP eligibility. Those seaward views include vantage points with the potential for an unobstructed view from contributing resources toward the Offshore Project components. As a result of the introduction of modern, intrusive elements associated with the Offshore Project components, the Nantucket Sound TCP would experience visual adverse effects.

As described in the *SouthCoast Wind Cumulative Historic Resources Visual Effects Analysis*, the Nantucket Sound TCP is 25.1 miles (40.4 kilometers) from the nearest WTG associated with the proposed Project and 14.3 miles (23.0 kilometers) from the nearest potential WTG location for other wind energy development activities. The total number of potentially visible WTGs is 744. Of these, 129 theoretically visible WTGs (17.33 percent) would be from the proposed Project. As such, BOEM determined the Project would incrementally add to the cumulative visual effects on the Chappaquiddick Island TCP when combined with the effects of other past, present, or reasonably foreseeable future actions (BOEM 2023).

I.3.2 Summary of Adversely Affected Historic Properties

I.3.2.1 Adverse Effects on Historic Properties in the Marine APE

The Project would have no adverse effect on 31 of 32 marine archaeological resources, and seven of nine ASLFs in the marine APE due to SouthCoast Wind's commitment to avoidance of these historic properties. However, the Project would have adverse effects on one marine archaeological resource and two ASLFs in the marine APE. Mitigation measures to resolve adverse effects on these resources will be determined through consultations and will be stipulated in the MOA. Refer to Attachment A for a draft of the MOA as of September 30, 2024.

I.3.2.2 Adverse Effects on Historic Properties in the Terrestrial APE

The Project would have adverse effects on known historic properties in the terrestrial APE: two terrestrial archaeological resources. Avoidance has been recommended for these two historic properties; avoidance of a historic property would result in no effect on the historic property. However, development of the final Project design is ongoing, and it is currently unclear whether SouthCoast Wind would be able to avoid adverse effects. If avoidance is not feasible, mitigation in the form of data recovery, excavation in portions of the sites that cannot be avoided; installation of temporary site protective fencing prior to the start of construction; identifying the sensitive resource areas to construction work crews as areas where no ground-disturbing activities can take place; and archaeological construction monitoring has been recommended (COP, Appendix R; SouthCoast Wind 2024). Therefore, BOEM has determined the undertaking would have adverse effects on historic properties in the terrestrial APE.

Additional terrestrial archaeological resources, of which all or some may be subject to adverse effects from the Project, may be identified during SouthCoast's process of phased identification and evaluation of historic properties as defined in 36 CFR 800.4(b)(2) (Section I.5, *Phased Identification and Evaluation*). BOEM has used the MOA to establish commitments for reviewing the sufficiency of any supplemental terrestrial archaeological investigations as phased identification; assessing effects on historic properties; and implementing measures to avoid, minimize, or mitigate effects in these areas prior to construction. Refer to Section I.5, *Phased Identification and Evaluation*, and Attachment A for a draft of the MOA as of September 30, 2024.

I.3.2.3 Adverse Effects on Historic Properties in the Visual APE

Based on the information BOEM has available from the studies conducted to identify historic properties in the visual APE of the Project and the assessment of effects upon those properties determined in consultation with consulting parties, BOEM has found that the Proposed Action would have direct visual adverse effects on a total of three aboveground historic properties, including one NHL (Nantucket Historic District) within the visual APE for Offshore Project components (Table I-9). BOEM determined that one historic property within the visual APE for Onshore Project components would be adversely affected if the variant Falmouth ECC is used. The undertaking would introduce visual elements that are out of character with the historic setting that contributes to the historic properties' significance. However, BOEM has determined that, due to the distance and open viewshed between the historic properties and affecting Project components, the integrity of the historic properties would not be so diminished as to *disqualify* any of them from NRHP eligibility. The adverse effects on the viewshed of the aboveground historic properties would occupy the space for approximately 35 years, but they are unavoidable for reasons discussed in Section I.3.1.3, *Assessment of Effects on Historic Properties in the Visual APE*. This application of the Criteria of Adverse Effect and determination that the effects are direct are based on pertinent NRHP bulletins, subsequent clarification and guidance by ACHP and NPS, and other documentation, including professionally prepared viewshed assessments and computer-simulated photographs.

Where BOEM determined adverse visual effects would occur from Offshore Project components on historic properties, BOEM then assessed whether those effects would add to the potential adverse effects of other reasonably foreseeable actions and thereby result in cumulative effects, which are additive effects. Where BOEM found visual adverse effects on historic properties in the visual APE for

Offshore Project components (Table I-9), BOEM also determined that the undertaking would contribute to cumulative adverse effects (BOEM 2023).

I.4 Actions to Avoid, Minimize, or Mitigate Adverse Effects

As a requirement of COP approval, BOEM developed avoidance, minimization, or mitigation, and monitoring measures that would be implemented to avoid and resolve adverse effects on historic properties, including cumulative visual adverse effects to which the Project would be additive. These measures were developed through consultations and would be implemented through the execution of the MOA by BOEM and the required signatories in accordance with the NHPA Section 106 regulations (36 CFR 800) and in compliance with Section 110(f). This process considers all prudent and feasible alternatives to avoid adverse effects as discussed in Section I.4.1, *Alternatives Considered*, and included, to the maximum extent possible, taking such planning actions as may be necessary to minimize harm to any NHL that may be directly and adversely affected by an undertaking.

Simultaneous to the publication of the final EIS, BOEM will coordinate with signatories to the MOA to have the MOA fully signed and executed by December 19, 2024. The version of the MOA attached to this document as Attachment A is a draft of the MOA as of September 30, 2024. The fully executed MOA will be posted on BOEM's website at: https://www.boem.gov/renewable-energy/state-activities/southcoast-wind-formerly-mayflower-wind.

I.4.1 Alternatives Considered

BOEM's election to use NEPA substitution for the Section 106 review of the Project included the identification and evaluation of historic properties for the undertaking and assessment of effects for all the action alternatives identified during the NEPA review. BOEM's NEPA EIS and Section 106 reviews have analyzed six action alternatives (i.e., A through F; Table I-10) for impacts on cultural resources (Final EIS, Chapter 3, Section 3.6.2, *Cultural Resources*) and effects on historic properties as presented in this section. Table I-10also denotes Alternative D as BOEM's Preferred Alternative as identified in the Final EIS. Additional details on the action alternatives and Preferred Alternative can be found in Chapter 2 of the Final EIS.

Table I-10. Summary of alternatives analyzed in the Final EIS and Section 106 review

Alternative	Description
Alternative A – No Action Alternative	Under Alternative A, BOEM would not approve the COP, and the Project's construction and installation, operations and maintenance, and eventual decommissioning would not occur, and no additional permits or authorizations for the Project would be required. Any potential environmental and socioeconomic impacts, including benefits, associated with the Project as described under the Proposed Action would not occur. However, all other existing or other reasonably foreseeable future impact-producing activities would continue. The impact of the No Action Alternative serves as the baseline against which all action alternatives are evaluated.

Alternative	Description
Alternative B – Proposed Action	Under Alternative B, the construction, operations and maintenance, and conceptual decommissioning of the Project on the OCS offshore of Massachusetts would occur within the range of design parameters outlined in the SouthCoast Offshore Wind COP (SouthCoast Wind 2024), subject to applicable mitigation measures. The Project would have a capacity of up to 2,400 MW and would consist of up to 147 WTGs in the Lease Area, up to 5 OSPs and associated export cables. SouthCoast Wind would space WTGs in a 1-by-1-nautical-mile offset grid pattern (east–west-by-north–south-gridded layout). The Project would include one preferred ECC making landfall and interconnecting to the power grid at Brayton Point, in Somerset, Massachusetts, and one variant ECC making landfall and interconnecting to the power grid in Falmouth, Massachusetts. The ECC to Brayton Point would have an intermediate landfall on Aquidneck Island, Rhode Island.
Alternative C – Fisheries Habitat Impact Minimization	Under Alternative C, the construction, operations and maintenance, and eventual decommissioning of the Project on the OCS offshore Massachusetts would occur within the range of the design parameters outlined in the SouthCoast Wind COP, subject to applicable mitigation measures. However, the Project would include an onshore export cable route that would avoid placing the offshore export cable in the Sakonnet River to avoid impacts on fisheries habitats. Alternative C includes two possible onshore export cable routes. • Alternative C-1: Aquidneck Island, Rhode Island Route • Alternative C-2: Little Compton/Tiverton, Rhode Island Route
Alternative D – Nantucket Shoals (Preferred Alternative)	Under Alternative D, the construction, operations and maintenance, and eventual decommissioning of the Project on the OCS offshore Massachusetts would occur within the range of the design parameters outlined in the SouthCoast Wind COP, subject to applicable mitigation measures. However, up to 6 WTGs (AZ-47, BA-47, BB-47, BC-47, BC-48, and BF-49) would be eliminated in the northeastern portion of the Lease Area to reduce potential impacts on foraging habitat and potential displacement of wildlife from this habitat adjacent to Nantucket Shoals.
Alternative E – Foundation Structures	Under Alternative E, the construction and installation, operations and maintenance, and eventual decommissioning of the Project on the OCS offshore Massachusetts would occur within the range of the design parameters, which includes a range of foundation types (monopile, piled jacket, suction bucket, and gravity based), subject to applicable mitigation measures. This alternative includes three foundation options, which assume the maximum use of piled (monopile and piled jacket), suction bucket, and gravity-based foundation structures to assess the extent of potential impacts from each foundation type. • Alternative E-1: Piled Foundations (monopile and piled jacket) only • Alternative E-2: Suction Bucket Foundations only • Alternative E-3: Gravity-based Foundations only
Alternative F – Muskeget Channel Cable Modification	Under Alternative F, the construction, operations and maintenance, and eventual decommissioning of the Project on the OCS offshore Massachusetts would occur within the range of the design parameters outlined in the SouthCoast Wind COP, subject to applicable mitigation measures. However, to minimize seabed disturbance in the Muskeget Channel, the Falmouth offshore export cable route would use ±525kV HVDC cables connected to an HVDC converter station, instead of HVAC cables connected to offshore substations, and would only use up to 3 offshore export cables, instead of up to 5 offshore export cables.

I.4.1.1 Action Alternatives that Would Minimize the Adverse Effect of the Project

While some of the action alternatives and sub-alternatives identified for the Project may avoid, minimize, or mitigate adverse effects on some historic properties, no alternative that meets the purpose and need of Project development in the Lease Area would fully avoid adverse effects on historic properties, including visual effects on NHLs. BOEM's Preferred Alternative (Alternative D) would include up to six fewer WTGs (Table I-10). The Preferred Alternative is unlikely to lessen physical impacts on historic properties, and while it would reduce the number of Project components contributing to visual effects on historic properties, the number of eliminated WTGs is not anticipated to result in a substantial minimization of visual adverse effects. Overall, the adoption of the Preferred Alternative (Alternative D) would result in the same adverse effects on historic properties as the Proposed Action.

The following sections compare the other action alternatives to the Proposed Action and discuss which would avoid or minimize the adverse effect of the Project on historic properties. Additionally, as described in Section I.3.1, BOEM has considered the primary IPFs relevant to cultural resources (i.e., accidental releases, anchoring, cable emplacement and maintenance, gear utilization, land disturbance, lighting, noise, and presence of structures) in its assessment of the action alternatives' potential effects on historic properties as provided in the following subsections. Refer to Chapter 3, Section 3.6.2, *Cultural Resources,* of the Final EIS for additional details on each alternative as is applicable to cultural resources and historic properties and for NEPA analyses of the potential impacts of these alternatives on cultural resources, including BOEM's Preferred Alternative.

Minimization of Physical Effects on Historic Properties

The Proposed Action (Alternative B) is anticipated to have physical adverse effects on historic properties. Specifically, these include one marine archaeological resource, two ASLFs, and one TCP (i.e., the Nantucket Sound TCP) in the marine APE; and two terrestrial archaeological resources in the terrestrial APE.

Alternatives C, D, E, and F all involve a potential reduction in number or size of Offshore Project components that would be built for the Project, thereby reducing potential seabed-disturbing activities that could cause physical adverse effects on historic properties. The reduction in number or size of WTGs, OSPs, interlink cables, and export cables may minimize effects on one marine archaeological resource, two ASLFs, and one TCP depending on the locations of the removed components in relation to the specific locations of these historic properties. The marine archaeological resource and the ASLFs located within the area from which Offshore Project components would be removed would experience no or minimized effects from the Project. Additionally, removal of Offshore Project components under these alternatives would minimize potential physical adverse effects on presently undiscovered marine archaeological resources in these areas. However, while these alternatives may minimize adverse effects on some specific historic properties, they may also introduce adverse effects on others. A discussion of each alternative and sub-alternative is provided below.

Alternative C includes two sub-alternatives (C-1 and C-2) to analyze alternate onshore cable route options developed to avoid installation of a portion of the proposed Brayton Point Offshore Export Cable that runs through the Sakonnet River (Figure I.B-15). Alternative C-1 includes a western and eastern onshore route variation on Aquidneck Island, Rhode Island.

Alternative C-1 (Aquidneck Island, Rhode Island Route) would result in full avoidance of adverse effects on one ASLF (i.e., BP-P-21-02) that is a historic property potentially eligible for listing in the NRHP. Alternative C-2 (Little Compton/Tiverton, Rhode Island Route) would also result in full avoidance of adverse effects on one ASLF (i.e., BP-P-21-02). BOEM would require SouthCoast Wind to uphold the same applicable commitments to avoid specific marine cultural resources should this alternative be adopted (refer to Attachment A for a draft of the MOA as of September 30, 2024). However, either sub-alternative may introduce adverse effects on currently unidentified but potential historic properties that may be present within a potential offshore ECC that would encompass this alternate route.

Additionally, for the Alternative C-1 cable route option overall, background research identified a total of 10 known terrestrial archaeological resources and 21 known historic aboveground resources, including six historic properties listed in the NRHP and six historic cemeteries (Table I-11; PAL 2022).[1] One of the terrestrial archaeological resources (RI-1587, Fairview Site) has been previously recommended not eligible for listing in the NRHP; however, because it is the only resource with such a recommendation, BOEM has included consideration of this resource in discussion here for the purposes of NHPA consultation. Adoption of Alternative C-1 using the western route variation would have potential adverse effects on nine terrestrial archaeological resources and 18 historic aboveground resources, including five historic properties listed in the NRHP and five historic cemeteries (PAL 2022). Adoption of Alternative C-1 using the eastern route variation would have potential adverse effects on seven known terrestrial archaeological resources and 15 known historic aboveground resources, including three historic properties listed in the NRHP and four historic cemeteries (PAL 2022). For Alternative C-2, background research identified three known terrestrial archaeological resources and 23 known historic aboveground resources, including four historic properties listed in the NRHP and eight historic cemeteries, that have the potential to be subject to adverse effects (Table I-12; PAL 2022). Overall, BOEM finds Alternative C is unlikely to minimize adverse effects on historic properties.

Table I-11. Cultural resources and historic properties subject to potential adverse effects from adoption of Alternative C-1 and its route variations

Resource ID or Name	Resource Type	NRHP Status	Alt. C-1 Route	
			West Variation	East Variation
Bailey Farm	Historic above.	Listed	X	
Boyd's Windmill	Historic above.	Listed	X	

[1] Rhode Island General Law [RIGL] 23-18-11 et seq. (State Cemeteries Act) conditionally prohibits any town or city from permitting "construction, excavation or other ground disturbing activity within twenty-five (25) feet of a recorded historic cemetery" unless the "boundaries of the cemetery are adequately documented and there is no reason to believe additional graves exist outside the recorded cemetery." As such, BOEM assumes historic cemeteries within 25 feet (7.6 meters) of the Project would be subject to adverse impacts without the adoption of AMMs.

Alternative D would involve elimination of six WTGs in the northeastern portion of the Lease Area. No known marine cultural resources are located in the area from which WTGs would be eliminated. However, removal of these Offshore Project components would reduce potential impacts on currently undiscovered marine archaeological resources that may be present in these areas. In general, Alternative D is unlikely to minimize physical adverse effects on historic properties.

Alternative E includes three sub-alternatives (E-1, E-2, and E-3) to analyze the maximum design scenario for each of the three different foundation categories that could be used for WTGs and OSPs. Alternative E-1 involves the use of piled foundations for all WTGs and OSPs. Alternative E-2 involves the use of suction-bucket foundations for all WTGs and OSPs. Lastly, Alternative E-3 involves the use of gravity-based foundations for all WTGs and OSPs. Effects on marine archaeological resources and ASLFs may be reduced, the same, similar, or increased compared to those under the Proposed Action depending on the final foundation type(s) selected under the Proposed Action and specific locations of marine archaeological resources and ASLFs in relation to proposed WTGs and OSPs. The severity of effects on these historic properties increases with the size of the foundation type and anticipated seabed disturbance. However, overall, the nature and physical extent of proposed activities under this alternative would be largely comparable to those of the Proposed Action.

Alternative F would limit the number of cables installed in the Falmouth offshore export cable route to three, as opposed to five under the Proposed Action. Reduction of the number of installed cables would reduce the overall area subject to potential seabed disturbance, thereby minimizing potential adverse effects on marine cultural resources located within the Falmouth offshore ECC, including the Nantucket Sound TCP and any ASLFs that may be contributing elements to the TCP. BOEM would require SouthCoast Wind to uphold the same applicable commitments to avoid marine archaeological resources and ASLFs located in the Falmouth Offshore ECC should this alternative be adopted (refer to Table I-5 and Table I-7 for information on these specific commitments and Attachment A for a draft of the MOA as of September 30, 2024). However, any historic properties for which there are no commitments to avoidance from SouthCoast Wind still be subject to physical adverse effects.

Overall, the potential reduced scale of Alternatives C, D, E, and F may minimize physical adverse effects on historic properties. However, the majority of historic properties subject to effect under the Proposed Action are located in other areas of the marine APE that are unchanged under Alternatives C, D, E, and F. As a result, these alternatives may reduce adverse effects on specific individual historic properties but would not avoid or substantially minimize adverse effects on historic properties in general. Because of all these factors, the only alternative that BOEM was able to identify that avoids any Project effects on these historic properties was the No Action Alternative.

Minimization of Visual and Cumulative Visual Effects on Historic Properties

The Proposed Action (Alternative B) is anticipated to have visual adverse effects on historic properties. Specifically, these are three historic aboveground resources, including one NHL, in the visual APE for Offshore Project components and one historic aboveground resource in the visual APE for Onshore Project components. A discussion specific to NHLs is provided in *National Historic Landmarks*.

Of all alternatives, only Alternative D involves the reduction in Project components that would reduce Project visibility that could cause visual adverse effects on historic properties. Alternative D would involve elimination of 6 WTGs in the northeastern portion of the Lease Area. However, the number of eliminated WTGs is not anticipated to result in a substantial minimization of visual adverse effects. As a result, BOEM determined that all feasible alternatives, including all feasible WTG layouts, would result in visual adverse effects on aboveground historic properties. Because of all these factors, the only alternative that BOEM was able to identify that avoids any Project effects on these historic properties was the No Action Alternative.

Contributing to the potential 901 WTGs modeled in a maximum-case scenario for other future offshore wind activities, all the action alternatives (B through F) would result in visual adverse effects from offshore WTG structure visibility and lighting, including from navigational and aviation hazard lighting systems. Due to cumulative effects from other offshore wind activities, the same three historic properties in the visual APE for Offshore Project components would continue to be adversely affected by offshore structure and lighting visibility under Alternatives C through F as under the Proposed Action. The cumulative visual effects and lighting on historic properties in the visual APE associated with Alternatives C through F, when combined with past, present, and reasonably foreseeable activities, would be long-term and adverse, until decommissioning of the Project.

National Historic Landmarks

The implementing regulations for Section 106 of the NHPA at 36 CFR 800.10 provide special requirements for protecting NHLs and complying with the NHPA Section 110(f). NHPA Section 110(f) applies specifically to NHLs. NPS, which administers the NHL program for the Secretary of the Interior, describes NHLs and requirements for NHLs as follows:

> National Historic Landmarks (NHL) are designated by the Secretary under the authority of the Historic Sites Act of 1935, which authorizes the Secretary to identify historic and archaeological sites, buildings, and objects which “possess exceptional value as commemorating or illustrating the history of the United States” Section 110(f) of the NHPA requires that Federal agencies exercise a higher standard of care when considering undertakings that may directly and adversely affect NHLs. The law requires that agencies, “to the maximum extent possible, undertake such planning and actions as may be necessary to minimize harm to such landmark.” In those cases when an agency’s undertaking directly and adversely affects an NHL, or when Federal permits, licenses, grants, and other programs and projects under its jurisdiction or carried out by a state or local government pursuant to a Federal delegation or approval so affect an NHL, the agency should consider all prudent and feasible alternatives to avoid an adverse effect on the NHL.

BOEM is implementing the special set of requirements for protecting NHLs and for compliance with NHPA Section 110(f) at 36 CFR 800.10, which, in summary:

- Requires the agency official, to the maximum extent possible, to undertake such planning and actions as may be necessary to minimize harm to any NHL that may be directly and adversely affected by an undertaking;
- Requires the agency official to request the participation of ACHP in any consultation conducted under 36 CFR 800.6 to resolve adverse effects on NHLs; and
- Further directs the agency to notify the Secretary of the Interior of any consultation involving an NHL and to invite the Secretary of the Interior to participate in consultation where there may be an adverse effect.

BOEM has planned, and is, taking action to avoid adverse effects on NHLs in accordance with NHPA 110(f) and pursuant to *The Secretary of the Interior's Standards and Guidelines for Federal Agency Historic Preservation Programs Pursuant to the National Historic Preservation Act* (NPS 2021). BOEM has determined that one NHL, the Nantucket Historic District, would be visually adversely affected by the Proposed Action. BOEM has notified NPS (as the delegate of the Secretary of the Interior) and the ACHP of this determination with distribution of this Finding. ACHP and NPS have been active consulting parties on the Project since BOEM invited them to consult at the initiation of the NHPA Section 106 process on the Project beginning on September 29, 2021. BOEM is fulfilling its responsibilities to give a higher level of consideration to minimizing harm to NHLs, as required by NHPA Section 110(f), through implementation of the special requirements outlined at 36 CFR 800.10.

In the Final EIS and as described herein (Table 1-9), BOEM has identified one alternative that reduces the number of WTGs from the maximum-case scenario of the Proposed Action (i.e., Alternative D). This alternative would reduce the visibility of the Project from the NHL. However, BOEM has determined that the Nantucket Historic District would still be adversely affected by the Project given the size, location, and number of proposed WTGs and distance of the Wind Farm Area to the shoreline under this alternative. As a result, BOEM determined that all feasible alternatives would result in visual adverse effects on this NHL. The only alternative that BOEM was able to identify that avoids any Project effects on this NHL was the No Action Alternative.

When prudent and feasible alternatives "appear to require undue cost or to compromise the undertaking's goals and objectives, the agency must balance those goals and objectives with the intent of section 110(f)" (NPS 2021). In this balancing, the NPS suggests that agencies should consider "(1) the magnitude of the undertaking's harm to the historical, archaeological and cultural qualities of the NHL; (2) the public interest in the NHL and in the undertaking as proposed, and (3) the effect a mitigation action would have on meeting the goals and objectives of the undertaking" (NPS 2021). For the Project, the magnitude of the visual effects on the Nantucket Historic District would be minimized by the distance between proposed offshore WTGs and NHL and through environmental factors, including weather and atmospheric conditions, that limit views of the Project WTGs from the NHL. Moreover, while the undertaking would affect the maritime setting of the NHL, it would not affect other character-defining features or aspects of the NHL's integrity. The Nantucket Historic District, should the undertaking proceed, would still illustrate its regional and national significance, and continue to exemplify its national importance.

Through consultation, BOEM refined the minimization measures to the maximum extent feasible and further developed mitigation measures to resolve adverse effects that remain at the Nantucket Historic District after the application of minimization efforts. BOEM has identified and is finalizing mitigation measures specific to the NHL with the consulting parties through development of the MOA (refer to Attachment A for a draft of the MOA as of September 30, 2024). Mitigation measures for adverse effects on the NHL must be reasonable in cost and not be determined using inflexible criteria, as described by the NPS (2021). Mitigation of adverse effects on the NHL meet the following requirements.

- Reflect the heightened, national importance of the property and be appropriate in magnitude, extent, nature, and location of the adverse effect.
- Focus on replacing lost historic resource values with outcomes that are in the public interest, such as through development of products that convey the important history of the property.
- Comply with *The Secretary of the Interior's Standards for the Treatment of Historic Properties with Guidelines for Preserving, Rehabilitating, Restoring and Reconstructing Historic Buildings* (NPS 2017).

I.4.2 Avoidance, Minimization, and Mitigation Measures

BOEM is consulting with Tribal Nations, SHPOs, ACHP, and consulting parties to finalize avoidance, minimization, mitigation, and monitoring measures for addressing the Project's adverse effects on historic properties. Specifically, BOEM's consultation has developed measures to avoid physical effects and minimize visual effects on historic properties in the APE. BOEM has also consulted on mitigation measures that would be triggered in cases where avoidance of adverse effects on historic properties is not feasible.

The NHPA Section 106 consultation process will culminate in an MOA detailing avoidance, minimization, mitigation, and monitoring measures to avoid and resolve adverse effects on historic properties, including cumulative visual adverse effects to which the Project would be additive. These measures will be stipulated in the MOA and summarized in Final EIS Appendix G, *Mitigation and Monitoring*. Attachment A is a draft of the MOA as of September 30, 2024.

I.5 Phased Identification and Evaluation

In consultation with BOEM and the relevant SHPO, SouthCoast Wind will be using a process of phased identification and evaluation of historic properties as defined in 36 CFR 800.4(b)(2). This includes any remaining unsurveyed areas of the terrestrial APE that would require phased identification of historic properties.

SouthCoast Wind has developed a plan for the process of completing additional required cultural resource investigations (refer to Attachment A for a draft of the MOA as of September 30, 2024; Attachment 12 of the MOA is the *Terrestrial Archaeology Phased Identification Plan*). As of September 2024, efforts to identify and evaluate terrestrial archaeological resources in the terrestrial APE have encompassed areas proposed for Onshore Project components in Massachusetts and Rhode Island. However, the identification and evaluation of historic properties for the entire terrestrial APE is incomplete. Additional archaeological surveys conducted during the phased process may lead to the identification of additional archaeological resources and historic properties in the terrestrial APE. Additionally, if any Project alternatives are approved or there are any changes to the current Project design for either onshore or Offshore Project components that result in Project components falling outside of the previously assessed APE, updated technical studies and reports will be required. While updated information regarding the identification of historic properties was obtained after publication of the Draft EIS and is presented in the Final EIS, additional information may not be available until after the Final EIS.

Information pertaining to identification of historic properties for some Project alternatives may not be available until after the ROD is issued and the COP is approved. For Alternative C, if either sub-alternative (i.e., C-1 and C-2) is selected, BOEM will use the MOA to establish commitments for phasing identification and evaluation of historic properties in the APE, amending the APE, assessing effects, and resolving adverse effects prior to construction. If Alternative C-1 is selected, previously unsurveyed areas associated with the use of a cable route located west of the Sakonnet River would need to be surveyed for marine cultural resources, terrestrial archaeological resources, and historic aboveground resources. If Alternative C-2 is selected, previously unsurveyed areas associated with the use of a cable route located east of the Sakonnet River would need to be surveyed for marine cultural resources, terrestrial archaeological resources, and historic aboveground resources. The approach for phased identification and evaluation will be in accordance with BOEM's existing *Guidelines for Providing Archaeological and Historic Property Information Pursuant to Title 30 Code of Federal Regulations Part 585* and ensure potential historic properties are identified, effects are assessed, and adverse effects are resolved prior to construction.

BOEM has used the MOA to establish commitments for reviewing the sufficiency of any supplemental terrestrial archaeological investigations as phased identification and evaluation of historic properties in the APE; amending the APE per the final Project design, as necessary; and assessing and consulting on effects on historic properties (refer to Attachment A for a draft of the MOA as of September 30, 2024; Stipulation IV provides the protocol for implementing the process of phased identification and evaluation of historic properties). Simultaneous to the publication of the Final EIS, BOEM is coordinating with signatories to the MOA to have the MOA fully signed and executed by December 19, 2024.

I.6 Post-Review Discoveries and Unanticipated Effects

Despite sufficient completion of marine and terrestrial archaeological resource identification surveys, it is possible that unanticipated marine or terrestrial archaeological resources are encountered after BOEM's NHPA Section 106 review is complete and during construction, O&M, or decommissioning of the Project. Non-routine events also could result in an unanticipated effect on a historic property. BOEM has developed a protocol for cases in which there is either the unanticipated discovery of a previously unidentified historic property or an unanticipated effect on a known historic property, both of which are considered to be post-review discoveries. *The Post-Review Discoveries* stipulation of the MOA (Stipulation XI) provides the process for consultations, stabilization of the discovery location, additional investigations, and implementation of resolution measures in the case of a post-review discovery. Attachments 13 and 14 of the MOA are the Post-Review Discoveries Plans (PRDPs; also known as Unanticipated Discoveries Plans [UDPs]) describing the specific processes that would be followed in the case of an unanticipated, post-review discovery of a marine or terrestrial archaeological resource, respectively. Refer to Attachment A for a draft of the MOA as of September 30, 2024.

J.1.4 Chapter 4, Other Required Impact Analysis

None.

Appendix K: Glossary

Term	Definition
affected environment	Environment as it exists today that could be potentially affected by the proposed Project
algal blooms	Rapid growth of the population of algae, also known as *algae bloom*
allision	A moving ship running into a stationary ship
anthropogenic	Generated by human activity
archaeological resource	Historical place, site, building, shipwreck, or other archaeological site on the landscape
below grade	Below ground level
benthic	Related to the bottom of a body of water
benthic resources	The seafloor surface, the substrate itself, and the communities of bottom-dwelling organisms that live within these habitats
Cetacea	Order of aquatic mammals made up of whales, dolphins, porpoises, and related lifeforms
coastal habitat	Coastal areas where flora and fauna live, including salt marshes and aquatic habitats
coastal waters	Waters in nearshore areas where bottom depth is less than 98.4 feet (30 meters)
coastal zone	The lands and waters starting at 3 nautical mile (nm) from the land and ending at the first major land transportation route
commercial fisheries	Areas or entities raising and catching fish for commercial profit
commercial-scale wind energy facility	Wind energy facility usually greater than 1 megawatt (MW) that sells the produced electricity
criteria pollutant	One of six common air pollutants for which the United States Environmental Protection Agency sets National Ambient Air Quality Standards: carbon monoxide, lead, nitrogen dioxide, ozone, particulate matter, or sulfur dioxide
critical habitat	Geographic area containing features essential to the conservation of threated or endangered species
cultural resource	Historical districts, objects, places, sites, buildings, shipwrecks, and archaeological sites on the American landscape, as well as sites of traditional, religious, or cultural significance to cultural groups, including Native American tribes
culvert	structure, usually a tunnel, allowing water to flow under an obstruction (e.g., road, trail)
demersal	Living close to the ocean floor
design envelope	The range of proposed project characteristics defined by the applicant and used by Bureau of Ocean Energy Management (BOEM) for purposes of environmental review and permitting
dredging	Removal of sediments and debris from the bottom of lakes, rivers, harbors, and other waterbodies
duct bank	Underground structure that houses the onshore export cables, which consists of polyvinyl chloride pipes encased in concrete

Term	Definition
ecosystem	Community of interacting living organisms and nonliving components (such as air, water, soil)
electromagnetic field	A field of force produced by electrically charged objects and containing both electric and magnetic components
embayment	Recessed part of a shoreline
endangered species	A species that is in danger of extinction in all or a significant portion of its range
Endangered Species Act–listed species	Species listed under the Endangered Species Act (ESA) of 1973 (as amended)
environmental protection measure	Measure proposed to avoid or minimize potential impacts
ensonification	The process of filling with sound
environmental consequences	The potential direct, indirect, and cumulative impacts that the construction, operations and maintenance (O&M), and decommissioning of a proposed project would have on the environment
environmental justice communities	Minority and low-income populations affected by a proposed project
epifauna	Fauna that lives on the surface of a seabed (or riverbed), or is attached to underwater objects or aquatic plants or animals
essential fish habitat	Those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity (50 code of federal regulations [CFR] 600)
export cables	Cables connecting the wind facility to the onshore electrical grid power
export cable corridor	Area identified for routing the entire length of the onshore and offshore export cables
federal aids to navigation	Visual references operated and maintained by the United States Coast Guard (USCG), including radar transponders, lights, sound signals, buoys, and lighthouses, that support safe maritime navigation
finfish	Vertebrate and cartilaginous fishery species, not including crustaceans, cephalopods, or other mollusks
for-hire commercial fishing	Commercial fishing on a for-hire vessel (i.e., a vessel on which the passengers make a contribution to a person having an interest in the vessel in exchange for carriage)
for-hire recreational fishing	Fishing from a vessel carrying a passenger for hire who is engaged in recreational fishing
foundation	The bases to which the wind turbine generators (WTGs) and offshore substation platforms (OSPs) are installed on the seabed; four types of foundations have been considered and reviewed for the Project: monopile, piled jacket, suction bucket, and gravity based
geomagnetic	Relating to the magnetism of the Earth
gravity-based structure	Typically constructed of steel, concrete, or a combination of both, gravity-based structures sit on top of the sea floor and are not pile driven
hard-bottom habitat	Benthic habitats composed of hard-bottom (e.g., cobble, rock, and ledge) substrates

Term	Definition
historic property	Prehistoric or historic district, site, building, structure, or object that is eligible for or already listed in the National Register of Historic Places (NRHP); also includes any artifacts, records, and remains (surface or subsurface) related to and located within such a resource
historical resource	Prehistoric or historic district, site, building, structure, or object that is eligible for or already listed in the NRHP; also includes any artifacts, records, and remains (surface or subsurface) related to and located within such a resource
horizontal directional drilling	Trenchless technique for installing underground cables, pipes, and conduits using a surface-launched drilling rig
hull	Watertight frame or body of a ship
infauna	Fauna living in the sediments of the ocean floor (or river or lake beds)
interarray cables	Cables connecting the wind turbine generators to the electrical service platforms
invertebrate	Animal with no backbone
jacket foundation	Latticed steel frame with three or four supporting piles driven into the seabed
jack-up vessel	Mobile and self-elevating platform with buoyant hull
jet excavation	Process of moving or removing soil with a jet
jet plowing	Plowing in which the jet plow, with an adjustable blade, or plow, rests on the seafloor and is towed by a surface vessel; the jet plow creates a narrow trench at the designated depth, while water jets fluidize the sediment within the trench; in the case of the proposed Project, the cables would then be fed through the plow and laid into the trench as it moves forward; the fluidized sediments then settle back down into the trench and bury the cable
knot	Unit of speed equaling 1 nm (1.8 kilometer) per hour
landfall site	The shoreline landing site at which the offshore cable transitions to onshore
marine mammal	Aquatic vertebrate distinguished by the presence of mammary glands, hair, three middle ear bones, and a neocortex (a region of the brain)
marine waters	Waters in offshore areas where bottom depth is more than 98.4 feet (30 meters)
mechanical cutter	Method of submarine cable installation equipment that involves a cutting wheel or excavation chain to cut a narrow trench into the seabed allowing the cable to sink under its own weight or be pushed to the bottom of the trench via a cable depressor
mechanical plow	Method of submarine cable installation equipment that involves pulling a plow along the cable route to lay and bury the cable; the plow's share cuts into the soil, opening a temporary trench, which is held open by the side walls of the share, while the cable is lowered to the base of the trench via a depressor; some plows may use additional jets to fluidize the soil in front of the share
monopile or monopile foundation	A long steel tube driven into the seabed that supports a tower
nautical mile	A unit used to measure sea distances and equivalent to approximately 1.15 miles (1.85 kilometers)
offshore substation	The interconnection point between the WTGs and the export cable; the necessary electrical equipment needed to connect the inter-array cables to the offshore export cables
onshore substation	Substation connecting the proposed Project to the existing bulk power grid system

Term	Definition
operations and maintenance facilities	Would include offices, control rooms, warehouses, shop space, and pier space
Outer Continental Shelf	All submerged land, subsoil, and seabed belonging to the United States but outside of states' jurisdiction
pile	A type a foundation akin to a pole
pile driving	Installing foundation piles by driving them into the seafloor
pinnipeds	Carnivorous, semiaquatic marine mammals with fins, also known as seals
pin pile	Small-diameter pipe driven into the ground as foundation support
plume	Column of fluid moving through another fluid
private aids to navigation	Visual references on structures positioned in or near navigable waters of the U.S., including radar transponders, lights, sound signals, buoys, and lighthouses, that support safe maritime navigation; permits for the aids are administered by USCG
Project area	The combined onshore and offshore area where proposed Project components would be located
protected species	Endangered or threatened species that receive federal protection under the ESA of 1973 (as amended)
scour protection	Protection consisting of rock and stone that would be placed around all foundations to stabilize the seabed near the foundations as well as the foundations themselves
scrublands	Plant community dominated by shrubs and often also including grasses and herbs
sessile	Attached directly by the base
silt substrate	Substrate made of a granular material originating from quartz and feldspar, and whose size is between sand and clay
soft-bottom habitat	Benthic habitats include soft-bottom (i.e., unconsolidated sediments) and hard-bottom (e.g., cobble, rock, ledge) substrates, as well as biogenic habitat (e.g., eelgrass, mussel beds, worm tubes) created by structure-forming species
substrate	Earthy material at the bottom of a marine habitat; the natural environment that an organism lives in
suction-bucket jacket	Latticed steel frame with three to four supporting suction-bucket foundations securing the structure to the seabed
suspended sediments	Very fine soil particles that remain in suspension in water for a considerable period of time without contact with the bottom; such material remains in suspension due to the upward components of turbulence and currents, or by suspension
threatened species	A species that is likely to become endangered within the foreseeable future
tidal energy project	Project related to the conversion of the energy of tides into usable energy, usually electricity
tidal flushing	Replacement of water in an estuary or bay because of tidal flow
trawl	A large fishing net dragged by a vessel at the bottom or in the middle of sea or lake water
turbidity	A measure of water clarity
utility right-of-way	Registered easement on private land that allows utility companies to access the utilities or services located there

Term	Definition
vibracore	Technology/technique for collecting core samples of underwater sediments and wetland soils
viewshed	Area visible from a specific location
visual resource	The visible physical features on a landscape, including natural elements such as topography, landforms, water, vegetation, and anthropogenic structures
wetland	Land saturated with water; marshes; swamps
wind energy	Electricity from naturally occurring wind
wind energy area	Areas with significant wind energy potential and defined by BOEM
wind turbine generator	Component that puts out electricity in a structure that converts kinetic energy from wind into electricity

Appendix L: List of Preparers and Reviewers

L.1 List of Preparer and Reviews

Table L-1. Bureau of Ocean Energy Management contributors

Name	Role/Resource Area
National Environmental Policy Act (NEPA) Coordinator	
Brune, Genevieve	Environmental Protection Specialist
Resource Scientists and Contributors	
Ajilore, Ololade	Navigation and Vessel Traffic
Baker, Arianna	Navigation and Vessel Traffic
Baker, Kyle	Marine Mammals; Sea Turtles
Beser, Todd (USACE)	Wetlands
Bigger, David	Birds; Bats; Coastal Habitat and Fauna
Browning, Jeffrey	Project Coordinator
Brune, Genevieve	Land Use and Coastal Infrastructure
Bucatari, Jennifer	Other Uses (Marine Minerals)
Chaiken, Emma	Commercial Fisheries and For Hire Recreational Fishing
Chakey, Sindey	Environmental Justice; Recreation and Tourism; CZMA
Conrad, Alex	Finfish, Invertebrates, and Essential Fish Habitat; Marine Mammals; Sea Turtles
Cornelison, Meghan	Environmental Justice
Draher, Jennifer	Water Quality
Fulling, Gregory	Marine Mammals; Sea Turtles
Horrell, Christopher	Cultural Resources
Jensen, Brandon	Benthic Resources; Coastal Habitat and Fauna; Finfish, Invertebrates, and Essential Fish Habitat; Wetlands; Commercial Fisheries and For-Hire Recreational Fishing; Other Uses (Scientific Research and Surveys)
Jensen, Mark	Commercial Fisheries and For-Hire Recreational Fishing; Demographics, Employment, and Economics; Recreation and Tourism
Lewis, Jo'Anne	Navigation and Vessel Traffic; Other Uses (SAR)
McCarty, John	Scenic and Visual Resources; Recreation and Tourism
McCoy, Angel	Meteorologist
McGuffin, Andrew	Other Uses (Cables and Pipelines)
Miller, Jennifer	Other Uses (Radar Systems)
Moshier, Marissa	Cultural Resources and Section 106 Lead

Name	Role/Resource Area
O’Connell, Daniel	Technical Design Elements
Oliver, Elizabeth	Tribal Liaison
Pollock, Jayson	Commercial Fisheries and For Hire Recreational Fishing
Richards, Renee	Other Uses (Cables and Pipelines; Radar Systems)
Schnitzer, Laura	Cultural Resources
Slayton, Ian	Air Quality; Cumulative
Stokely, Sarah	Cultural Resources
Sullivan, Kimberly	Environmental Justice
Wisman, Jeri	Marine Mammals; Sea Turtles
Wolf, Jacob	Air Quality

Table L-2. Reviewers

Name	Title	Agency
Bureau of Ocean Energy Management (BOEM) and U.S. Department of the Interior (DOI) Reviewers		
Brown, William Y.	Chief Environmental Officer	BOEM
Hildreth, Emily	Renewable Energy Policy Specialist	BOEM
Krevor, Brian	Lead Environmental Protection Specialist	BOEM
Landers, Lisa	BOEM NEPA Section Chief	BOEM
Melendez-Arreaga, Pedro	Lead Attorney-Advisor, Office of the Solicitor	DOI
Morin, Michelle	Chief, Environmental Branch for Renewable Energy	BOEM
Ottman, Noel	Attorney-Advisor, Office of the Solicitor	DOI
Sebastian, Robert	Lead Attorney-Advisor, Office of the Solicitor	DOI
Stromberg, Jessica	Deputy Chief, Environmental Branch for Renewable Energy	DOI
Vorkoper, Stephen	Attorney-Advisor, Office of the Solicitor	DOI
Cooperating and Participating Agency Reviewers		
Boeri, Robert	Project Review Coordinator/Dredging Coordinator	Massachusetts Office of Coastal Zone Management
Brien, Ruthann	Regulatory Project Manager	U.S. Army Corps of Engineers (USACE)
Butler, Ryan	Lieutenant Commander	U.S. Coast Guard (USCG)
DeMeo, Sharon	Region 1 Staff	Environmental Protection Agency (USEPA)
Desautels, Michele	District 1 Staff	USCG
Gaito, Danielle	Region 1 Staff	USEPA

Name	Title	Agency
Haight, Terra	Ocean and Lakes Policy Analyst	New York State Department of State
Heckman, Andrea	Lead Environmental Protection Specialist	Bureau of Safety and Environmental Enforcement (BSEE)
Krueger, Mary	Energy Specialist, Interior Region 1, North Atlantic-Appalachian	National Park Service
McLean, Laura	Ocean and Lakes Policy Analyst	New York State Department of State
Pentony, Michael	Regional Administrator	National Marine Fisheries Service
Sinclair, Jim	Marine Ecologist	BSEE
Sparkman, Christopher	Marine Information Specialist	USCG
Teixeira, Stacy	Coast Guard Officer/Emergency Management	USCG
Timmermann, Timothy	Director, Office of Environmental Review, New England-Region 1	USEPA
Tuttle, Graham	Marine Protected Species Program National Lead	BSEE
West, Stephen	Commander	USCG

Table L-3. Consultants

Name	Company	Role/Resource Area
Ackerman, Caitlyn	ICF	Environmental Justice; Demographics, Employment, and Economics
Baer, Sarah	ICF	Land Use and Coastal Infrastructure; Demographics, Employment, and Economics
Bartlett, Alex	ICF	Wetlands
Coleman, Randall	ICF (formerly)	Project Manager
Crawford, Karen	ICF	Cultural Resources and Section 106 Lead
Diller, Elizabeth	ICF	Project Director
Ernst, David	ICF	Air Quality
Gleaton, Soniya	ICF	Comment Processing
Ha, Anthony	ICF	Publications Specialist
Hatfield, Teresa	ICF	Navigation and Vessel Traffic
Jost, Rebecca	ICF	Other Uses, Recreation and Tourism
Lanza, Robert	ICF	Planned Activities Scenario
Lundstrom, Kristen	ICF	Editor
McCoy, Maureen	ICF	Cultural Resources and Section 106 Support
Muntz, Alice	ICF	Cultural Resources and Section 106 Support
ODonnell, Megan	ICF	Project Manager

Name	Company	Role/Resource Area
Paulson, Merlyn	ICF (formerly)	Scenic and Visual Resources
Schanel, Pam	ICF	Public Involvement
Slankard, Scott	ICF	Water Quality
Thoene, Jason	ICF	Geographic Information Systems
Weaver, Alexis	ICF	Project Coordinator
Conetta, Dennis	RPS	Benthic Resources, Marine Mammals
Dauksis, Russell	RPS	Benthic Resources, Commercial Fisheries and For-Hire Recreational Fishing, Sea Turtles, Coastal Habitats and Fauna
Davies, Stephen	RPS	Commercial Fisheries and For-Hire Recreational Fishing, Finfish and Invertebrates
Garvey, Derek	RPS	Finfish and Invertebrates, Sea Turtles, Marine Mammals
Morandi, Alicia	RPS (formerly)	Project Manager, Reviewer, Sea Turtles, Marine Mammals, Coastal Habitats and Fauna
Misa, Paula	RPS	Project Manager, Reviewer, Sea Turtles, Marine Mammals, Finfish and Invertebrates
Misa, William	RPS	Benthic Resources, Finfish and Invertebrates, Marine Mammals

Appendix M: Distribution List

This Environmental Impact Statement (EIS) is available in electronic form for public viewing at https://www.boem.gov/southcoast-wind. Hard copies and digital copies of the EIS can be requested by contacting the Program Manager, Office of Renewable Energy in Sterling, Virginia. Publication of the draft EIS initiated a 60-day comment period where government agencies, members of the public, and interested stakeholders could provide comments and input. The Bureau of Ocean Energy Management (BOEM) accepted comments received or postmarked no later than April 18, 2023, in any of the following ways:

- In hard copy form, delivered by hand or by mail, enclosed in an envelope labeled "Mayflower Wind COP EIS" and addressed to Program Manager, Office of Renewable Energy, Bureau of Ocean Energy Management, 45600 Woodland Road, Sterling, Virginia 20166.
- Through the regulations.gov web portal by navigating to http://www.regulations.gov and searching for docket number "BOEM-2023-0011."
- By attending one of the EIS public meetings on the dates listed in the notice of availability and providing written or verbal comments.

BOEM used comments received during the public comment period to inform its preparation of the Final EIS, as appropriate. EIS notification lists for the Project are provided in Table M-1 through Table M-5.

M.1 Notification List

Table M-1. Federal agencies

Agency	Contact
Cooperating Federal Agencies	
U.S. Army Corps of Engineers (USACE)	Naomi Handell, Regulatory Program Manager, USACE North Atlantic Division Roberta Budnik, Regulatory Division, New England District
Bureau of Safety and Environmental Enforcement	Jordan Creed, FAST-41 Coordinator Andrea Heckman, Office of Environmental Compliance
Environmental Protection Agency	Timothy Timmerman, National Environmental Policy Act Program Manager, Region 1
National Marine Fisheries Service	Sue Tuxbury, Fishery Biologist/Wind Coordinator, Greater Atlantic Regional Fisheries Office, Habitat and Ecosystems Services Division
United States Coast Guard	Michele Desautels, District 1
Participating Federal Agencies	
Fish and Wildlife Service	Audrey Mayer, Field Supervisor, New England Field Office Jane Ledwin, Infrastructure Streamlining Coordinator
National Park Service	Mary Krueger, Energy Specialist, Project Lead
Department of Navy	Matt Senska, Director, Marine Resources and At-Sea Policy

Agency	Contact
Department of Defense	Steven Sample, Executive Director, Department of Defense Siting Clearinghouse
Advisory Council on Historic Preservation	Blythe Semmer, Assistant Director for Special Initiatives

Table M-2. State agencies

Agency	Contact
Cooperating State Agencies	
Massachusetts Office of Coastal Zone Management	Lisa Engler, Director
Rhode Island Coastal Resources Management Council	Jeffrey Willis, Executive Director
State of New York Department of State	Michael Snyder, Ocean and Great Lakes Program Manager Terra Haight, Ocean and Lakes Policy Analyst

Table M-3. Federally Recognized Tribal Nations and Native organizations

Tribal Nation	Contact
Delaware Tribe of Indians	Susan Bachor, Archaeologist, Deputy Tribal Historic Preservation Officer Representative Brad KillsCrow, Chief Joanna Maurer, GIS Specialist Martina Thomas, Preservation Generalist Tristen Tucker, Environmental Program Director
Mashantucket (Western) Pequot Tribal Nation	Rodney Butler, Chairman Stormy Hay, THPO Coordinator Michael Kickingbear Johnson, Acting Tribal Historic Preservation Officer Crystal Whipple, Vice Chairwoman Joelina G. Whitford-Anthony, THPO Coordinator
Mashpee Wampanoag Tribe	Carlton Hendricks, Vice Chairman Jason Steiding, Natural Resources Department Brian Weeden, Chairman David Weeden, THPO
Mohegan Tribe of Indians of Connecticut	James Gessner, Chairman Jean McInnis, Environmental Protection Administrator James Quinn, Tribal Historic Preservation Officer
The Narragansett Indian Tribe	John Brown, Tribal Historic Preservation Officer Anthony Dean Stanton, Sachem Dinalyn Spears, Natural Resource Manager
The Shinnecock Indian Nation	T. Rainbow Chavis Jason Cofield, Director of Tribal Operations Rachel Valdez-Castillo, THPO

Tribal Nation	Contact
Wampanoag Tribe of Gay Head (Aquinnah)	Cheryl Andrews-Maltais, Chairwoman Kevin Devine, Councilman Lael Echo-Hawk, General Counsel Kimberlina Gomez Ryan Sawyer Barbara Spain, Executive Assistant Jennifer Wade, Consultant for Tribe Bettina Washington, Tribal Historic Preservation Officer

List of Tables

N.1 Introduction

On February 17, 2023, the Bureau of Ocean Energy Management (BOEM) published a notice of availability for the SouthCoast Wind Project (Project) Draft Environmental Impact Statement (EIS), consistent with the regulations implementing the National Environmental Policy Act (NEPA; 42 U.S. Code [USC] 4321 et seq.), to assess the potential impacts of the Proposed Action and alternatives. The Draft EIS was made available in electronic form for public viewing at https://www.boem.gov/renewable-energy/state-activities/southcoast-wind, and hard copies or electronic copies were delivered to other entities as specified in Appendix M of the Draft EIS. The NEPA review process requires agencies to allow the public the opportunity to comment on a Draft EIS. The notice of availability initiated a 45-day public comment period for the Draft EIS. BOEM extended the public comment period by 15 days. The comment period closed on April 18, 2023. This appendix describes the Draft EIS public comment processing methodology and definitions, includes responses to comments received on the Draft EIS, and describes where specific updates to the Final EIS can be found in the document.

N.2 Objective

BOEM reviewed and considered all written and oral public submissions received during the Draft EIS public review and comment period. BOEM's goal was to identify comments to be addressed in this Final EIS and to categorize those comments based on the applicable resource areas or NEPA topics. This categorization scheme allowed subject matter experts to review comments directly related to their areas of expertise and allowed BOEM to generate statistics based on the resource areas or NEPA topics addressed in each of the comments. All public comment submissions received can be viewed online at http://www.regulations.gov by typing "BOEM-2023-0011" in the search field.

N.3 Methodology

N.3.1 Terminology

The following terminology is used throughout this appendix:

- Submission: The entire content submitted by a single person or group at a single time. For example, a 10-page letter from a citizen, an email with a portable document format (PDF) attachment, and a transcript of an oral comment given at a public hearing meeting were each considered to be a submission.
- Comment: A specific statement within a submission that expresses a sender's specific point of view, concern, question, or suggestion. A comment can consist of more than once sentence, as long as those grouped sentences express a single idea. One submission may contain many comments.
- Substantive Comment: Draft EIS submissions were reviewed to identify and categorize "substantive" comments. To be substantive, a comment must relate to the reasonably foreseeable impacts of the Proposed Action, alternatives, or cumulative actions and do one or more of the following:

- Question (with supporting rationale) the accuracy of information in the Draft EIS
- Question (with supporting rationale) the adequacy of, methodology for, or assumptions used for the environmental analysis
- Present new information relevant to the analysis
- Present reasonable alternatives or mitigation measures other than those analyzed in the Draft EIS
- Present or cause modifications to alternatives or mitigation measures analyzed in the Draft EIS
- Correct factual errors in the content of the Draft EIS

- General Comment: General comments are comments other than substantive comments. General comments may: (1) express interest or concern regarding an impact topic without providing specific comments on the information, methods, or findings presented in the Draft EIS, (2) express general support for or opposition to the proposed Project, or (3) comment on a topic unrelated to the proposed Project.

N.3.2 Comment Submittals

Federal agencies, tribal governments, state/local governments, and the general public had the opportunity to provide comments on the Draft EIS via the following mechanisms.

- Electronic submissions via www.regulations.gov on docket number BOEM-2023-0011.
- Hard-copy comment letters submitted to BOEM via traditional mail.
- Comments submitted verbally at each of the public hearings.

BOEM held three online public hearings via Zoom to solicit verbal comments to inform preparation of the Final EIS. The hearings were free and open to the public with no reservations required. Locations and dates of these hearings are outlined in Table N.3-1.

Table N.3-1. Public hearings

Date	Time	Location
March 20, 2023	5:00 p.m. Eastern Time	Zoom Webinar: https://www.boem.gov/renewable-energy/state-activities/boem-southcoast-public-meeting-3202023
March 22, 2023	1:00 p.m. Eastern Time	Zoom Webinar: https://www.boem.gov/renewable-energy/state-activities/boem-southcoast-public-meeting-3222023
March 27, 2023	5:00 p.m. Eastern Time	Zoom Webinar: https://www.boem.gov/renewable-energy/state-activities/boem-southcoast-public-meeting-3272023

All submissions initially provided by methods other than www.regulations.gov, including the transcripts of comments recorded at each public hearing listed in Table N.3-1, were uploaded to the docket. Each submission, including testimony by individual speakers at the public hearings listed in Table N.3-1, was assigned a unique identification number. That unique Submission ID was retained throughout the comment management process, for both submissions and the individual comments within those submissions.

N.3.3 Comment Processing

BOEM downloaded and reviewed all submissions from regulations.gov. These submissions were provided in Hypertext Markup Language (html) format, while attachments provided by stakeholders as part of their regulations.gov submission were typically provided in PDF or Microsoft Word format. Text from all formats was parsed, coded, and exported into a single Microsoft Excel file that served as the primary submission database. In cases where an attachment did not contain comments specific to the docket for the SouthCoast Wind Draft EIS, the attachment was retained separately for BOEM reference as applicable, linked to the main body of the submission through the unique Submission ID. Examples of this type of attachment include copies of comment letters that were originally submitted during the scoping period, copies of comment letters that were originally submitted on another docket, or attached photos, published reports, news articles, or other secondary material. The submission database also included information about each submission, including the submitter's contact information, submission date, and whether the submitter was a government entity or agency.

Each submission and all oral testimonies were read to identify individual substantive and general comments (as defined under N.3.1, *Terminology*). Each comment was parsed, coded, and exported to a spreadsheet that served as the master comment database. Each comment then received a unique comment ID number, tied to the Submission ID. For example, the fourth comment identified in regulations.gov submission 0005 was identified as BOEM-2023-0011-0005-0004.

Substantive comments from cooperating agencies were organized by agency and are presented verbatim in N.4. Other agency, stakeholder, and public comments were each assigned to one section of the Draft EIS, based on the document's table of contents, or to a general topic such as "NEPA/Public Involvement Process." Substantive comments are presented verbatim in Section N.5. General comments are summarized in Section N.7 and the specific comments that contributed to a comment summary are identified by comment number.

N.4 Responses to Cooperating and Participating Agency Comments on the Draft EIS

N.4.1 Cooperating Federal Agencies

N.4.1.1 National Oceanic and Atmospheric Administration, National Marine Fisheries Service

Table N.4.1-1. Responses to comments from National Ocean and Atmospheric Administration, National Marine Fisheries Service (BOEM-2023-0011-0185)

Comment No.	Comment	Response
BOEM-2023-0011-0185-0001	One of our most significant concerns involves the potential impacts of the construction and operation of this project on endangered North Atlantic right whales. As described in previous correspondence Nantucket Shoals and adjacent waters are a biologically important area for right whales and a primary winter foraging aggregation area for right whales (see for example Quintana-Rizzo et al. 2021 Davis et al. 2017). Use of this area has increased significantly since 2010 as right whale habitat use has shifted (Quintana-Rizzo et al. 2021 NMFS 2022). Without the implementation of robust and effective mitigation measures it is our view that significant impacts on North Atlantic right whales may occur from project construction and operation due to direct impacts on North Atlantic right whales during construction long-term impacts to foraging as a result of project operations and potential mortality or serious injury from vessel strikes over the life of the project. The DEIS preliminarily concludes that the proposed mitigation measures are not sufficient to avoid vessel strike on North Atlantic right whales. BOEM concludes in the DEIS that vessel strike of a North Atlantic right whale cannot be ruled out even with SouthCoast Wind's proposed avoidance minimization and mitigation measures (AMMs). The death of a single North Atlantic right whale would have population level consequences; therefore impacts of vessel traffic are considered major in the DEIS. As such BOEM	The EIS addresses the known use of the Project area, including the vicinity to marine mammal habitat and proximity to Nantucket Shoals, and considers the importance of these habitats. Final Environmental Impact Statement (EIS) Section 3.5.6, *Marin Mammals,* discusses the potential impact of the proposed Project on marine mammals and has been revised to include more detail on the Project's proposed mitigation measures that specifically focus on protecting North Atlantic right whales (NARWs). In response to concerns related to pile-driving activities occurring in the Nantucket Shoals region, SouthCoast Wind proposed a NARW Mitigation and Monitoring Plan (Appendix G, Attachment G-3) This plan intends to supplement the existing applicant-proposed monitoring mitigation measures and includes expanded monitoring coverage of the pre-start clearance and shutdown zones and Level B harassment zones within the National Marine Fisheries Service (NMFS) area of concern (20 kilometers [km] of the 30-meter isobath on the west side of Nantucket Shoals). Measures in this plan also include SouthCoast Wind's commitment to only use impact pile driving during the installation of the foundations associated with Project 1 in the northern portion of the Lease Area (Project 1), which includes all locations within the NMFS area of concern.

Comment No.	Comment	Response
	should require additional mitigation measures that would minimize risk of vessel strike such that it would not be expected to occur; any such measures should be clearly described and their impact and effectiveness analyzed in the FEIS.	A comprehensive list of mitigation and monitoring measures (Appendix G, Table G-1, under *Vessel Operations*) that would be implemented to avoid, minimize, and mitigate adverse impacts on marine mammals, specifically the NARW. These measures include, but are not limited to, avoidance of peak NARW seasonal presence, use of sound attenuation technologies, use of Protected Species Observers (PSOs), passive acoustic monitoring (PAM), soft-start procedures, shutdown procedures, and other measures. These mitigation measures will effectively eliminate the risk of vessel strikes, and the EIS has been updated to state this more clearly. The Bureau of Ocean Energy Management (BOEM) and NMFS continue to work together to use the best available information to determine appropriate mitigation measures. Additionally, mitigation and monitoring measures may arise from consultations from federal and state resource agencies and will be considered by decision-makers and potentially adopted as conditions for approval as necessary.
BOEM-2023-0011-0185-0002	We have previously expressed concern about the operational impacts of the project on North Atlantic right whales. Those concerns remain. We continue to encourage BOEM to more fully evaluate the available literature to assess the impacts of the presence of structures and operation of WTGs on ecological conditions that support right whale foraging in Southern New England and to develop measures to avoid and minimize these effects from the SouthCoast Wind project. While we agree that there is some uncertainty and more research is needed the DEIS does not fully evaluate the extent of all potential impacts in the Presence of Structures section for the proposed action (Alternative B section 3.5.6.5). The DEIS does not recognize the importance of Nantucket Shoals and surrounding waters as a primary foraging habitat for North Atlantic right whales and does not fully address the potential effects of the action including the approximately 30-year operational period on North Atlantic right whale prey foraging behavior and health and fitness of	BOEM has partnered with the National Academies of Science Engineering and Math (NASEM) for an independent peer review of potential hydrodynamic impacts for offshore wind facilities on prey species. The report concluded that hydrodynamic impacts from offshore wind projects adjacent to Nantucket Shoals will likely be difficult to distinguish from the ongoing effects of climate change currently occurring in this region. Likewise, BOEM finds that measurable impacts of offshore wind farms to the foraging success of whales that would result in population-level effects are not reasonably likely to occur and that a recommended NARW conservation buffer is not warranted based on the review of best available information and expert opinion found in the report. Further monitoring studies would be needed to have the spatial and temporal coverage to adequately understand the impact of future wind farms, and BOEM will continue to coordinate with partners to develop regional monitoring strategies to obtain scientific information on the potential hydrodynamic

Comment No.	Comment	Response
	individual right whales. As currently written the impact determination for Presence of Structures focuses on reef effects and accumulation of ghost gear. It does not provide any conclusion related to oceanographic or wind wake effects on the abundance or distribution of prey or the effects on North Atlantic right whale foraging within the SouthCoast Wind project area or the surrounding waters of Nantucket Shoals. We consider these issues and effects to be significant requiring focused attention and evaluation in the FEIS.	effects of wind turbine generators (WTGs). Based on the current information available, including the initial meetings associated with the peer review, BOEM is of the position that the current National Environmental Policy Act (NEPA) and Endangered Species Act (ESA) analyses accurately reflect the expected impacts on NARWs from offshore wind projects, as well as provide an adequate suite of measures to avoid, minimize, or mitigate impacts on NARWs.
BOEM-2023-0011-0185-0003	BOEM has included Alternative D which considers the removal of up to six turbine locations at the northern end of the lease as an alternative to reduce impacts to North Atlantic right whales. However as acknowledged in the DEIS this alternative would have no appreciable reduction in impacts on North Atlantic right whales as compared to the proposed action (which the DEIS describes as a major impact). We agree with BOEM's determination that Alternative D would provide no meaningful difference for North Atlantic right whales from the proposed action and recommend that BOEM not carry this alternative forward for full evaluation (i.e. include in the FEIS as considered but not carried forward). NMFS provided a recommended alternative that would have precluded development of WTGs within a 20-km buffer of the Nantucket Shoals 30- meter isobath which was not carried forward by BOEM based on the determination that it was not economically feasible. NMFS recommends that BOEM works with NMFS to identify and	The primary basis for the recommended alternative, as presented by NMFS, is the potential for the presence of WTGs to result in hydrodynamic effects that change zooplankton productivity and aggregations, which may reduce foraging opportunities for the NARW. Based on best available science, BOEM believes there is a lack of conclusive evidence that the proposed WTG locations within the Lease Area have the potential to result in hydrodynamic effects on NARW foraging in the vicinity of Nantucket Shoals.[1] The best available science suggests that effects are most likely to be localized to the immediate vicinity of the turbine array and to not extend to Nantucket Shoals. Primary studies supporting this position include modeling of the full build-out of the southern New England lease areas (Johnson et al. 2021), hydrodynamic studies of wind facilities in the North Sea (Christiansen et al. 2022), and recent comprehensive literature reviews (NASEM 2024). In particular, the NASEM study was commissioned to "evaluate the potential for

[1] Two of the primary conclusions from the NASEM report *Potential Hydrodynamic Impacts of Offshore Wind Energy on Nantucket Shoals Regional Ecology: An Evaluation from Wind to Whales* (2024) demonstrate that it is not reasonable to conclude eliminating a large number of WTGs from SouthCoast Wind would have a significant beneficial effect. Specifically, "**Conclusion:** The paucity of observations and uncertainty of the modeled hydrodynamic effects of wind energy development at the turbine, wind farm, and regional scales make potential ecological impacts of turbines difficult to predict and/or detect." and "**Conclusion:** The hydrodynamic impacts from offshore wind development in the Nantucket Shoals region on zooplankton will be difficult to isolate from the much larger magnitude of variability introduced by natural and other anthropogenic sources (including climate change) in this dynamic and evolving oceanographic and ecological system."

Comment No.	Comment	Response
	analyze an alternative that would meaningfully reduce impacts of the project including considering the removal of a greater number of turbine positions in the northern portion of the lease area. We also request that you revisit the “Preclude the Development of WTGs within a 20-kilometer buffer of the Nantucket Shoals 30-meter isobath” and the “Eliminate up to 17 WTGs in the northeastern portion of the Lease Area” alternatives.	offshore wind farms in the Nantucket Shoals region to affect oceanic physical processes, and, in turn, how those hydrodynamic alterations might affect local regional ecosystems.” The study, titled *Potential Hydrodynamic Impacts of Offshore Wind Energy on Nantucket Shoals Regional Ecology: An Evaluation from Wind to Whales,* concluded that “the impacts of offshore wind projects on the NARW and the availability of their prey in the Nantucket Shoals will likely be difficult to distinguish from the significant impacts of climate change and other influences on the ecosystem” (NASEM 2023). Furthermore, the key recommendation from the study is “while wind energy planning and development progresses, the BOEM, NOAA, and others should promote observational studies and modeling that will advance understanding of potential hydrodynamic effects and their consequent impacts on ecology in the Nantucket Shoals region during all phases of wind energy development.” BOEM is also supporting additional research on this topic, in accordance with the NASEM recommendations. During the process of identifying the Massachusetts lease areas BOEM excluded certain areas identified as important habitats that could be affected if ultimately developed with the installation of WTGs. Nantucket Shoals was among the areas excluded from the subsequent commercial leasing. BOEM does not assert there are no effects from wind turbine wake and corresponding wind speed and clarifies that the effects would not likely have a detectable effect on foraging and would not have population-level impacts on important species including NARW. Without impacts on foraging and a reasonable causal connection to population impacts, NMFS’s reasoning for this alternative is not justifiable or persuasive. NMFS has not demonstrated its 20-kilometer buffer alternative is warranted or provided any new information to support it, and current available peer-reviewed studies and data constituting best available science do not conclude that

Comment No.	Comment	Response
		there would be a reasonable expectation of population-level impacts.
BOEM-2023-0011-0185-0004	In order to issue an Incidental Take Authorization (ITA) under the MMPA NMFS OPR needs to make a determination that the authorized take will have a "negligible impact" on the stock. Many studies spanning marine mammal taxa and sound source types show noise exposure may result in behavioral disruption including avoidance and foraging cessation (see for example Southall et al. 2021 Duarte et al. 2021 Goldbogen et al. 2013). Persistent disturbance of foraging can accrue to impact reproduction and survival especially for unhealthy animals with limited energy reserves (Keen et al. 2021 McHuron et al. 2021 Pirotta et al. 2023). For populations with low abundance high mortality rates and low reproductive rates impacts to reproductive success or survival of any individuals can adversely impact populations. As you are aware NMFS OPR has proposed pile driving-related mitigation measures for SouthCoast to mitigate the impacts from construction related noise adequately for NMFS to be able to make a negligible impact determination. Also we continue to work with SouthCoast to identify and include measures that would adequately reduce the risk of vessel strike such that zero strikes are expected which is also necessary in order to make negligible impact determination.	BOEM has proposed a suite of mitigation, monitoring, and reporting conditions that are expected to avoid and minimize any potential impacts. These measures include seasonal restrictions on pile driving to times of year during which NARWs are least likely to occur. Additionally, conditions are proposed to lower sound levels that would decrease the area in which whales might be exposed. The monitoring conditions would also avoid exposure to noise when whales are sighted by not allowing pile driving to occur or by minimizing the duration of exposure such that long-term reductions in foraging would not occur. Stringent vessel strike avoidance measures are also proposed that go above and beyond what NMFS requires through regulation. BOEM agrees with NMFS regarding the status of the NARW, including the overall concerns for the recovery of the population. BOEM will continue to work cooperatively with NMFS to assess the best available information and identify any conditions that are reasonable provided support and analysis based upon such information.
BOEM-2023-0011-0185-0005	Last we remain concerned about the impacts of installing and operating wind turbines in North Atlantic right whale feeding habitat and how that will impact right whale foraging success. As we have clearly articulated to SouthCoast additional habitat mitigation may be necessary prior to the issuance of any final rule and will be informed by the ESA section 7 consultation and public comments on the proposed rule. NMFS OPR will continue to work with you on these issues and in particular discuss both how the NEPA process may be affected and how the additional mitigation measures can be incorporated into and analyzed in the FEIS.	Thank you for the comment. BOEM remains committed to avoiding and minimizing any impacts on the foraging success of whales if a rigorous analysis of the best available information suggests such impacts may occur. BOEM has made plausible assumptions in its analysis and has proposed mitigation measures based on its analysis of the best available information. BOEM is committed to applying the best available information throughout its environmental review.

Comment No.	Comment	Response
BOEM-2023-0011-0185-0006	We remain concerned about our ability to reach a "no jeopardy" conclusion in the pending ESA consultation for this project without incorporating mitigation measures designed to avoid and minimize impacts of construction and operation on North Atlantic right whales into the proposed action for consultation. We are currently reviewing the March 2022 draft biological assessment (BA) to determine if all of the information necessary to initiate consultation has been provided. The DEIS and BA should be consistent when addressing effects to North Atlantic right whales And drawing conclusions related to exposure to stressors including the risk of vessel strike; they currently are not. We look forward to working with you to incorporate any needed mitigation measures designed to avoid and minimize impacts of construction and operation on North Atlantic right whales throughout the ongoing ESA consultation to help BOEM ensure that the project is not likely to jeopardize the continued existence of the species.	The Final EIS and Final Biological Assessment (BA) have been revised and all conclusions are in alignment between the documents. The effects analysis of the BA includes conclusions regarding the construction, operation, and decommissioning of the proposed offshore wind project. BOEM, and SouthCoast through the Marine Mammal Protection Act (MMPA) Incidental Take Regulation (ITR) application process with NMFS, have proposed many mitigation and monitoring measures to avoid and minimize impacts on NARWs. Review of the best available information does not lead any analysis to conclusions that population-level impacts on NARWs, and jeopardy, are likely to result from the proposed action.
BOEM-2023-0011-0185-0007	We appreciate the consideration of a land-based alternative for the export cable corridor and we consider this to be the environmentally preferred alternative for the export cable route. Avoiding the Sakonnet River through a land-based cable route would reduce impacts to aquatic resources including important estuarine habitats and designated Habitat Areas of Particular Concern (HAPC) for juvenile Atlantic cod. The DEIS does not recognize or discuss the potential differences in anticipated impacts of construction within an estuarine environment compared with an offshore environment. Further the DEIS references outstanding surveys for the cable route that are necessary to evaluate how this alternative compares with the proposed action. The document appears to suggest without supporting evidence that cable installation within an estuarine environment would have the same effects as cable installation offshore and suggests that impacts to EFH finfish and invertebrates from avoiding construction in the Sakonnet River would "not [be]	The Final EIS (Section 3.5.2, *Benthic Resources*, and Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*) has been revised to include additional discussion of the difference in impacts on benthic and essential fish habitat (EFH) resources between the Proposed Action, which would lay cable in the Sakonnet River, and Alternatives C-1 and C-2, which would avoid the Sakonnet River by installing cable overland, including the difference in estuarine benthic disturbances. Following the release of the Draft EIS, SouthCoast Wind, at BOEM's request, commissioned two desktop studies using existing site-specific and regional data to inform BOEM's assessment of the Alternative C cable routes: *SouthCoast Wind BOEM Alternative C Geohazard Desktop Study* (TetraTech 2023) and *SouthCoast Wind BOEM Alternative C-1 Benthic Desktop Study* (INSPIRE 2023). The findings from these desktop studies have been incorporated into the Final EIS (principally Section 3.5.2, *Benthic Resources,* and Section

Comment No.	Comment	Response
	measurably different" from the proposed action. However the DEIS does not consider the unique features and value of the estuarine environment or how impacts of the project may vary along the alternative cable routes. Rather the analysis appears to discount the reduction in impacts to estuarine environments and associated fisheries that would be anticipated from the selection of the land-based alternative. We recommend that this analysis be revised to evaluate these unique estuarine features as further survey information becomes available.	3.5.5, *Finfish, Invertebrates, and Essential Fish Habiata*) and support BOEM's analysis of the cable routes. BOEM believes the information contained in these desktop studies, along with existing information that BOEM and SouthCoast Wind have already gathered (including a terrestrial archaeological desktop study [PAL 2022] and a marine archaeological desktop study [RCG&A 2022]; refer to Section 3.6.2, *Cultural Resourc*es) provides adequate information for BOEM to make an informed decision regarding the alternatives.
BOEM-2023-0011-0185-0008	In many sections of the DEIS there is little to no detailed analysis of the action alternatives or an evaluation of the differences in impacts between the action alternatives. The analysis for each of the action alternatives does not include consideration of the actual design parameters of the proposed action nor where these parameters are specifically located within the project area. The analyses are also very general and depict the lease area and surrounding waters as indistinguishable from any other parts of the continental shelf. This approach does not allow the reader to understand or identify any meaningful distinctions between the impacts of each of the action alternatives nor does it include a comparison of the impacts of the action alternatives to each other (beyond the affected footprint of the alternative) which is a key component of the EIS needed to inform decision making. The analysis remains solely focused on acreage of area impacted and does not consider other important factors such as the location and resources present in the affected area.	BOEM believes the analysis in the Draft EIS provided an appropriate level of detail and comparative analysis among alternatives for the public and decision-maker to distinguish the impacts between alternatives. The level of analysis and detail by alternatives is commensurate with other BOEM offshore wind EISs. However, to improve the discussion and understanding of the differences between alternatives, BOEM has added a Comparison of Alternatives section to each Chapter 3 resource section that compares the impacts among alternatives. Refer also to responses to comments by resource section regarding where BOEM has made revisions to the Final EIS based on specific NMFS comments about the alternatives analysis.
BOEM-2023-0011-0185-0009	Effects from the different alternatives will vary depending on the location of where the impact producing factors occur. However those variations in impacts are not captured in the DEIS and the analysis inaccurately assumes that fewer acres impacted is better without an assessment of potential trade-offs between alternatives. For example under Alternative F	BOEM agrees that the alternatives vary in impacts based on the location that the impact- IPFs would occur and has described those impacts to the extent the information is known and available. As it relates to Alternative F, BOEM has included additional discussion in various resource Final EIS sections (e.g., Section 3.5.2, *Benthic Resources*, and Section

Comment No.	Comment	Response
	the DEIS does not discuss the trade-offs between the installation of fewer cables and the long-term impacts to fish stocks from larval impingement associated with operation of the open loop cooling system of an HVDC converter station. This trade-off analysis may vary depending on the habitat types being impacted by cable installation and the location of the converter station but that is not discussed in the DEIS. We recognize that the EIS is a tool to inform decision making for this project; however the DEIS does not currently include the analysis and justification necessary to inform decisions related to alternatives and/or measures to reduce project impacts.	3.5.6, *Marine Mammals*) about the varying impacts and tradeoffs of Alternative F to the extent they are known. SouthCoast Wind has not yet identified the location of a potential second high-voltage direct current (HVDC) converter offshore substation platform (OSP) associated with the Project 2 interconnection, except that it would be located in the southern portion of the Lease Area. Additionally, the location of the cables that would not be installed under Alternative F (due to the reduction in the number of cables from five to three) is not known precisely, except that the amount of disturbance within the cable corridor would be reduced. Therefore, the acreage of disturbance is a useful metric in the absence of knowing the specific location of each individual cable.
BOEM-2023-0011-0185-0010	Similarly information on benthic characteristics to identify where and to what extent cable preparation activities will take place (trenching sand wave clearance boulder relocation cable protection etc.) is lacking and should be included in the FEIS.	BOEM believes the level of detail of potential area of cable preparation is sufficient and comparable to other offshore wind EIS documents. Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat,* has been revised to include a figure showing the location of boulder and sand wave clearance areas and anchoring locations. Additional project-specific detail is included in the EFH Assessment and a statement has been added to the Final EIS referring the reader to the EFH Assessment for more detail.
BOEM-2023-0011-0185-0011	Finally, the FEIS should include an evaluation of the most recent fishery data including fishing operations within state waters by state permitted vessels and impacts to shoreside support services to fully evaluate potential impacts and ensure proposed mitigation/compensation measures reflect all fishery operations and impacts. This information is needed to allow for a complete and thorough evaluation of each alternative in the FEIS.	Section 3.6.1.5 qualitatively assesses impacts on the shoreside support services, noting that the impacts on other fishing industry sectors, including seafood processors and distributors and shoreside support services, would be long term and minor to major, depending on the fishery in question. Further analysis of the socioeconomic impacts on fishing support industries is included in Section 3.6.3, *Demographics, Employment, and Economics*, and Section 3.6.4, *Environmental Justice*. Furthermore, BOEM is proposing a mitigation measure that would require SouthCoast Wind to conduct an analysis of impacts on

Comment No.	Comment	Response
		shoreside seafood businesses and to develop a plan to compensate for losses to shoreside businesses. BOEM has added this measure to the Final EIS (refer to Section 3.6.1-11 and Appendix G, Table G-2; CF-5).
BOEM-2023-0011-0185-0013	The DEIS contains sections where BOEM is relying on mitigation measures to reduce impacts but does not specify which of these measures if any are factored into the impact determination. In addition assumptions about the success of mitigation measures are made despite a lack of evidence or adequate detail regarding specific mitigation measures (e.g. fisheries and scientific survey impact mitigation). We recommend the FEIS address the anticipated impacts of the proposed action mitigation measures that are considered to be part of that action the effectiveness of these measures the expected impacts if mitigation methods are applied and the likelihood that such measures will be required and implemented. We ask that BOEM clarify if additional measures may be implemented upon COP approval but were not factored into the impact analysis.	As described in Final EIS Section 2.2, Section 3.2, and Appendix G, BOEM considers all SouthCoast Wind-committed measures as part of the Proposed Action and has factored them into all impact determinations. The applicant-committed measures are listed in Appendix G, Table G-1 and Attachment G-1 and are described in the analysis of each Chapter 3 resource section as appropriate. For example, Section 3.5.5.2 summarizes several of the applicant-committed measures applicable to the resource, and the analysis of the Proposed Action in Section 3.5.5.5 analyzes how these measures reduce impacts. Additional agency-proposed mitigation measures are identified in Appendix G, Table G-2. These measures are not part of the Proposed Action but are additional measures that BOEM may require to further avoid, minimize, or mitigate impacts. These measures are not factored into the impact determinations of each alternative because they are not part of the Project. Instead, within each Chapter 3 resource section, BOEM has included a *Proposed Mitigation Measures* section that describes and analyzes the effect of each agency-proposed measure. The analysis describes how the measures reduce impacts and whether the measures would change the impact determinations.
BOEM-2023-0011-0185-0014	We continue to have significant concerns related to the major impacts offshore wind development will have on our NOAA scientific surveys. The DEIS does not include any discussion on how these major impacts will be mitigated at the project level other than referencing the ongoing BOEM/NMFS survey mitigation efforts. However the mitigation strategy is not currently resourced and does not set requirements or standards with which projects must	BOEM has committed to working with the National Oceanic Atmospheric Administration (NOAA) to implement the Federal Survey Mitigation Strategy program (https://repository.library.noaa.gov/view/noaa/47925). Implementation of the program is pending. As discussions between BOEM and NOAA on implementation of the program continue, specific details of appropriate mitigation measures will be added to the environmental analysis. In

Comment No.	Comment	Response
	comply. In order to minimize the major adverse impacts expected on scientific surveys we recommend mitigation measures be required and implemented before development moves forward consistent with our joint survey mitigation efforts. We will continue to work with you to ensure these details can be included in the FEIS.	Final EIS Section 3.6.7.10, *Proposed Mitigation Measures*, BOEM has indicated that the individual survey mitigation plans associated with the NOAA and BOEM Federal Survey Mitigation Program have not been developed and funding is not currently available to support survey mitigation plans to date.
BOEM-2023-0011-0185-0015	EIS Section: Global PDF Page: Global Comment: Cumulative Effects of Alternative A (No Action) - All anticipated IPFs should be fully analyzed for all resources. There are varying levels of concluding statements for each IPF under the cumulative effects of Alternative A (No Action) across the resource sections. Without a clear concluding statement (including minor moderate or major; beneficial or adverse) for the impacts of each individual IPF it is difficult for the reader to fully understand the makeup of the overall impact conclusion for the cumulative effects of the No Action alternative.	The Final EIS has been updated to ensure an impact rating is included for each IPF considered under the *Cumulative Effects of the No Action Alternative* analysis for each Chapter 3 resource area.
BOEM-2023-0011-0185-0016	Executive Summary EIS Section: List of Tables PDF Page: 6 Comment: Table ES-1 and ES-2 should be listed here. EIS Section: List of Tables PDF Page: 12 Comment: Figure ES-1 should be listed here. Please add the following sentence that has been dropped "In addition NMFS has an independent responsibility to comply with NEPA and will rely on the information and analyses in BOEM's final EIS after independent review to fulfill its NEPA obligations." preceding the following sentence: "NMFS intends to adopt the Final EIS if after independent review and analysis it determines the Final EIS to be sufficient to support the authorization."	The tables and figure in the Executive Summary have been added to the Table of Contents in the Final EIS. The requested sentence regarding NMFS's independent responsibility to comply with NEPA has been added to the Executive Summary.
BOEM-2023-0011-0185-0017	EIS Section: ES.1 PDF Page: 22 Comment: The first sentence mentions the NEPA regulations but cites the U.S. Code for NEPA itself. The proper citation would be: (40 CFR 1500-1508).	The sentence is referencing the NEPA statute and does not mention the implementing regulations. The U.S. Code citation was retained.
BOEM-2023-0011-0185-0018	EIS Section: ES.4.4 PDF Page: 30 Comment: NMFS has proposed several changes to Alternative D in the cover letter	BOEM believes the information regarding hydrodynamic effects included in the description of Alternative D in

Comment No.	Comment	Response
	that accompanies this table. However, if Alternative D remains as is this Executive Summary section should present a description of the alternative. The discussion of the modeling conducted appears misplaced and does not describe the alternative. Accordingly please remove sentences 3 through 6 specifically the following words: "However modeling of the full build out of the entire southern New England lease areas indicates that minor local changes to the physical hydrodynamic features may occur on the western side of Nantucket Shoals adjacent to the BOEM lease areas (Johnson et al. 2021). Based on best available science, BOEM believes there is a lack of conclusive evidence that the removal of proposed turbine locations in the northeastern portion of the Lease Area would measurably lessen these minor impacts on the hydrodynamic features. If the potential hydrodynamic effects are consistent with the modeling of the southern New England lease areas and other hydrodynamic studies of wind facilities in the North Sea the effects would be local to the immediate vicinity of the turbine array and not extend to Nantucket Shoals. If the potential hydrodynamic effects are as extensive as potential wind wakes that could extend tens of kilometers under stable conditions which has not been demonstrated then the removal of turbines would not remove this potential range of effects from extending far enough from the turbine array to overlap with Nantucket Shoals. Nonetheless…" NMFS has made the same comment in Chapter 2 where the same language appears.	Executive Summary Section 4.4 and Chapter 2, Section 2.2.4 provides important context for why the alternative was identified, developed, and analyzed in the EIS. BOEM has added additional information to the Final EIS to describe the findings from the 2024 NASEM study on hydrodynamic impacts in the Nantucket Shoals region, which provides further context for the purpose and intent of the alternative.
BOEM-2023-0011-0185-0019	EIS Section: ES.5 PDF Page: 33 Comment: Please change to the title of the table to reflect that it accurately reflects that impacts do include mitigation. ES.5 37 Comment: The footnote for the table indicates that light green is used for boxes that are "negligible or beneficial to any degree" but there is no light green shown in the table.	Final EIS Table ES-2 and the text preceding the table was revised to clarify that the impacts are with no agency-proposed mitigation. The Proposed Action and action alternatives analyzed in the EIS assume implementation of all applicant avoidance, minimization, and mitigation measures (AMMs).

Comment No.	Comment	Response
	Recommend removing this from the footnote to eliminate confusion.	The footnote for Table ES-2 was updated to remove light green as the color was not used in the table.
BOEM-2023-0011-0185-0020	Chapter 2: Alternatives EIS Section: 2.1 PDF Page: 50 Comment: In the fourth paragraph there is no consultation under the MMPA. NMFS suggests correcting the sentence by replacing it with: "Consultations under ESA Section 7 and the Magnuson–Stevens Fishery Conservation and Management Act (MSA) as well as the submission for and issuance of other necessary permits and authorizations under applicable statutes including the MMPA may result in additional measures or changes to these measures."	Final EIS Section 2.1 has been revised as suggested.
BOEM-2023-0011-0185-0021	EIS Section: 2.1 PDF Page: 50 Comment: Please modify the fourth paragraph to indicate that the applicant-proposed mitigation measures listed in Table G-1 will be included in the proposed action and that additional mitigation and monitoring measures that BOEM may require are listed in Table G-2. (See Appendix G pp 1-2).	Final EIS Section 2.1 has been revised as suggested.
BOEM-2023-0011-0185-0022	EIS Section: 2.1 PDF Page: 50 Comment: NMFS advises that if any mitigation measures are analyzed in the impact analysis and they influence the impact determinations and selection of an alternative those measures must be mandatory in the preferred and selected alternative for a proper impacts analysis.	Comment acknowledged.
BOEM-2023-0011-0185-0023	EIS Section: 2.1.4 PDF Page: 67 Comment: NMFS has proposed several changes to Alternative D in the cover letter that accompanies this table. However if Alternative D remains as is this section should present a description of the alternative. The discussion of the modeling conducted appears misplaced and does not describe the alternative. Accordingly please remove sentences three through six specifically the following words: "However modeling of the full build out of the entire southern New England lease areas indicates that minor local changes to the physical hydrodynamic features may occur on the western side of	Please refer to response to Comment BOEM-2023-0011-0185-0018.

Comment No.	Comment	Response
	Nantucket Shoals adjacent to the BOEM lease areas (Johnson et al. 2021). Based on best available science BOEM believes there is a lack of conclusive evidence that the removal of proposed turbine locations in the northeastern portion of the Lease Area would measurably lessen these minor impacts on the hydrodynamic features. If the potential hydrodynamic effects are consistent with the modeling of the southern New England lease areas and other hydrodynamic studies of wind facilities in the North Sea the effects would be local to the immediate vicinity of the turbine array and not extend to Nantucket Shoals. If the potential hydrodynamic effects are as extensive as potential wind wakes that could extend tens of kilometers under stable conditions which has not been demonstrated then the removal of turbines would not remove this potential range of effects from extending far enough from the turbine array to overlap with Nantucket Shoals. Nonetheless…" NMFS has made the same comment on the Executive Summary where the same language appears.	
BOEM-2023-0011-0185-0024	EIS Section: 2.1.4 PDF Page: 69 Comment: The caption for Figure 2-7 incorrectly states that Alternative D is the removal of six WTGs. The correct language is: "up to six WTGs." This error also appears in Sections 3.5.3.7 and 3.5.6.7.	Text in Final EIS Figure 2-7, Section 3.5.3.7, and Section 3.5.6.7 has been corrected to "up to six WTGs."
BOEM-2023-0011-0185-0025	EIS Section: 2.1.6 PDF Page: 76 Comment: Please provide more detailed information about Alternative F including information on the habitat types and species of importance in the Muskeget Channel how much area of seabed disturbance would be avoided as well as locations (maps) of the HVDC converter OSPs and planned offshore export cable routes.	SouthCoast Wind has not yet identified the location of a potential second HVDC converter OSP associated with the Project 2 interconnection, except that it would be located in the southern portion of the Lease Area. It would be impracticable and imprudent for BOEM to select the location of the OSP for Alternative F as the selection of an OSP location is based upon geotechnical data, offtake agreements, material/equipment procurement process, and other factors to which BOEM is not privy. The location of the cables that would not be installed under Alternative F (due to the reduction in the number of cables from five to three) is also not precisely known except that all cables would be

Comment No.	Comment	Response
		within the Falmouth Export Cable Corridor (ECC) as mapped in Chapter 2, Figure 2-1. Additional information about habitat types, including complex habitat in the Muskeget Channel, within the Falmouth ECC where impacts could be reduced under Alternative F has been added to the relevant Chapter 3 resource sections in the Final EIS, including Section 3.5.2, *Benthic Resources*, and Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*.
BOEM-2023-0011-0185-0026	EIS Section: 2.2 PDF Page: 78 Comment: In the row of Table 2-3 for the alternative "WTG generation capacities that analyze different deployment ranges of WTG MW generation capacities" the justification for dismissal states that the developer has 1275 MW in existing offtake agreements. Earlier in the document in sections ES.2 and 1.2 it is stated that the developer has PPAs for 804 and 400 MW - for a total of 1204 MW. Please clarify the reason for the numerical difference or explain the difference between PPAs and offtake agreements.	In light of SouthCoast Wind's bid into the Massachusetts 83C IV and multi-state solicitations, selection of WTG design(s) with specific nameplate capacities cannot be deferred until the Record of Decision (ROD) under the current market conditions. Specifically, waiting until the ROD is issued for the government to decide whether to select a turbine capacity for Project 1 of the Project would undermine the integrity of SouthCoast Wind's bid and a selection of a WTG outside of SouthCoast Wind's Project Design Envelope (PDE) would render the Project infeasible by invalidating a potential award, which includes WTG specifications and economic assumptions based on the capacity of the WTG and creating delays that would prevent the ability for SouthCoast to meet the required capacity for Project 1. The needed capacity for Project 1 into the NE Multistate Solicitation is 1,275 megawatts (MW).
BOEM-2023-0011-0185-0027	EIS Section: 2.2 PDF Page: 79 Comment: In the row of Table 2-3 for the alternative "Preclude the development of WTGs within a 20-kilometer buffer of the Nantucket Shoals 30-meter isobath" the justification for dismissal states that the developer has 1275 MW in existing offtake agreements. Earlier in the document in sections ES.2 and 1.2 it is stated that the developer has PPAs for 804 and 400 MW - for a total of 1204 MW. Please clarify the reason for the numerical difference or explain the difference between PPAs and offtake agreements.	BOEM determined this alternative is economically infeasible and not consistent with the Project purpose and need to provide up to 2,400 MW of clean, renewable wind energy to the northeast United States, including Massachusetts, Connecticut, and/or Rhode Island, which each have existing state offshore wind procurement laws in place as well as decarbonization goals and targets. Under this alternative, 53 WTGs would be eliminated, leaving 94 WTG and 2 OSP positions; 85 WTGs and 1 OSP, out of the remaining 96 positions would be needed for Project 1, assuming the use of a 15 MW WTG model. BOEM determined the use of a 15 MW

Comment No.	Comment	Response
		WTG for Project 1 is a reasonable assumption based on the PDE in the Construction and Operations Plan (COP) and Request for Information (RFI) responses from SouthCoast Wind. SouthCoast Wind needs the 85 WTGs for Project 1 to achieve the 1,275 MW in planned offtake that SouthCoast Wind has bid into the Massachusetts 83C IV and multi-state Massachusetts, Rhode Island, and Connecticut solicitation for up to 6,000 MW of offshore wind power. SouthCoast Wind confirmed that their Project 1 bid includes the shallowest WTG positions in their lease (which also overlap with the positions that are closest to Nantucket Shoals and to shore) because they provide the most cost-competitive rates for consideration for an award. Consequently, if BOEM were to relocate the majority of the WTG positions for Project 1 into deeper waters it would invalidate SouthCoast Wind's bid.
BOEM-2023-0011-0185-0028	EIS Section: 2.2 PDF Page: 79 Comment: In regards to the "Preclude the development of WTGs within a 20-kilometer buffer of the Nantucket Shoals 30-meter isobath" alternative in Table 2-3 the text notes that only 2/3 of full geotechnical surveys have been completed and due to the positions impacted by the 20-km buffer SouthCoast is not able to analyze and design foundations in time in the remaining 1/3 of the lease area to meet the deadlines in their Massachusetts PPAs as rationale for why the alternative was rejected. Additionally, the rationale also states that 53 WTGs would be eliminated by the 20-km buffer but NMFS analysis shows that 49 WTGs would be removed. At 15-MW per WTG this is 60 MW that should be accounted for in the text. Lack of complete survey coverage in a timely fashion should not preclude feasible alternatives from consideration. The text also states that SouthCoast's primary goal includes interconnecting at POIs that have a maximum capacity of 1200 MW. This goal can still be achieved with the 20-km buffer as there would still be a suitable number of positions left to fulfill their 1200 MW PPA with MA.	NMFS requested that BOEM consider an alternative that would prohibit installation of WTGs within a 20-kilometer buffer of the Nantucket Shoals 30-meter isobath to reduce potential impacts on this important foraging area for aquatic species, such as the NARW and sea ducks. Under this alternative, 53 WTGs would be eliminated, leaving 94 WTG and 2 OSP positions; 85 WTGs and 1 OSP, out of the remaining 96 positions would be needed for Project 1, assuming the use of a 15 MW WTG model. BOEM determined the use of a 15 MW WTG for Project 1 is a reasonable assumption based on the PDE in the COP and RFI responses from SouthCoast Wind. SouthCoast Wind needs the 85 WTGs for Project 1 to achieve the 1,275 MW in planned offtake that SouthCoast Wind has bid into the multi-state Massachusetts, Rhode Island and Connecticut solicitation for up to 6,000 MW of offshore wind power. Under this alternative, for Project 2 SouthCoast would only have 9 WTGs and 1 OSP left with a total nameplate capacity of 162 MW, assuming 18 MW WTGs were used. BOEM determined the use of an 18 MW WTG for Project 2 is a reasonable assumption based on the PDE in the

Comment No.	Comment	Response
	Lastly the rationale also notes that SouthCoast is competing for PPAs with NY RI and MA. However, SouthCoast did not compete for RI or NY in either recent RFP. MA has not issued their RFP yet but notably Commonwealth Wind (which previously withdrew from its MA PPA) will also be bidding against SouthCoast among others. Thus, it is conceivable that SouthCoast may be selected for the MA PPA but it is not certain and this also has implications for other projects (i.e. Commonwealth Wind) and that rationale should be applied consistently across the NEPA process. Given this the rationale provided is not adequate justification for dismissal of an alternative as SouthCoast Wind can technically meet their PPA with MA and their goal of interconnecting with a POI with 1200 MW capacity.	COP and RFI responses from SouthCoast Wind. The smallest bid for which a New England state has sought in a procurement since 2022 is 600 MW for Rhode Island (State of Rhode Island General Assembly 2022). A 162 MW project falls well below this amount and the multi-state solicitation between Rhode Island, Massachusetts and Connecticut are only seeing bids that are 800 MW and above with the states trending toward requesting projects that are over 1,000 MW. Furthermore, BOEM and the National Renewable Energy Laboratory (NREL) conducted technical-economic modeling of Projects 1 and 2 and found this alternative to be economically infeasible due to uneconomical increases in the Levelized Cost of Energy (LCOE). Consequently, this alternative is not reasonable under NEPA because it is not consistent with the purpose and need, nor SouthCoast Wind's primary goals, and is not economically feasible or practicable and would, therefore, be equivalent to the No Action Alternative.
BOEM-2023-0011-0185-0029	EIS Section: 2.2 PDF Page: 79 Comment: In the row of Table 2-3 for the alternative "Preclude the development of WTGs within a 20-kilometer buffer of the Nantucket Shoals 30-meter isobath" the NMFS letter was focused on right whales and not sea ducks and other aquatic species (although the alternative could benefit other species).	This table characterizes the area as being used by multiple species.
BOEM-2023-0011-0185-0030	EIS Section: 2.4 PDF Page: 87 Comment: Please confirm that Table 2-4 represents impacts "with no mitigation." Section 2.1 states that mitigation proposed by the applicant is included in the proposed action and the analysis under Chapter 3 utilizes the implementation of mitigation when determining impact levels. If the levels in Table 2-4 do not represent the findings in the later analysis please indicate that and provide a rationale. Please ensure the title of the table on the following page reflects any changes.	Final EIS Table 2-4 and the text preceding the table was revised to clarify that the impacts are with no agency-proposed mitigation. As stated in Section 2.1, the Proposed Action and action alternatives analyzed in the EIS assume implementation of all applicant-proposed AMMs.

Comment No.	Comment	Response
BOEM-2023-0011-0185-0031	EIS Section: 2.4 PDF Page: 90 Comment: In the row for "3.5.6 Marine Mammals" in the boxes for the Proposed Action and other action alternatives the summary text states that there are "potentially beneficial impacts." Please classify the level of these impacts as negligible minor moderate or major for the Proposed Action and each action alternative. See similar comment for section 3.5.6.	Final EiS Table 2-4 has updated to indicate there would be “minor beneficial impacts.” Similar changes were also made in Section 3.6.5.
BOEM-2023-0011-0185-0032	EIS Section: 2.4 PDF Page: 90 Comment: Alternative F: Consider noting that this could have a potential beneficial impact to harbor seal pupping on Muskeget Island.	Text regarding the potential for a reduction in impacts on harbor seal pupping under Alternative F has been added to the analysis of marine mammals in Section 3.5.6.6. This information was not included in Section 2.4 because that section is intended to present only a high-level summary of impacts.
BOEM-2023-0011-0185-0033	Section 3.1-3.3 (IPFs Mitigation and Definition of Impact Levels) EIS Section: 3.2 PDF Page: 101 Comment: After the end of the 2nd sentence (after "in this chapter.") please add language along the lines of: "If any mitigation measures are analyzed in the impact analyses and those measures influence the impact determinations those measures will be required as part of the alternative." Any mitigation and monitoring terms that influence the impact conclusions and final agency decision need to be committed measures in order for the assumptions and conclusions of the analysis to be accurate. They are not optional measures. This comment has been made previously in other EISs.	Final EIS Section 3.2 has been revised to incorporate language similar to the text suggested in the comment.
BOEM-2023-0011-0185-0034	EIS Section: 3.2 PDF Page: 101 Comment: Please change the 3rd sentence to read "In addition other mitigation measures may be required through completion of consultations, authorizations, and permits with respect to several environmental statutes such as the MMPA, Section 7 of the ESA, or the MSA." The MMPA process is not a consultation and the recommended language corrects the sentence.	Final EIS Section 3.2 has been revised as suggested in the comment.
BOEM-2023-0011-0185-0035	Section 3.5.2: Benthic Resources EIS Section: 3.5.2 PDF Page: Global Comment: For each alternative please provide a	Under the analysis of Alternatives C, D, E, and F, separate IPF headings were not considered necessary if the analysis could

Comment No.	Comment	Response
	separate subheading and complete discussion/evaluation for each IPF. Avoid using one large paragraph with minimal information for each IPF as this provides incomplete and confusing analyses.	be more concisely described without the headings or the IPF being discussed was apparent from the context. This approach is consistent with other BOEM offshore wind EISs.
BOEM-2023-0011-0185-0036	EIS Section: 3.5.2 PDF Page: Comment: It is unclear if the mitigation measures discussed are planned or confirmed to be implemented. Using language such as "may" or "potentially" when discussing implementation of mitigation or minimization measures is misleading. Additionally potential or possible mitigation measures should not be used as justification for reduced impacts. Only mitigation measures that are committed to by BOEM and the developer during the Project's lifespan should be discussed or used as part of impact evaluations.	BOEM has described all applicant measures in the EIS as proposed by SouthCoast Wind in the COP. Agency-proposed measures are included in Appendix G, Table G-2. BOEM has considered all public comments on the Draft EIS and has made changes to the mitigation measures as appropriate, which is reflected in the Final EIS.
BOEM-2023-0011-0185-0037	EIS Section: 3.5.2 PDF Page: Global Comment: Please ensure impact evaluations are specific to the Project and the alternative and do not simply reference information presented for the No Action alternative which is non-specific and encompasses much larger and often much different habitats and species. For example under Impacts of Alternative B Accidental Releases IPF an evaluation of the potential impact of invasive species releases on benthic resources should be provided which are specific to this Project area and this alternative. Simply stating that impacts will be similar to the No Action Alternative does not provide a clear analysis of effects from this specific project as it does not consider the habitat types and species in this Project area that may be affected.	The types of species to be spread or where they could be released based on accidental releases cannot be known with certainty, and no specific impacts can be stated with confidence other than what is described in the No Action Alternative. The *accidental releases* IPF in Section 3.5.2, *Benthic Resources*, is also consistent with the *accidental releases* IPF in other offshore wind EISs, including Revolution Wind and Ocean Wind 1. The *presences of structures* IPF is a good example of where the Proposed Action does not refer to the No Action Alternative for invasive species. In EIS Section 3.5.5.5, the subtidal invasive species known within the region are laid out and one species (D. vexillium) is detailed in its impact and expands on its documented spread to WTG and scour protections of other offshore wind farms.
BOEM-2023-0011-0185-0038	EIS Section: 3.5.2 PDF Page: Global Comment: At this time concluding: "The impacts resulting from individual IPFs associated with construction and installation O&M and decommissioning of the Project under [Alternatives C-F] would be similar to those described under the Proposed Action" is unsupported and the necessary level of	Under the analysis of Alternatives C, D, E, and F, separate IPF headings were not considered necessary if the analysis could be more concisely described without the headings or the IPF being discussed was apparent from the context. This approach is consistent with other BOEM offshore wind EISs. BOEM has also reviewed the impact conclusions for each

Comment No.	Comment	Response
	information to determine this is not provided. Site survey information and individual analyses for each IPF are missing. Additionally there are measureable impact reductions to benthic habitats from in these alternatives which would result in different overall impacts from to those of the Proposed Action. Currently the conclusion that impacts for Alternatives C-F are the same as the Proposed Action is unsupported and dilutes each alternative and bolsters the Proposed Action. All alternatives should receive the same level of robust analysis and consideration under NEPA. Please address.	alternative and believes they are appropriate and supported by the analysis. Alternatives C-F were developed to minimize specific environmental impacts in certain geographies, such as minimizing cable emplacement in the Muskeget Channell. While impacts may be reduced, the 149 WTG/OSP positions, interarray cables, export cables would still be installed and affect the benthic habitat so a change in the overall impact level is not supported. Regarding the analysis of Alternative C, BOEM has updated the analysis with additional desktop studies performed by SouthCoast Wind, which include a benthic desktop study and a geohazard study. To further describe the difference in impacts among the alternatives, BOEM has added Section 3.5.2.10, *Comparison of Alternatives*, to the Final EIS.
BOEM-2023-0011-0185-0039	EIS Section: 3.5.2.1 PDF Page: Global Comment: Any identified HAPC should be explicitly identified mapped and described in the Affected Environment section even if it is referenced later in the chapter. This includes in the Lease Area Sakonnet River export cable corridors landfall areas and any other areas that may be impacted by the proposed action.	All sensitive habitats are identified in Final EIS Section 3.5.5.1, *Essential Fish Habitat*. This section contains tables describing Habitat Types by Project Component – Offshore/Onshore Export Cable with acreage of each habitat type found in each EEC (Tables 3.5.5-2, 3.5.5-3, 3.5.5-4 and 3.5.5-5). A cross reference to these tables has been added to Section 3.5.2.1. Maps depicting inshore submerged aquatic vegetation (SAV) habitat for potential cable landing sites in Brayton Point and Falmouth are included in COP Appendix K (Seagrass and Macroalgae Report) Section 4.3 in Figures 4-1, 4-2, 4-3, and 4-4.
BOEM-2023-0011-0185-0040	EIS Section: 3.5.2.1 PDF Page: 180 Comment: The "three gravelly samples" observed should include further discussion and identification of location.	Exact coordinates and a brief location description has been added to the Final EIS Section 3.5.2.1, *Inshore Project Area.*
BOEM-2023-0011-0185-0041	EIS Section: 3.5.2.3 PDF Page: 182 Comment: Under Accidental Releases please provide a source for the following information: "The chemicals with potential to sink or dissolve rapidly are predicted to dilute to non-toxic levels before they would reach benthic resources."	Source (Vineyard Wind 1 EIS) has been added to the text.

Comment No.	Comment	Response
BOEM-2023-0011-0185-0042	EIS Section: 3.5.2.3 PDF Page: 190 Comment: Presence of Structures IPF: There is significant information lacking on the potential adverse impacts of newly introduced artificial material on benthic communities such as changes in oxygen and nutrient cycling heterotrophic and autotrophic community structure and changes to bacterial composition of sediment (Degraer et al. 2020; Tong et al. 2022). The "reef effect" of the proposed structures is currently described as a net benefit but there is also potential for artificial structures to cause adverse impacts to benthic ecosystems and these topics should be thoroughly addressed and evaluated.	Information regarding the impacts imposed by the presence of structures can be found in EIS Section 3.5.2.5, *Presence of structures*. In this section, BOEM discusses the invasive species present and how they can colonize novel hard bottom substrate like WTGs. Impacts from Degraer et al. (2020) are consistent with what is discussed in the Final EIS (net positive on biodiversity, increased deposition of fecal matter from biofouling community, and novel hard bottom substrate from WTG and scour protection could act as steppingstone habitat for invasive species spread). Findings from Tong et al. (2022) on bacterial activity and community composition on novel artificial structures compared to 10-year-old artificial structures and control sites is incorporated into Section 3.5.2.5.
BOEM-2023-0011-0185-0043	EIS Section: 3.5.2.5 PDF Page: 195-196 Comment: EMF IPF: This section should tie together the EMF levels studied in the cited references with the EMF levels expected by the project. Many of the referenced effects could adversely affect benthic species in the analysis area.	Information in Section 3.5.2.5, *EMF* has been expanded to indicate that the intensity of electromagnetic field (EMF) levels on benthic species in cited studies is much higher than predicted production levels for offshore wind cabling. Further reiteration is available and referenced in EIS Section 3.5.2.3 *Cumulative Impacts of No Action Alternative*.
BOEM-2023-0011-0185-0044	EIS Section: 3.5.2.5 PDF Page: 196 Comment: EMF IPF: There has been much more research on this topic since Exponent 2018 which was previously cited. The text suggests that if the animal leaves the area then it would no longer be affected by EMFs. Which area does this refer to the entire wind farm and cable corridor? Please clarify.	BOEM states that EMFs produced during operation occur from the interarray and export cabling. Section 3.5.2.5 describes measures SouthCoast Wind has committed to minimizing EMFs, including electric shielding and cable burial. Scientific literature stated in this section also points to the potential impacts of EMFs on marine mobile fauna.
BOEM-2023-0011-0185-0045	EIS Section: 3.5.2.5 PDF Page: 196 Comment: EMF IPF: The conclusion that impacts will be “localized long-term and minor” should be reconciled with the literature cited in this section which provides evidence for large adverse impacts on predator/prey interactions movement navigation avoidance or attraction behaviors and physiological and developmental processes.	The impacts were deemed as localized long term and minor because the cables are intended to be fully buried. Hence, maximal exposure to EMFs would only occur around areas where they are uncovered (land/sea interface) or if they were uncovered by sediment transport due to waves and storm events. Most literature states that there is little to minor effects on invertebrates. Most studies on fish or electrosensitive species like elasmobranchs (sharks, skates, rays) are conducted in laboratory settings in which these

Comment No.	Comment	Response
		organisms are exposed to EMFs at intensities that are two to three orders of magnitude above maximal measured EMF intensity from submarine cables (Normandeau et al. 2011). For example, Normandeau et al. (2011) measured EMF intensities at varying horizontal distances, and varying cable burial depths from energized HVAC and HVDC cables and found that 0m away and 0m beneath the sediment, HVAC and HVDC produced 7.85 µT and 78.27 µT EMFs respectively. At 4 meters away (horizontally) from the cables, the EMF intensity drops to 1.47 µT and 5.97 µT for HVAC and HVDC cables and burying these cables 5 meters beneath the surface decrease the intensities further to 0.35 µT and 2.73 µT for HVAC and HVDC cables. Since this project aims to bury interarray and export cables to a target depth of 6 feet (1.8 meters), according to Normandeau et al. (2011), the intensity of EMFs felt by marine life would be minimal.
BOEM-2023-0011-0185-0046	EIS Section: 3.5.2.5 PDF Page: 197 Comment: Cable Emplacement IPF: When discussing impacts to habitat (particularly SAV/eelgrass) please include a discussion of amount and location of HAPC that would be impacted by each of the cable emplacement methods.	All sensitive habitats are identified in Final EIS Section 3.5.5.1, *Essential Fish Habitat*. This section contains tables describing Habitat Types by Project Component – Offshore/Onshore Export Cable with acreage of each habitat type found in each EEC (Tables 3.5.5-2, 3.5.5-3, 3.5.5-4 and 3.5.5-5). A cross reference to these tables has been added to Section 3.5.2.1. A map of the Falmouth inshore SAV for alternative and potential landing sites is also referenced in Final EIS Section 3.5.2.1, *Inshore Project Area* (COP Appendix K, Figure 6, 7 and Figure 5-1). No SAV were detected offshore and, therefore, are only mapped in the nearshore maps for the sea to land ECC maps.
BOEM-2023-0011-0185-0047	EIS Section: 3.5.2.5 PDF Page: 200 Comment: Noise IPF: Analysis is insufficient. Please review relevant literature including the following and the references therein: Sole et al. 2023 (doi: 10.3389/fmars.2023.1129057) (Hyperlink: https://www.frontiersin.org/articles/10.3389/fmars.2023.1129057/full) Hawkins et al. 2021 (doi.org/10.1121/10.0004773) (Hyperlink:	The impact of noise is analyzed in greater detail in Section 3.5.2.3, *Noise*. The suggested references were added to the discussion in Final EIS Section 3.5.2.3, *Noise*. Impacts of anthropogenic sound on invertebrate taxa were noted from Sole et al. (2023). References to the analysis of particle motion sound and its relevance to benthic invertebrates from Hawkins and Popper (2017), and Popper and Hawkins (2018)

Comment No.	Comment	Response
	http://doi.org/10.1121/10.0004773); Hawkins and Popper 2017 (doi: 10.1093/icesjms/fsw205) (Hyperlink: https://academic.oup.com/icesjms/article/74/3/635/2739034?login=false); Popper and Hawkins 2018 (doi.org/10.1121/1.5021594) (Hyperlink: http://doi.org/10.1121/1.5021594).	were added to the text. WTGs generation of vibration as noted in Hawkins et al. (2021) was included in the review.
BOEM-2023-0011-0185-0048	EIS Section: 3.5.2.5 PDF Page: 200 Comment: Noise IPF: An analysis of noise from G&G activities and turbine operation should be included here. The analysis should include a discussion of both sound pressure and particle motion as well as substrate vibration for all aspects of the project the involve noise.	The noise related IPF associated with all stages of wind farm development and potential impacts on benthic resources are introduced in Alternative A and are expected to be similar for Alternative B. A note has been made in Final EIS Section 3.5.2.5, *Noise*, to clarify this. Section 3.5.2.3, *Noise* contains a discussion of geophysical and geotechnical (G&G) activities and turbine operation as well as sound pressure, particle motion, and substrate vibration.
BOEM-2023-0011-0185-0049	EIS Section: 3.5.2.5 PDF Page: 201 Comment: Presence of Structures IPF: Analysis is insufficient. This analysis should include a discussion of FAD (fish aggregating device) effects; artificial reef effects; modification of the prey field and diet for upper level predators the potential for structures to facilitate the establishment and range expansion of non-native species; local and broad scale wind-wake effects on larval transport etc. Please also include relevant supporting literature to support statements made. There is a growing body of knowledge on these topics and the majority of this information is missing from the analysis.	Section 3.5.2.3, *Presence of structures* has been revised to include additional analysis and references regarding effects related to nonnative species. A discussion of fish aggregating around WTGs, artificial reef effects, wind-wake effects, and vertical mixing/hydrodynamic impacts of structures are discussed extensively discussed in the finfish, invertebrates, and EFH analysis in Section 3.5.5.5, *Presence of Structures*.
BOEM-2023-0011-0185-0050	EIS Section: 3.5.2.5 PDF Page: 201 Comment: Presence of Structures IPF: Wind wakes and their effects on hydrodynamics may extend 10s of km from the wind farm. This could affect larval transport the thermal environment primary and secondary production and other important processes. These impacts should be analyzed and the following literature should be included in the analysis: Christiansen et al. 2022 (doi: 10.3389/fmars.2022.818501) (Hyperlink: https://www.frontiersin.org/articles/10.3389/fmars.2022.81	Final EIS Section 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*, has been revised to include additional analyses of wind wake and hydrodynamic effects, including citing Christiansen et al. (2022), Daewel et al. (2022), and Dorrell et al. (2022). Within the benthic resources section, a cross reference has been added to Section 3.5.5 to refer the reader to these more detailed analyses.

Comment No.	Comment	Response
	8501/full); Daewel et al. 2022 (doi.org/10.1038/s43247-022-00625-0) (Hyperlink: http://doi.org/10.1038/s43247-022-00625-0); Dorrell et al. 2022 (doi: 10.3389/fmars.2022.830927) https://www.frontiersin.org/articles/10.3389/fmars.2022.830927/full.	
BOEM-2023-0011-0185-0051	EIS Section: 3.5.2.5 PDF Page: 201 Comment: Please provide a citation for the following sentence: "The addition of new substrate could provide stepping stones for invasive species colonization." The work by Coolen et al. 2020 (DOI: 10.1111/mec.15364) (Hyperlink: https://onlinelibrary.wiley.com/doi/10.1111/mec.15364) would be a strong citation.	The suggested citation (Coolen et al. 2020) was added to Section 3.5.2.5.
BOEM-2023-0011-0185-0052	EIS Section: 3.5.2.6 PDF Page: 205 Comment: In this section BOEM provides a quantitative measurable amount of impacts to benthic resources that would be reduced through this alternative. This includes avoidance of impacts to mixed or complex hard bottom EFH live crepidula reefs and crepidula shell hash all which are important habitats which many species depend on. However a few paragraphs later BOEM states that "the long-term effects of avoiding construction through these habitats is difficult to quantify and benthic habitats would likely recover within a few years after construction; therefore impacts would be temporary." NMFS disagrees that effects would be temporary as it is contrary to available information on recovery times for complex habitats. Impacts to complex habitats are expected to result in long-term or permanent impacts. The impacts determination language should more accurately represent the information presented and available literature related to recovery of complex habitats.	Final EIS Section 3.5.2.6 has been revised to indicate that impacts associated with cable emplacement in complex or sensitive habitats such as areas with *Crepidula* reefs, cobbles, or boulders, may impose long-term or permanent impacts where these habitats are present within the cable route.
BOEM-2023-0011-0185-0053	EIS Section: 3.5.2.6 PDF Page: 205 Comment: In this section BOEM states that "Alternative C-1 and 4 miles [6.4 kilometers] under Alternative C-2) have not been surveyed and therefore the specific benthic resources that would be	SouthCoast Wind, at BOEM's request, commissioned two desktop studies in 2023 using existing site-specific and regional data to inform BOEM's assessment of the Alternative C cable routes: *SouthCoast Wind BOEM Alternative C*

Comment No.	Comment	Response
	affected are not known at this time but are anticipated to be similar to the benthic resources found along the Proposed Action's cable corridor given the proximity of the routes." More information should be provided on the anticipated timing of these surveys including if BOEM plans to incorporate the information into the FEIS. Any currently available information should also be used to further characterize the cable routes. It is also unclear how these cable routes are considered similar to the proposed action if they avoid estuarine habitats.	*Geohazard Desktop Study* (TetraTech 2023) and *SouthCoast Wind BOEM Alternative C-1 Benthic Desktop Study* (INSPIRE 2023). The findings from these desktop studies have been incorporated into the Final EIS, Section 3.5.2.6, and BOEM believes the information contained in these desktop studies, along with existing information that BOEM and SouthCoast Wind have already gathered, provides adequate information for BOEM to make an informed decision regarding the alternatives. Text has also been added on the decrease in estuarine benthic disturbance under Alternative C.
BOEM-2023-0011-0185-0054	Section 3.5.4: Coastal Habitat and Fauna EIS Section: 3.5.4 PDF Page: Global Comment: Please include accidental releases (including marine debris oil and gas and invasive species) as part of your impacts analysis for all alternatives.	The coastal habitat and fauna geographic area analysis is defined in Section 3.5.4, *Coastal Habitat and Fauna*, as the area within a 1.0-mile buffer of the Onshore Project area and focuses on the impacts on terrestrial flora and fauna, including noise, land disturbance, presence of structures, and traffic. The effects of accidental releases on nearshore waters are described in Sections 3.5.2, *Benthic Resources*; 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*; 3.5.6, *Marine Mammals*; 3.5.7, *Sea Turtles*; and 3.4.2, *Water Quality*. This is consistent with other BOEM offshore wind EISs, such as Empire Wind.
BOEM-2023-0011-0185-0055	EIS Section: 3.5.4 PDF Page: Global Comment: Under the Noise IPF for each alternative please provide more information on what type of noise is anticipated from what activities and when these noise activities are expected to occur.	Section 3.5.4.5 describes construction and O&M noise impacts on coastal habitat and fauna, including noises from construction of converter stations/substations and cable-laying routes. Because the onshore noise impacts are temporary and would be consistent with typical construction noise in the geographic analysis area, BOEM anticipates negligible impacts and believes the information provide is adequate to characterize these onshore impacts.
BOEM-2023-0011-0185-0056	EIS Section: 3.5.4 PDF Page: Global Comment: Please present full descriptions of the BMPs alluded to. For example under Impacts of Alternative B Traffic it states "Mayflower Wind would develop a Vegetation Management Plan and implement best management practices to minimize potential impacts on vegetation communities during construction." The	The analysis in Section 3.5.4 summarizes some of the applicant-committed measures that would avoid and minimize impacts and refers the reader to Appendix G of the EIS and the COP Volume II for more details. Listing all the measures proposed by the applicant in each Chapter 3 resource section would add unnecessary page length when

Comment No.	Comment	Response
	FEIS should outline the BMPs that are committed to by BOEM and the developer.	the measures are readily available in Appendix G, *Mitigation and Monitoring*.
BOEM-2023-0011-0185-0057	EIS Section: 3.5.4 PDF Page: Global Comment: Cumulative impacts analyses for all alternatives should also consider impacts and damages to marine habitats and fauna within 3 nm of shore and should not be limited to impacts to terrestrial habitats. This includes any cable emplacement dredging HDD etc. Any impact level determinations should be modified to include these habitats if necessary.	The coastal habitat and fauna geographic area analysis is defined in the Draft EIS in Section 3.5.4, *Coastal Habitat and Fauna* (Figure 3.5.4-1). This section covers the area within a 1.0-mile buffer of the Onshore Project area. The environment and environmental consequences of Project activities that are in the geographic analysis area and extend into state waters are presented in Sections 3.5.2, *Benthic Resources*; 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*; 3.5.6, *Marine Mammals*; 3.5.7, *Sea Turtles*; and 3.4.2, *Water Quality*.
BOEM-2023-0011-0185-0058	EIS Section: 3.5.4.1 PDF Page: 242 Comment: Per the BOEM description coastal habitat includes flora and fauna within state waters (which extend 3 nm [5.6 kilometers] from the shoreline). However the current Description of Affected Environment section is lacking identification and/or description of aquatic or marine coastal habitats within this area (e.g. SAV) and the description is currently limited to primarily onshore and terrestrial resources. Please include all coastal habitats that occur within this defined area.	See response to comment BOEM-2023-0011-0185-0057.
BOEM-2023-0011-0185-0059	EIS Section: 3.5.4.5 PDF Page: 255 Comment: Land Disturbance IPF: Please provide more specific information on planned HDD operations. Where they will be occurring how much habitat will be impacted at what depths will they occur etc. Additionally provide further analysis on how these operations may impact marine coastal flora and fauna within 3 nm of shore.	Section 3.5.4.5, *Land Disturbance*, of the EIS describes the landfall and horizontal directional drilling (HDD) locations and impacts and refers to the COP for additional detailed mapping. EIS Chapter 2, *Alternatives,* includes maps showing the landfall locations. For marine coastal flora and fauna within 3 nautical miles (nm) of shore, please see response to comment BOEM-2023-0011-0185-0057.
BOEM-2023-0011-0185-0060	EIS Section: 3.5.4.5 PDF Page: 255 Comment: Land Disturbance IPF: the DEIS states "To the greatest extent practicable construction would take place away from significant fish and wildlife habitats and during times when highly sensitive species are not likely to be present." Please	The text referenced by the comment is an applicant-committed measure from the COP. The measure does not include details but is rather a general commitment to minimize effects on fish and wildlife habitat, which would include adhering to any state-required timing or avoidance

Comment No.	Comment	Response
	provide more information on these timelines and identify the highly sensitive species to which you are referring. 3.5.4.5	buffers and other requirements for ESA-listed species identified through Section 7 consultation with the U.S. Fish and Wildlife Service (USFWS).
BOEM-2023-0011-0185-0061	EIS Section: 255 Comment: Traffic IPF: the DEIS states "To the extent practicable construction activities would take place outside of periods when highly sensitive species are likely to be present." Please provide more specific information on these timelines and identify highly sensitive species that may be impacted.	Please refer to response to comment BOEM-2023-0011-0185-0060.
BOEM-2023-0011-0185-0062	EIS Section: 3.5.4.6 PDF Page: 257 Comment: In this section the DEIS states that "The types of impacts under Alternative C-1 and Alternative C-2 would be similar to those described for the Proposed Action but slightly greater due to the larger area of land disturbance in coastal habitats" and that "In context of reasonably foreseeable environmental trends the incremental impacts contributed by Alternative C to the cumulative impacts on coastal habitat and fauna would be slightly greater than the Proposed Action..." When determining impacts it is important to consider not just total area impacted but the rarity sensitivity and importance of the habitats impacted. In this case although Alternative C does impact more area than the proposed alternative this onshore area is previously disturbed existing road ROWs which do not provide the same important habitats for managed species as does the habitat within the Sakonnet River which would be fully avoided by this alternative. As such please ensure that language and impact evaluations accurately represent the cumulative impacts not just the total area.	The impact described in Section 3.5.4.6 is on coastal habitat and fauna in the geographic analysis area, which includes the area within a 1.0-mile buffer of the Onshore Project area. Therefore, the analysis focuses on relative impacts on terrestrial resources. The beneficial impacts of avoiding environmental resources within the Sakonnet River are discussed in other resource sections, including Sections 3.5.2, *Benthic Resources*, and 3.5.5, *Finfish, Invertebrates, and Essential Fish Habitat*.
BOEM-2023-0011-0185-0063	EIS Section: 3.5.4.7 PDF Page: 259 Comment: Please provide the same level of analysis for all alternatives including separate evaluations for each potential IPF. There is significant information lacking for Alternatives D E and F on Coastal Habitats and Fauna which are currently grouped together. In order to properly evaluate impacts to NOAA trust	As described in Section 3.5.4.7, because Alternatives D, E, and F would involve modifications only to offshore components, impacts on coastal habitat and fauna from Alternatives D, E, and F would be the same as those under the Proposed Action. In-depth evaluations of NOAA trust resources for Alternatives D, E, and F are presented in Draft EIS Sections 3.5.2, *Benthic Resources*; 3.5.5, *Finfish, Invertebrates, and*

Comment No.	Comment	Response
	resources complete robust evaluations of potential impacts for are necessary for all alternatives.	*Essential Fish Habitat*; 3.5.6, *Marine Mammals*; 3.5.7, *Sea Turtles*; and 3.4.2, *Water Quality.*
BOEM-2023-0011-0185-0064	EIS Section: 3.5.4.8 PDF Page: 259 Comment: Please provide rationale for why there are currently no mitigation or minimization measures proposed for this section. Various adverse impacts on coastal habitats and fauna are presented so NMFS recommends adopting BMPs and mitigation measures that can minimize these impacts where possible.	Impacts on coastal habitat and fauna are identified as minor for all resources and it was therefore determined that no mitigation was warranted. Additionally, coastal habitat and fauna are outside of BOEM's jurisdiction; any state requirements for wildlife mitigation would be followed.
BOEM-2023-0011-0185-0065	Section 3.5.5: Finfish Invertebrates and Essential Fish HabitatEIS Section: 3.5.5 PDF Page: Global Comment: NMFS biological opinions are not primary literature and should not be used as citations for project impacts. All such references should be replaced by primary literature.	NMFS (2019) and NMFS (2021d) biological opinion citations have been removed and/or replaced with primary literature throughout the Section 3.5.5*, Finfish, Invertebrates, and Essential Fish Habitat*.
BOEM-2023-0011-0185-0066	EIS Section: 3.5.5 PDF Page: Global Comment: Please provide a clear impact determination (including duration and severity) for each IPF as defined by Table 3.5.5-2. Please provide a distinct subheading for each IPF accompanied by its own complete analysis rather than lumping several IPFs into one paragraph. Robust evaluations and consideration of IPFs should be provided for all alternatives not just for the Proposed Action. Additionally ensure that impact determinations for each IPF are consistent with the best available science and consistent throughout the document and match the information provided within the analyses. Again refer back to impact determination tables at the beginning of the section for a clear definition of each impact level. Similarly, please ensure the language within the evaluations and conclusions are not being used to either dilute alternatives under consideration or bolster the Proposed Action alternative (Alternative B). For example, it is stated that Alternative C would "avoid EFH and HAPC reduce the total export cable route by 9 miles and reduce the total offshore export cable route by 12 miles." However, it is later stated that the measures under this alternative "would not have measurably different impacts on finfish invertebrates	BOEM has reviewed each Chapter 3 resource section and included an impact determination for each IPF if one was not already provided in the Draft EIS and ensured the impact determinations are appropriate based on the impact level definitions and the information contained in the analysis. Under the analysis of Alternatives C, D, E, and F, separate IPF headings were not considered necessary if the analysis could be more concisely described without the headings or the IPF being discussed was apparent from the context. This approach is consistent with other BOEM offshore wind EISs. Regarding the analysis of Alternative C, BOEM has updated the analysis with additional desktop studies performed by SouthCoast Wind, which include a benthic desktop study and a geohazard study. The language regarding difference in impacts not being measurable has been removed; however, the overall impact conclusion has not changed as Alternative C would only result in a change to a small portion of the overall Project. To further describe the difference in impacts among the alternatives, BOEM has added Section 3.5.5.10, *Comparison of Alternatives*, to the Final EIS.

Comment No.	Comment	Response
	and EFH than the Proposed Action" and that "In the context of reasonably foreseeable environmental trends cumulative impacts of Alternative C would be similar to those described under the Proposed Action." These statements are contradictory. NFMS disagrees that there would not be measurable differences. The quantitative number of miles of benthic habitat (including HAPC and EFH) spared by Alternative C is indeed a measurably different (and reduced) impact as well as the importance of locations being avoided. Please ensure evaluations are fair and indicative of all information presented and avoid language that inaccurately equalizes impacts the Proposed Alternative to other alternatives if this comparison is unsupported.	
BOEM-2023-0011-0185-0067	EIS Section: 3.5.5 PDF Page: Global Comment: Any mitigation measures that are mentioned within the evaluation of alternatives should be clearly explained and committed to during construction operation and decommissioning. Simply stating that mitigation or minimization measures "may" be put into place should not be considered within impacts evaluations. For example under Accidental Releases it is stated that "any accidental releases are expected to be localized and subject to mitigation to minimize environmental impacts." However no description or requirement of these mitigation measures is provided. Similarly a following sentence states "therefore with mitigation measures in place the total volume of contaminants and trash debrs from accidental releases would be negligible...". Lower or reduced impacts determinations cannot be justified by a mitigation measure if it is not clear what the mitigation measure fully entails or whether the developer is committed to implementing the measure. Please ensure all mitigation measures are fully explained and do not discuss actions or mitigations that will not be required of the developer.	Applicant-committed mitigation measures proposed by SouthCoast Wind in its COP or other applications (e.g., ITR application, National Pollutant Discharge Elimination System [NPDES] permit application) are considered part of the Proposed Action and are analyzed as such in the text. BOEM and other agency proposed mitigation measures are not considered part of the Proposed Action and are separately described in Section 3.5.5.11, along with a discussion of the effect of each measure. The two text excerpts referenced in the comment about accidental releases are under the analysis of the No Action Alternative and are not specific to the Proposed Action. The specific mitigation measures proposed for all ongoing or planned offshore wind and non-offshore wind project are not fully known, but BOEM anticipates compliance with regulations and industry standards would minimize the potential for and effects from accidental releases, as is stated in the text.
BOEM-2023-0011-0185-0068	EIS Section: 3.5.5 PDF Page: Global Comment: Based on our review of the DEIS it does not appear that all necessary data	Text in Section 3.5.5.5 subsection on Noise: G&G survey (HRG Surveys and Geotechnical Drilling Activities) has been revised

Comment No.	Comment	Response
	has been collected to fully evaluate effects of the proposed action and compare those effects with the proposed alternatives. It is unclear when these outstanding surveys will be completed and how BOEM will use that information to inform their decision-making process. For example site assessment surveys have not yet been completed for the alternative offshore export cable routes. Additionally under Cable Emplacement and Maintenance in Section 3.5.5.3 it is stated that "Contractors and engineers for Mayflower Wind would perform additional surveys and evaluations of geological conditions of the surface and shallow subsurface layers prior to developing the precise route." On page 3.5.5-50 under Noise it states "The geotechnical surveys would take place prior to construction... The HRG and geotechnical surveys would help identify sensitive habitats (e.g. shellfish SAV beds) and allow these areas to be avoided to the extent practicable for siting of the WTGs OSPs and cable routes." Surveys necessary to identify sensitive habitats should be done prior to the DEIS. It is also unclear if this project has completed geotechnical cores to understand the feasibility of construction in the lease area. This information should be completed earlier in the process and should inform the analysis in the EIS.	to indicate that geotechnical surveys have been completed between 2019 and 2022 including the identification of sensitive habitats. However, while reconnaissance high-resolution geophysical (HRG) surveys have been conducted, HRG surveys would be conducted intermittently during construction to identify any seabed debris and provide construction support. HRG surveys would also be carried out on a routine basis during the operations phase (3 years following the first 2 years of construction). For the geotechnical surveys already conducted, geotechnical boreholes were taken across the Lease Area in 2019 and 2020. A vibracoring campaign was conducted in 2020 to gain an understanding of site conditions along the Falmouth ECC. Additional geotechnical surveys of the shallow sections on the Falmouth ECC, the full Brayton Point ECC, and the Lease Area were completed in 2021. Text regarding additional surveys for cable emplacement has been updated in Section 3.5.5.5, *Cable emplacement and maintenance*, with updated site-specific information on cable routing and impacts in the Brayton Point and Falmouth ECCs. The shallow nearshore survey was conducted to map SAV and show that horizontal directional drilling (HDD) exit pits would occur outside of the furthest extent of eelgrass beds and not directly impacted. Further information of SAV impacts are outlined in the Final EIS, Section 3.5.2, *Benthic Resources*, section and COP Appendix K. For Alternative C, SouthCoast Wind, at BOEM's request, commissioned two desktop studies using existing site-specific and regional data to inform BOEM's assessment of the Alternative C cable routes: *SouthCoast Wind BOEM Alternative C Geohazard Desktop Study* (TetraTech 2023) and *SouthCoast Wind BOEM Alternative C-1 Benthic Desktop Study* (INSPIRE 2023). The findings from these desktop studies have been incorporated into the Final EIS (principally Section 3.5.2 and Section 3.5.5) and support BOEM's analysis of the cable routes.

Comment No.	Comment	Response
		SouthCoast Wind completed geotechnical surveys for the full Lease Area build out in 2023. Geotechnical data indicates that seabed conditions support installation of the foundation types and sizes in the PDE.
BOEM-2023-0011-0185-0069	EIS Section: 3.5.5.1 PDF Page: 260 Comment: In the 2nd sentence add "anadromous" in the parenthetical list of life history/habitat groupings. 3.5.5.1 PDF Page: 262 Comment: American eels are very common in Delaware River/Bay and Chesapeake Bay not just New England. Please clarify.	"Anadromous" has been added to the parenthetical list of life history/habitat groupings in Section 3.5.5.1. The sentence on American eel distribution has been edited to "coastal river systems along the east coast of North America."
BOEM-2023-0011-0185-0070	EIS Section: 3.5.5.1 3.5.5.3 and 3.5.5.5 PDF Page: 264 293 and 312 Comment: Given that project vessels will transit specific waterways that Atlantic sturgeon inhabit (i.e. Port of Virginia/James River) risk of vessel strike may not be extremely unlikely to occur. This text needs to be revised in the EIS to accurately assess the risk of project vessel traffic on listed fish. Risk of vessel strike to Atlantic sturgeon in the James River is of particular concern particularly during the time of year when spawning adults are entering the river. We recommend that BOEM more comprehensively address the risk of vessel strike in this portion of the action area.	The potential for vessel strikes to Atlantic sturgeon was revised to extremely unlikely to occur in the majority of the Project area. Following the release of the Draft EIS, SouthCoast Wind removed the Port of Virginia as a potential marshalling port from its COP. Therefore, the Final EIS has been revised to remove the discussion of potential effects associated with sturgeon presence in the James River.
BOEM-2023-0011-0185-0071	EIS Section: 3.5.5.1 PDF Page: 270 Comment: In Table 3.5.5.1 please ensure to differentiate the status harvest trend stock trend and biomass of individual stocks (sub- populations) of each species for which EFH exists within the project area. Specifically more detailed information is needed for separate stocks of cod yellowtail flounder haddock silver hake red hake and monkfish. Stock status and associated stock/fishery trends can differ within a species. For example cod are currently managed as 2 stocks (Georges Bank and Gulf of Maine) but that may increase to up to 5 stocks based on information provided in McBride and Smedbol 2022 (https://repository.library.noaa.gov/view/noaa/48082) (Hyperlink: https://repository.library.noaa.gov/view/noaa/48082). Stock status and resource trends for individual stocks can be found	More information on the different stocks of Atlantic cod, yellowtail flounder, haddock, silver hake, red hake, and monkfish has been incorporated into Table 3.5.5-1 using data from NOAA Fisheries Stock SMART (NMFS 2024a).

Comment No.	Comment	Response
	using NOAA Fisheries' Stock SMART tool (https://apps-st.fisheries.noaa.gov/stocksmart?app=homepage) the same reference listed in the DEIS.	
BOEM-2023-0011-0185-0072	EIS Section: 3.5.5.1 PDF Page: 278 Comment: Essential Fish Habitat: This paragraph states "Evidence of cod spawning has been observed in an area known as Cox ledge which lies on the northwest corner of the Massachusetts and Rhode Island wind energy areas. Variations of this proposal would designate the area around Cox Ledge and parts of the wind energy area as an HAPC for cod spawning but would not overlap the Project area. An alternative variation of this proposal would extend the HAPC beyond Cox Ledge to cover all complex habitat in the southern New England wind energy area with a 10-km buffer around the wind energy area." This statement is incorrect and should be revised in the FEIS. The project overlaps with HAPC for summer flounder and juvenile cod and the recently approved HAPC for spawning cod and complex habitats. The NEFMC approved an HAPC that is focused on protecting two elements - 1) complex habitats; and 2) cod spawning activity - from the anthropogenic pressure and development in Southern New England specifically offshore wind development. To be considered for an HAPC designation the 2002 EFH regulations (50 CFR Part 600.815(a)(8)(i)-(iv)) requires one or more of the following four criteria to be met: 1) importance of historic or current ecological function for managed species; 2) sensitivity to anthropogenic stresses; 3) extent of current or future development stresses; and/or 4) rarity of the habitat type. As described in detail in the NEFMC's Draft Submission to us dated August 22 2022 the Council's approved HAPC meets all four of these criteria for the designation of an HAPC for Atlantic cod spawning activity and three of the criteria for the designation of an HAPC for complex habitat. The Council's approved HAPC applies to any area where cod spawning activity is identified (based upon specified criteria) regardless of the habitat type where spawning occurs. This is particularly	Final EIS Section 3.5.5.1 has been revised to include the Southern New England habitat area of particular concern (HAPC) specific to cod spawning in addition to the summer flounder HAPC and juvenile Atlantic cod HAPC. The paragraph discussing the Southern New England HAPC has been revised and the proposed alternatives as presented in the New England Fishery Management Council (NEFMC) (2023) document have been included. Reference to the Atlantic cod spawning dynamics study by Van Hoeck et al. (2023) has also been added.

Comment No.	Comment	Response
	important to clarify as cod spawn over a variety of habitat types and use different habitat types within aggregation areas. These HAPCs should be accurately described and impacts evaluated in the EIS. Additionally it should be noted that data collected in adjacent lease areas and recently presented at the NYSERDA SOS workshop (Van Parijs S. Dean M. McGuire C. Cadrin S. and Frey A. 2022 July 26-28. Preconstruction evaluation of Atlantic cod spawning in Southern New England offshore wind areas [Conference presentation]. NYSERDA State of the Science Workshop Tarrytown NY United States) indicated that spawning condition cod were captured in lease areas immediately adjacent to the project area during pre-construction fisheries surveys completed for other projects. The presence of ripe and ripe & running cod in the trawl indicates that spawning occurs within the immediate vicinity of captured spawning condition cod; however surveys to detect the location of spawning aggregations have not yet been conducted in this area. While surveys have not yet been conducted in this project area there is data to suggest spawning is occurring in adjacent areas and outside Cox Ledge.	
BOEM-2023-0011-0185-0073	EIS Section: 3.5.5.3 PDF Page: 280 Comment: The citation provided (NOAA 2019) does not appear to support the conclusion about which gear types are the major contributors of the identified bycatch.	The NOAA (2019) in-text citation has been removed and the sentence has been simplified to only include commonly impacted species from bycatch. The NOAA (2019) reference has been deleted from Appendix J as a global edit removing biological opinion references used as primary literature.
BOEM-2023-0011-0185-0074	EIS Section: 3.5.5.3 PDF Page: 282 Comment: Impacts to pelagic eggs should be added under adverse effects of accidental releases not just larvae.	Pelagic eggs have been added to the sensitive life stages that could experience potential lethal or sublethal effects from accidental releases.
BOEM-2023-0011-0185-0075	EIS Section: 3.5.5.3 PDF Page: 284 Comment: Clarify what species the distances of EMF detection are based on. Some elasmobranchs demonstrate sensitivity down to 0.5– 1000 mVm-1 (Kalmijn 1982; Kilfoyle et al 2018); EMFs of 0.5–100mVm-1 may attract some species whereas EMFs over 100 mVm-1 are generally avoided (Kalmijn 1982; Tricas and Gill	The statement, “an EMF that could elicit a behavioral response in an organism would likely extend less than 50 feet (15.2 meters) from each cable”, has been removed and replaced with text noting that the area around submarine power cables with elevated EMF levels extends less than approximately 33 feet (10 meters) around each cable.

	2011). Good discussion in Horodysky et al 2022. 3.5.5.3 and 3.5.5.5	
BOEM-2023-0011-0185-0076	EIS Section: 284 and PDF Page: 302 Comment: Undersea cables have been shown to affect migratory routes of salmonids (Wyman et al 2018) and swimming rates of telemetered eels (Westerberg and Lagenfelt 2008). Overhead cables affect migratory behavior in Atlantic salmon and Russian sturgeon (Poddubny et al. 1979). Please consider incorporating these sources.	Neither Westerberg and Lagenfelt (2008) nor Wyman et al. (2018) suggest deleterious effects to the migration of the studied organisms. Westerberg and Lagenfelt (2008) ultimately conclude that the approximately 40 minute slow-down in the 7,000 kilometers migration of European eels was not significant from a fitness standpoint for European eels. Further, the cable studied was unburied and was AC. The cable under study in Wyman et al. (2018) was much more applicable to the cable used for Southcoast Wind, with an achieved burial depth of ~6 feet, and the cable was DC, however with less load than the proposed cables for Southcoast Wind 200 kilovolts (kv) versus 320 kv. While cables did appear to affect juvenile salmonid migration, these effects were minor and did not greatly reduce the ability of Juvenile salmonds to migrate along the cable route out into the Pacific Ocean. Other environmental factors further confound the ability to accurately predict the impact the cable had on migrating smolt, such as discharge, temperature, depth, and release location of tagged salmonids. Salmonids showed an attraction to the cable in all array locations, but this did not lead to an overall decrease in the ability of salmonids to migrate to the open ocean, compared to the two previous years when the cable was inactive. Poddubny et al. (1979) is about an overhead transmission line, which is not proposed for the SouthCoast Wind Project. The Wyman et al. (2018) source was added to Section 3.5.5, *Finfish, Invertebrates and Essential Fish Habitat*.
BOEM-2023-0011-0185-0077	EIS Section: 3.5.5.3 PDF Page: 286 Comment: Artificial light at night (ALAN) can alter migratory patterns and even food webs via point source (Cooke et al 2017) or general sky illumination (see Mazur and Beauchamp 2006). But shadows of overwater structures can also affect adult migration larval	Text added to Section 3.5.5.5 to incorporate additional information on impacts from artificial light, including impacts on larval and zooplankton diel migratory patterns. The overall impact conclusion is supported by the best available literature and is unchanged.

Comment No.	Comment	Response
	settlement feeding predation risk etc. (Ono and Simenstad 2014; Sabal et al 2021; O'Connor et al 2019). It doesn't take much light for hormonal changes (Kupprat et al 2020). And the effects can be seen across multiple trophic levels (Bolton et al 2017). Consider incorporating these references.	As stated in Section 3.5.5.5, the light from WTGs and OSPs would be intermittent flashes of red hues, and marine navigational lights, which are characterized by intermittent flashes of yellow hues, neither of which present a continuous light source. Additionally, red and yellow lights are among the shallowest penetrating lights on the ultraviolet (UV) spectrum due to light attenuation properties in seawater, meaning that the impact of these intermittent light sources would have very localized effects. After reviewing the cited literature in this response and further analysis, the cited impacts do not all necessarily apply. For example, Mazur and Beauchamp (2006) is a model of projected increased predation rates and foraging success of trout experiencing constant light pollution, which is not anticipated for the Proposed Action. Ono and Simenstad (2014), argue shading of structures effects on juvenile salmon; shading from a dock and a WTG are not equivalent. The findings in Kuppart et al. (2020) appear species dependent as Newman et al. (2015) and Szekeres et al. (2017) found conflicting results (no impact on stress levels in salmon; no behavioral impacts on bonefish). Largely, these studies revolve around coastal or inland species which would experience much more persistent and intense forms of artificial light at night than at offshore wind farms. Lastly, the description of artificial light impacts are consistent with other BOEM offshore wind EISs, including Ocean Wind 1 and Empire Wind EISs.
BOEM-2023-0011-0185-0078	EIS Section: 3.5.5.3 PDF Page: 289 Comment: Pile driving effects on flatfish and skates/rays is unknown but can be hypothesized as more extreme (they directly contact the benthos over a large surface area potentially transmitting shock to internal organs) unless they evacuate. Studies in Europe and NE USA show low probability of harm if pile driving is conducted when flatfish are at low abundance.	Flatfish including Winter Flounder and other elasmobranchs (e.g., rays, skates, and sharks) do not have swim bladders. As such, they are least susceptible to sound. COP Appendix N provides sound levels that would provide mortality, injury or avoidance behaviors for fishes (flatfishes and skates/rays) without swim bladders. The Underwater Acoustic Assessment (COP Appendix U2) provides the results of sound modeling associated with the foundation pile driving. Mortality or injury due to sound exposure would only occur in the

Comment No.	Comment	Response
		immediate vicinity of the pile driving. Behavioral disturbances may occur up to 10.6 miles (17 kilometers) away, depending on the jacket foundation/monopile size, hammer energy, and fish size (see Section 3.7 of COP Appendix U2 for detailed tables).
BOEM-2023-0011-0185-0079	EIS Section: 3.5.5.3 PDF Page: 291 Comment: Please provide a source for the information presented when describing noise impacts of HRG on finfish and invertebrates.	The citation in question (BOEM 2021) has been added to Section 3.5.5.3. Sound impacts on finfish and invertebrates, and avoidance behaviors are now also detailed in COP Appendices N and U2.
BOEM-2023-0011-0185-0080	EIS Section: 3.5.5.3 PDF Page: 294 Comment: Recommend reviewing Christiansen et al (2022) as this research suggests the potential for large-scale hydrodynamic effects.	The *presence of structures* IPF in Section 3.5.5.3 has been expanded with added discussion on hydrodynamic effects which also incorporates Christiansen et al. (2022) and other similar studies. BOEM has also partnered with NASEM for an independent peer review of potential hydrodynamic impacts of offshore wind facilities in the Nantucket Shoals region. Results of this study are reported in the *presence of structures* IPF in Section 3.5.5.5.
BOEM-2023-0011-0185-0081	EIS Section: 3.5.5.5 PDF Page: 298 Comment: Anchoring IPF: please include a discussion of spud can impacts to EFH unless listed elsewhere or not intended to be an anticipated impact. Use of spud cans for construction vessels could result in long-term impacts to EFH including the need for backfill and associated potential habitat conversion. If spud cans will be used for this project the impacts should be included in the EIS.	A reference to spud can impacts has been included in the *anchoring* IPF in Section 3.5.5.5. Spud can impacts are also discussed in the COP Volume 2, Section 6.6.2.2.2, and are incorporated into the overall acreage of *anchoring* IPFs in Section 3.4.1.1 of the COP Volume 1.
BOEM-2023-0011-0185-0082	EIS Section: 3.5.5.5 PDF Page: 299 Comment: Discharges/Intakes - Please provide more information on discharge and intake specifics of the project including where the outflow and inflow pipes will be located and at what depths.	Additional information has been added regarding the intake and discharge specifics of the converter station OSP cooling water intake system including the location of intake and discharge pipes relative to the converter station OSP design and the potential depths of seawater withdrawal in Section 3.5.5.5. Indicative geographic location of one of the converter station OSP is shown in Appendix B, Figure B-2.

Comment No.	Comment	Response
BOEM-2023-0011-0185-0083	EIS Section: 3.5.5.5 PDF Page: 299 Comment: Under discharges/intakes please differentiate hake species if possible and note that substantial annual removals of eggs and larvae of stocks in poor condition such as white hake Atlantic herring and Southern New England red hake could have long- term impacts to the long-term sustainability of the species and associated fishery. This should be noted here and in Section 3.6.1 of the DEIS (entrainment estimates were not discussed in this section or the potential impacts to individual species or fisheries).	"Hakes" referred to the unidentified hake species in data. These organisms were identified down to family or genus, so this is a catch all identification for potentially all species found in the area (red, white, and silver). The limitations of larval entrainment estimates associated with SouthCoast Wind's proposed HVDC converter OSP is described in a footnote in Section 3.5.5.5. SouthCoast Wind's NPDES permit application notes that fish larvae with the most relatively abundant species identified within 10 miles (16 kilometers) of the proposed intake location from 2010 through 2019 were unidentified hakes, summer flounder, and silver hake (*Merluccius bilinearis*).
BOEM-2023-0011-0185-0084	3.5.5.5 PDF Page: 300 Comment: (1) Clarify if SouthCoast Wind is proposing ventless trap surveys as part of their fisheries monitoring surveys. (2) Any capture/collection of listed species is generally not considered safe some methods/measures may reduce risk such as shorter tow times and handling times. However the text does not state what the proposed tow times or handling measures are. The text about trawl survey impacts on listed fish species should be revised to include relevant information about the survey and to accurately assess the risk and impact of the fisheries resource surveys. Additionally any analysis of impacts of listed fish should be moved to the Alternative B – Proposed Action on ESA-Listed Species subsection.	The *gear utilization* IPF in Section 3.5.5.5 has been updated to include details on the proposed fisheries and benthic habitat monitoring surveys that would be conducted in the Project area. Survey types include trawl, trap, camera, and acoustic surveys for fisheries monitoring, and remotely operated vessel (ROV) stereo-camera, sediment grab sampling, and SPI/PV for benthic monitoring. Details provided for the demersal otter trawl survey also include tow speed (3.0 knots) and tow time (20 minutes). An analysis of fisheries resource survey impacts on ESA-listed fish species has been added to the *Impacts of Alternative B – Proposed Action on ESA-Listed Species* subsection of Section 3.5.5.5.
BOEM-2023-0011-0185-0085	EIS Section: 3.5.5.5 PDF Page: 301 Comment: EMF IPF: This IPF should contain a discussion about the differences between direct current and alternating current relative to EMF. This is especially pertinent as an HVDC OSP is proposed.	Text has been added to Section 3.5.5.5 discussing the differences in EMFs produced by alternating current (AC) and direct current (DC) cables.
BOEM-2023-0011-0185-0086	EIS Section: 3.5.5.5 PDF Page: 301-302 Comment: EMF IPF: Saying that there is a lack of evidence for detrimental population-level effects suggests that such evidence has been sought and not found. In actuality there have been primarily lab based studies in controlled settings. However impacts on	The statement on population-level detrimental impacts has been removed and replaced with an evidence-based statement regarding the lack of EMF effects on the population health of some fish and invertebrate species. Results from additional EMF-effect studies by Hutchison et al.

Comment No.	Comment	Response
	larval stages suggests the potential for effects that are important to populations.	(2018) and Klimley et al. (2017) are provided in the preceding text.
BOEM-2023-0011-0185-0087	EIS Section: 3.5.5.5 PDF Page: 302 Comment: EMF IPF: The conclusion for EMF is that “BOEM expects localized and long-term though not measurable impacts on finfish invertebrates and EFH from EMFs from the Proposed Action.” However above there are citations for important effects on larval haddock and crustaceans (e.g. Cresci et al. 2022 and Harsangyi et al. 2022). Please reconcile these pieces of text.	The conclusions provided for EMF impacts in Section 3.5.5.5 have been revised to reflect findings of the studies referenced in this section.
BOEM-2023-0011-0185-0088	EIS Section: 3.5.5.5 PDF Page: 302 Comment: Lighting IPF: There is a lot of literature on how fish interact with artificial light sources. Please review this literature and incorporate it into the analysis. In particular search term ALAN (Artificial Light at Night).	The lighting subsection in Section 3.5.5.5 has been expanded to include more information on the effects of artificial light on finfish and invertebrates.
BOEM-2023-0011-0185-0089	EIS Section: 3.5.5.5 PDF Page: 302 Comment: Most NE region managed marine fishes do not see red (lack red photopigments); striped bass are a clear exception that does respond visually to red wavelengths (Horodysky et al 2010). Most managed NE region marine fishes that have been studied see yellow wavelengths extremely well (Horodysky et al 2008 2010 2013). Flash rates < 60 Hz will be seen by most species as individual flashes which could be attractive or distractive (Horodysky et al 2022). But lighting also creates shadows which may serve as movement barriers or obstacles for juvenile fishes (Ono and Simenstad 2014; Sabal et al 2021; O'Connor et al 2019). Consider incorporating this information and references into the analysis in the FEIS.	Text added to Section 3.5.5.5 to incorporate additional information on impacts from artificial light, including impacts on larval and zooplankton diel migratory patterns. The overall impact conclusion is supported by the best available literature and is unchanged. Please refer to response to comment BOEM-2023-0011-0185-0077 for additional information.
BOEM-2023-0011-0185-0090	EIS Section: 3.5.5.5 PDF Page: 303 Comment: Under cable emplacement and maintenance please provide an estimate of the scale location and timing of potential seabed preparation activities including how any boulders would be deposited and where. If such information is not currently available at this time please note that and caution that the full impacts cannot be accurately estimated until such	More detail has been added in the discussion of impacts from cable emplacement and maintenance in Section 3.5.5.5 including the scale and location of potential seabed preparation activities (boulder relocation; dredging; vessel anchoring), associated impacts to habitats, finfish, invertebrates, and EFH, and mitigation measures (micro-routing of cables). Additional information on impacts from

Comment No.	Comment	Response
	information becomes available. This information is necessary to fully evaluate the impacts of cable emplacement activities on EFH and marine species as the location scale duration and seasonality of such activities substantially affect the resulting impacts. For example the section suggests for both impacts would be negligible but that depends on where the entrainment occurs relative to spawning sites and whether such activities occur during spawning season for species in the affected area. Further text notes habitat loss and conversion yet still concludes that impacts are temporary and short-term which is incorrect without specifying how much habitat would be converted the type of habitats affected and where such impacts would occur. Finally please note any mitigation measures that would be employed to reduce impacts from cable emplacement.	cable installation methods has also been added along with associated impacts. More specific details on impacts on EFH are addressed in the SouthCoast Wind Project EFH Assessment.
BOEM-2023-0011-0185-0091	EIS Section: 3.5.5.5 PDF Page: 304-309 Comment: Noise IPF: Please clarify what the overall conclusion for the impact of noise is. This section ends with a conclusion regarding G&G surveys rather than noise overall.	The concluding sentence in the noise impacts under Section 3.5.5.5 has been revised to reflect the overall noise impact of all project activities that are expected to generate noise.
BOEM-2023-0011-0185-0092	EIS Section: 3.5.5.5 PDF Page: 304-309 Comment: Noise IPF: The analysis of noise lacks a discussion substrate vibration effects on early life stages. Also missing is a discussion of how noise interacts with behavior and communication (e.g. de Jong et al. 2020 https://doi.org/10.1007/s11160-020-09598-9 (Hyperlink: https://doi.org/10.1007/s11160-020-09598-9); Siddagangaiah et al. 2021 doi: 10.1002/rse2.231 (Hyperlink: https://zslpublications.onlinelibrary.wiley.com/doi/10.1002/rse2.231); Stanley et al. 2020 doi.org/10.1242/jeb.219683) (Hyperlink: https://journals.biologists.com/jeb/article/223/13/jeb219683/222906/Ontogenetic-variation-in-the-auditory-sensitivity). The discussion on particle motion should additionally include more recent work by Sigray et al. 2022 (doi.org/10.1016/j.marpolbul.2022.113734) (Hyperlink: https://www.sciencedirect.com/science/article/pii/S0025326	The *noise* IPF analysis has been expanded to include discussions on potential disruptions of communication and behavior in fish and invertebrates as well as an expanded discussion on particle motion effects in invertebrates, specifically, and cephalopods.

Comment No.	Comment	Response
	X22004167?via%3Dihub); Sole et al. 2022 (doi.org/10.1016/j.envpol.2022.119853) (Hyperlink: https://www.sciencedirect.com/science/article/pii/S0269749122010673?via%3Dihub); Hawkins 2022 (doi.org/10.1121/10.0013994) (Hyperlink: https://asa.scitation.org/doi/10.1121/10.0013994).	
BOEM-2023-0011-0185-0093	EIS Section: 3.5.5.5 PDF Page: 305 Comment: Please clarify why the acoustic radial distance at Location 1 is smaller for behavioral effects at 150 dB than small fish injury at 183 dB. This seems counterintuitive when the distance is larger at Location 2.	Table 3.5.5-8 showing acoustic radial distances for fish during pile driving has been revised to reflect results from updated underwater acoustic modeling scenarios in Limpert et al. (2023). For all pile-driving scenarios, acoustic radial distances are largest for the Behavioral (all fish) category, followed by the Injury over 24hr (fish < 2 grams) category, then the Injury over 24hr (fish ≥ 2 grams) category. The smallest acoustic radial distances are in the Single Strike Injury (all fish) category for all pile driving scenarios modeled.
BOEM-2023-0011-0185-0094	EIS Section: PDF Page: 306 Comment: Clarify what "small fish" and "large fish" refer to in Table 3.5.5-5. This information should be included below the table.	Table 3.5.5-8 for fish during pile driving under various scenarios, with 10-decibel noise attenuation from a noise-abatement system) has been updated and no longer includes the terms *small fish* and *large fish*.
BOEM-2023-0011-0185-0095	EIS Section: 3.5.5.5 PDF Page: 308 Comment: Noise IPF: Mooney et al. 2020 is incorrectly cited. The information attributed to this reference was cited by Mooney et al. 2020 but was not research conducted by them.	The Mooney et al. (2020) reference in Section 3.5.5.5 has been replaced with the appropriate citation: Westerberg (1994, as cited in Mooney et al. 2020).
BOEM-2023-0011-0185-0096	EIS Section: 3.5.5.5 PDF Page: 308 Comment: Noise IPF: Please include a full description of the potential impacts from noise and vibration associated with construction and operations. Operational noise as noted for marbled rockfish could also mask acoustic communication for other species such as cod that rely upon communication for spawning. This would occur for the duration of the project and would have a lingering effect unlike temporary masking from ship noise. Pile driving noise may produce a startle or avoidance response that may interrupt social spawning for species like cod and squid that exhibit elaborate spawning behavior.	Section 3.5.5.5 has been expanded to include discussions on the effects of noise on behavior, communication, and spawning of fish and invertebrate species.

Comment No.	Comment	Response
	Vibrations within the sediment has also been shown to affect shellfish respiration and feeding as noted in our comments for previous actions. This section should note these impacts.	
BOEM-2023-0011-0185-0097	EIS Section: 3.5.5.5 PDF Page: 308 Comment: Idealized propagation distances for reproductive vocal communications of sciaenid fishes (croakers and drums) are provided in Table 4 in Horodysky et al 2008. These species can hear each other's soniferous lekking from 8-128 m away absent any background noise. Some are offshore spawners in regions sited for wind and should be included herein as Atlantic croaker (and black drum) are moving north with climate change.	A description of the impacts to soniferous fish (mainly Atlantic cod) has been added to Final EIS, Section 3.5.5.5.
BOEM-2023-0011-0185-0098	EIS Section: 3.5.5.5 PDF Page: 309 Comment: It is unclear why seasonal restrictions of UXO detonations from December through April will eliminate exposure to Atlantic sturgeon when the species is generally in the ocean at this time. Adults may spawn in rivers from the spring into summer but not all adults move into the river system at this time. This assessment of UXO impacts on listed fish species should be revised to be more comprehensive. Additionally any analysis of impacts of listed fish should be moved to the Alternative B – Proposed Action on ESA-Listed Species subsection.	If Atlantic sturgeon are present in the Project area during December through April, they would benefit from seasonal restrictions on unexploded ordnance (UXO) detonation. More detail on the UXO desktop study and potential impacts from UXO detonation has been added to Section 3.5.5.5 under the *noise* IPF.
BOEM-2023-0011-0185-0099	EIS Section: 3.5.5.5 PDF Page: 309 Comment: The DEIS does not consider impacts to reproduction/spawning activity from UXO detonation. Specifically further analysis of impacts to finfish and invertebrate species particularly those that aggregate to spawn including Atlantic cod and longfin squid should be analyzed in the FEIS.	A discussion on impacts to reproduction/spawning activity for Atlantic cod and longfin squid has been added to the noise section in Alternative B.
BOEM-2023-0011-0185-0100	EIS Section: 3.5.5.5 PDF Page: 309 Comment: Presence of Structures IPF: Please note that predator-prey interactions may change due to increases to certain structure-affiliated species which may result in positive and negative impacts to various species. For example increased structure may attract black sea bass which could prey on younger lobster resulting	Text has been added to Section 3.5.5.5 regarding changes to trophic dynamics and predator–prey interactions, with specific mention of adverse impacts on some juvenile fishes and invertebrates due to the presence of structures.

Comment No.	Comment	Response
	in positive impacts for black sea bass but negative impacts to lobsters and other prey species.	
BOEM-2023-0011-0185-0101	EIS Section: 3.5.5.5 PDF Page: 309-310 Comment: Presence of Structures IPF: Analysis of the presence of structures is insufficient. This analysis should include a discussion of FAD (fish aggregating device) effects; artificial reef effects; modification of the prey field for upper level predators the potential for structures to facilitate the establishment and range expansion of non-native species; local hydrodynamic and broad scale wind-wake effects on larval transport primary and secondary production planktonic food availability etc. Please also include relevant supporting literature to support statements made. Other than the COP there is scant literature provided grey or peer- reviewed to support any of the statements made. There is a growing body of knowledge on these topics and the majority of this information is missing from the analysis.	The presence of structures IPF analysis in Sections 3.5.5.3 and 3.5.5.5 has been revised with added discussions on artificial reef effects, fish aggregation, altered trophic dynamics, invasive-species spread, changes in primary production, effects on larval transport, and localized and broad-scale atmospheric and hydrodynamic effects. The revised text is presented along with appropriate references.
BOEM-2023-0011-0185-0102	EIS Section: 3.5.5.5 PDF Page: 310 Comment: Please note that while net primary productivity in the entire North Atlantic may not be measurably affected by the presence of structures localized primary productivity would likely be affected at measurable levels based on the text included in this section and recent literature on this topic. This could have important localized effects on marine species that rely on primary and secondary productivity. Comparing project level effect to the entire North Atlantic due to the Gulf Stream artificially dilutes the potential impacts that may occur within the project area.	The *presence of structures* IPF in Section 3.5.5.5 has been revised to acknowledge that both localized and broad scale impacts can occur as a result of atmospheric and hydrodynamic effects from the presence of WTGs, which include changes in stratification and primary productivity. Section 3.5.5.3 has also been expanded with added discussions on this topic.
BOEM-2023-0011-0185-0103	EIS Section: 3.5.5.5 PDF Page: 312 Comment: The Impacts of Alternative B – Proposed Action on ESA-Listed Species subsection only briefly assesses noise and traffic impacts on listed fish however all other IPFs assessed for finfish in the greater section should also be assessed for listed fish in the subsection. This is especially pertinent for UXOs fisheries/marine resource surveys water	Section 3.5.5.5, *Impacts of Alternative B – Proposed Action on ESA-Listed Species*, has been revised to include additional information on impacts specific to ESA-listed fish species. Text relevant to all fish species is retained in the main analysis section to avoid repetition.

Comment No.	Comment	Response
	withdrawals/impingement and benthic impacts from habitat loss dredging and cable laying - both offshore and in nearshore habitats. This information should be consistent with the BA (see comment below). Additionally mentions to listed fish are intermingled throughout the analysis of IPFs on finfish inverts and EFH - to avoid confusion all IPF impacts on listed fish should be included in the Alternative B – Proposed Action on ESA-Listed Species subsection.	
BOEM-2023-0011-0185-0104	EIS Section: 3.5.5.5 PDF Page: 312 Comment: The EIS should contain a summary of the findings in the BA. The New England Wind DEIS (and our ensuing comments) can be used as a structure to follow for integrating this information. If the BA will not be included as an appendix to the final document we encourage BOEM to make the BA publicly available on the SouthCoast webpage (not just on the ESA consultation page) so that the information can be easily referenced by the public.	Findings from the BA have been incorporated in various parts of Section 3.5.5, as well as other sections as appropriate, specifically in Section 3.5.6, *Marine Mammals*, and Section 3.5.7, *Sea Turtles*. The BA is publicly available on BOEM's website at https://www.boem.gov/renewable-energy/state-activities/nmfs-esa-consultations.
BOEM-2023-0011-0185-0105	EIS Section: 3.5.5.5 PDF Page: 312 Comment: The rationale for why Atlantic sturgeon will not suffer injury from pile driving even though the distance to injury thresholds are short is not provided in the text. The distance to LE is ~9km and it is unlikely that a sturgeon would stay within this proximity for 24 hours however Lpk is 0.14 km and thus a sturgeon could be within that range to pile driving to sustain injury. If information supports that injury will not occur the EIS should clearly state the rationale for why injury will not occur and include supporting information as part of this rationale.	Discussions on impacts of pile-driving noise on Atlantic sturgeon in the *Noise: Pile driving* and *Impacts of Alternative B – Proposed Action on ESA-Listed Species* IPF in Section 3.5.5.5 have been expanded to include a clear rationale on why injury due to pile driving noise is not expected.
BOEM-2023-0011-0185-0106	EIS Section: 3.5.5.6 PDF Page: 314 Comment: Because seabed preparation trenching and cable installation and operation would be fully avoided the Sakonnet River Alternative C would result in fewer impacts to EFH compared to the proposed action. This should be noted in this section. We disagree with BOEM's conclusion that the potential benefits of avoiding cable emplacement within the Sakonnet River	Section 3.5.5.6 has been updated to include specific details of the cable route deviations for Alternatives C-1 and C-2, including potential habitat features that may be affected by the alternative routes and the decrease in estuarine disturbance and EFH/HAPC. At BOEM's request, SouthCoast Wind commissioned a geohazard study of Alternatives C-1 and C-2 and a benthic desktop study of Alternative C-1, and

Comment No.	Comment	Response
	would not measurably reduce impacts on finfish invertebrates and EFH from both construction and operations/maintenance activities. This conclusion is also contrary to the analysis provided in the text.	the results of these analyses have been added to the Final EIS.
BOEM-2023-0011-0185-0107	EIS Section: 3.5.5.6 PDF Page: 315 Comment: The analysis in the DEIS should consider that shortnose sturgeon may occasionally be present in nearshore coastal waters such as the Sakonnet River as some individuals occasionally make coastal migrations.	Final EIS Section 3.5.5.6 has been edited to include the potential reduction of impacts on shortnose sturgeon under Alternative C. However, shortnose sturgeon are very unlikely to be in the Project area.
BOEM-2023-0011-0185-0108	EIS Section: 3.5.5.7 PDF Page: 316 Comment: Please note that Alternative D would also reduce impacts to longfin squid. Longfin squid EFH overlaps with the northern portions of the project area as noted in Guida et al 2017 (Guida V. A. Drohan H. Welch J. McHenry D. Johnson V. Kentner J. Brink D. Timmons E. Estela-Gomez. 2017. Habitat Mapping and Assessment of Northeast Wind Energy Areas. Sterling VA: US Department of the Interior Bureau of Ocean Energy Management. OCS Study BOEM 2017-088. 312 p.).	Final EIS Section 3.5.5.7 has been edited to include the Longfin inshore squid on the list of species with EFH for all life stages in the Lease Area.
BOEM-2023-0011-0185-0109	EIS Section: 3.5.5.7 PDF Page: 316 Comment: Please clarify the analysis on whether turbines would have substantial or localized effects on hydrodynamic and atmospheric effects in this section and throughout the DEIS. Reference to Christiansen et al. 2022 on page 3.5.5-55 suggests that hydrodynamic and atmospheric effects have been shown to extend for several 10s of kilometers beyond a wind farm. This contradicts discussions of such effects in other sections of the document (Executive Summary page ES-9) that suggest only localized effects in referencing Johnson et al. 2021 and North Sea studies (see page 3.4.2-13) and Li et al. 2014 (page 3.5.5-35) indicating impacts up to a kilometer from a monopile.	Revisions have been made to clarify that atmospheric and hydrodynamic effects can be both localized and broad scale as shown by the studies cited on the topic. While the Johnson et al. (2021) modeling focuses on the area near the Project area, Christiansen et al. (2022) conclude that the changes brought about by salinity and temperature from vertical structures is small compared to the long-term and interannual variability of temperature and salinity. Such changes may not be of a magnitude to be detectable because they may not differ significantly from natural variation. Despite the lack of evidence to support detectable changes in hydrodynamic patterns at such distances, the range of impacts has been updated to include ten of kilometers speculated from Christiansen et al. (2022). Revisions in Sections 3.4.2, 3.5.5.3, and 3.5.5.5 now indicate that the effect scale can range from hundreds of meters to tens of kilometers.

Comment No.	Comment	Response
BOEM-2023-0011-0185-0110	EIS Section: 3.5.5.8 PDF Page: 318 Comment: Alternative E-2 and E-3 would significantly increase the benthic disturbance and habitat loss of the proposed action. Given that Atlantic sturgeon forage benthically the impacts of this potential habitat loss should be assessed.	Text has been added in Section 3.5.5.8 stating that Alternatives E-2 and E-3 would have a larger impact on soft-bottom habitats, EFH species associated with these habitats, and ESA-listed species that forage in these habitats such as Atlantic sturgeon.
BOEM-2023-0011-0185-0111	EIS Section: 3.5.5.9 PDF Page: 318 Comment: Please be more clear about the trade-offs inherent under Alternative F in that reductions in area impacted by fewer cables may be at the cost of increased impacts to egg larvae and plankton through entrainment. Annual entrainment of millions of larvae for individual stocks of certain species in poor condition and with negative trends (cod white hake red hake and herring) due to HVDC converter stations could result in long-term impacts to those species since it will be operational during the life of the project. Additionally the trade-off of converter station operation and fewer cables will depend on the habitat type where cables are being installed. For example cables running through complex habitats are more likely to result in long-term to permanent impacts and elevated scour protection compared with cables that can be fully buried in softer sediments. These trade-off should be further discussed in the analysis.	The discussion in Section 3.5.5.9 has been expanded to include potential entrainment effects on fish with poor stock status, EMF effects from DC cables, and the reduction of impacts to complex habitats from cable emplacement activities with the reduction of the number of cables from five HVAC to three HVDC cables.
BOEM-2023-0011-0185-0112	EIS Section: 3.5.5.9 PDF Page: 319 Comment: (1) Exact terminology should be used to describe proposed project impacts suggest revising "slightly" to the extent of benthic impacts on ESA-listed fish species that will be reduced through Alternative F and what the impacts of that are. (2) An increase in HVDC converter stations poses potential risks to listed fish species and also prey of protected species those impacts should be described here.	Impacts of Alternative F on ESA-Listed Species in Section 3.5.5.9 have been revised to describe the extent of reduced benthic impact under this alternative and the potential added impact to prey of ESA-listed species due to a second converter OSP.

Comment No.	Comment	Response
BOEM-2023-0011-0185-0113	EIS Section: 3.5.5.9 PDF Page: 319 Comment: The increase in direct current cables and effects of EMF relative to alternating current cables should be discussed as part of this alternative. Fewer cables does not necessarily mean less impact the type of electrical current is also a factor. See Cresci et al. 2022.	Text has been added to section 3.5.5.9 discussing the difference in EMF amplitude produced by AC and DC cables and previous studies on DC EMF effects on fish and invertebrates.
BOEM-2023-0011-0185-0114	EIS Section: 3.5.5.9 PDF Page: 319 Comment: We recommend the lessee and BOEM consult available data and NMFS experts to determine the location of any HVDC converter station to avoid not just Nantucket Shoals but also other areas where spawning condition fish are detected and where larvae for specified stocks (see previous comments) are found. ECOmon survey data could be one source to help identify such areas. We also encourage the lessee to consult with NMFS experts about the location that would minimize impacts to such species.	The potential converter station location provided in Appendix B, Figure B-2 is the indicative location of the Project 1 HVDC converter OSP. The facility's design will implement mitigation measures to reduce impacts on fish stocks, as stated in the NPDES permit application. The HVDC converter station will not use traveling water screens, and the cold-water intake system will include a bar rack and inline pump filter screens. ECOmon survey data were assessed and used in the SouthCoast Wind NPDES permit application. SouthCoast Wind and the HVDC designers are also considering the available data in COP Appendix M, Benthic and Shellfish Resources Characterization Report, and COP Appendix E, MSIR, while working with the EPA through the NPDES permitting process to develop the HVDC design. The HVDC converter station will not be placed on any hard-bottom habitat and will be located outside of the Enhanced Mitigation Area defined in the EIS.
BOEM-2023-0011-0185-0115	Section 3.5.6: Marine Mammals EIS Section: 3.5.6 PDF Page: Global Comment: Overall there is very little mention of project decommissioning and how each of the impacts will affect marine mammals during that phase. Be sure to include this phase of the project under each IPF. As an example how will the amount of lighting change during decommissioning?	The EIS has been revised to include more detail on effects related to the Decommissioning Phase of the Project where applicable. Based on Section 3.5.6, *Marine Mammals*, BOEM anticipates that operational lighting effects on marine mammals would be negligible; thus, effects of lighting during the decommissioning phase of the Project would also be considered negligible.
BOEM-2023-0011-0185-0116	EIS Section: 3.5.6 PDF Page: Global Comment: As you are aware after independent review and a determination of sufficiency NOAA's National Marine Fisheries Service (NMFS) intends to adopt this FEIS for purposes of fulfilling our	Thank you for the suggested resource. Reusable content has already been developed with NMFS review and input, please coordinate within your agency accordingly for additional information. Accordingly, the SouthCoast Wind EIS has been

Comment No.	Comment	Response
	independent responsibilities under the National Environmental Policy Act (NEPA) to support our decision of whether to issue an incidental take authorization to SouthCoast Wind allowing the take of marine mammals. To improve the analysis directly related to our action NMFS recently provided BOEM extensive edits to the Marine Mammals section of Chapter 3 of the Ocean Wind draft PDEIS. NMFS requests all edits provided on the Ocean Wind draft FEIS be incorporated into the SouthCoast Wind FEIS. This includes an additional determination on the effects of the No Action Alternative (i.e. not approving the Construction and Operations Plan) on marine mammals that is comparable to the effect determinations for each Alternative. Further we recently learned BOEM is developing reusable content directly applicable to the acoustic analysis on the impacts of marine mammals. NMFS requests the opportunity to review this content and that any resulting analysis be incorporated into all FEISs including SouthCoast Wind. Given the substantial changes likely to occur we also request the opportunity to review the SouthCoast Wind FEIS again prior to it being published.	updated throughout based on the reusable content from NMFS to ensure that the discussions and analyses under *Alternative A – No Action Alternative* is presented more consistently and conforms with other BOEM EIS documents. Further, the sections under *Alternative B – Proposed Action* have also been revised extensively based on the recent acoustic modeling updates in the MMPA Incidental Take Authorization (ITA) (December 2023) and are in alignment with the analyses in the SouthCoast Wind BA.
BOEM-2023-0011-0185-0117	EIS Section: 3.5.6 PDF Page: 321 Comment: Please explain why the marine mammal geographic analysis area is limited to "the majority of movement ranges" and does not encompass all movement of all analyzed species. Because this GAA is the basis for the quantity and location of the activities listed in "Planned and ongoing activities" which is a major component of the cumulative effects analysis an explanation for this approach is important. NMFS has also identified this issue in other ongoing offshore wind EISs.	The use of the selected geographic analysis area is in keeping with the precedent set by previous offshore wind EISs. The current geographic analysis area sufficiently captures the majority of the movement range of the marine mammal species of focus, and a revision of the geographic analysis areas area is not expected to add additional impacts to the “planned and ongoing activities” that are not currently discussed in this EIS.
BOEM-2023-0011-0185-0118	EIS Section: 3.5.6.1 PDF Page: 323 Comment: The DEIS references Appendix B for "summary table of species included in the analysis" but the values in Table B-7 (Species information) are outdated based on Hayes et al. 2020 and 2021. The right whale abundance value in the table is 368	The population estimates for marine mammal species other than the NARW were not changed from the 2021 to the 2022 estimates, these figures are still accurate according to the best science. The NARW population estimate in the Appendix B table was updated to reflect the most recent (2022) search

Comment No.	Comment	Response
	which is inconsistent with the abundance values referenced elsewhere and the best available science. Please update Table B-7 with information from the publicly available draft 2022 SARs.	and rescue (SAR) efforts (published Hayes et al. 2023) and cited accordingly.
BOEM-2023-0011-0185-0119	EIS Section: 3.5.6.1 PDF Page: 323 Comment: Please indicate the species for which abundance and density values were derived from Palka et al. (2017). Abundance values are available in the draft 2022 SARs and density values are available using the Duke habitat-based cetacean density models. Please clarify why it was necessary to use Palka et al. (2017) values given the availability of these other data sources.	The results of the Atlantic Marine Assessment Program for Protected Species (AMAPPS) studies from the Palka et al. (2017) reference are being used to supplement information from SARs and density models in order to give a more holistic view of marine mammal populations. The Palka et al. (2017) information is not being used as a replacement for other data sources.
BOEM-2023-0011-0185-0120	EIS Section: 3.5.6.1 PDF Page: 323 Comment: At the end of the middle paragraph please note that the New England Aquarium aerial surveys have continued to the present day.	Text has been added to the paragraph to note that the New England Aquarium aerial surveys are currently ongoing.
BOEM-2023-0011-0185-0121	EIS Section: 3.5.6.1 PDF Page: 323 Comment: At the last paragraph on the page please correct the description of the AMAPPS survey coverage area. Most of the AMAPPS shipboard surveys have been concentrated further offshore but aerial surveys regularly cover that area with some shipboard surveys focused directly in the wind energy areas.	The text in the paragraph has been edited to note that aerials surveys regularly cover the project area, and that certain shipboard surveys focus on wind energy areas.
BOEM-2023-0011-0185-0122	EIS Section: 3.5.6.1 PDF Page: 323 Comment: Aside from the Duke University modeling the AMAPPS program AMAPPS has also conducted density models. Please cite the appropriate papers and website with regards to these efforts (for example https://apps-nefsc.fisheries.noaa.gov/AMAPPSviewer/ (Hyperlink: https://apps-nefsc.fisheries.noaa.gov/AMAPPSviewer/) could also cite Chavez et al 2019 DOI: 10.1038/s41598-019-42288-6) (Hyperlink: https://www.nature.com/articles/s41598-019-42288-6)	The AMAPPS Spatial density visualization tool has been cited as Palka et al. (2021). The habitat-density modeling done by Chavez-Rosales et al. (2019) has also been referenced.

Comment No.	Comment	Response
BOEM-2023-0011-0185-0123	EIS Section: 3.5.6.1 PDF Page: 324 Comment: Please clarify the difference between the modeled density peaks of sperm whales. Two different months/time frames are given with two different values. It is not clear if these were from the same time frame and there were two different peaks or if the second value was reporting on a different time frame or model.	This was an error; the first value is the density of sperm whales within the Lease Area. The second value is the density of sperm whales on Nantucket Shoals; however, the wrong value was recorded. This has been clarified in the text and the corrected values are now presented.
BOEM-2023-0011-0185-0124	EIS Section: 3.5.6.1 PDF Page: 324 Comment: Please update with more recent AMAPPS survey data (beyond 2010-2013) in the Threatened and Endangered Marine Mammals section. There have been several AMAPPS surveys since 2013. https://www.fisheries.noaa.gov/resource/publication-database/atlantic-marine-assessment-program-protected-species.	Sightings of blue, fin, sei, and sperm whales have been updated to reference data from the AMAPPS II surveys from 2015 to 2019. Referenced as Palka et al. (2021).
BOEM-2023-0011-0185-0125	EIS Section: 3.5.6.1 PDF Page: 324 Comment: Please consider including an explanation earlier in the text in this chapter about why Nantucket Shoals is important and how it relates to the project area (i.e. the lease area and ECCs) and GAA.	Discussion of Nantucket Shoals as an important habitat for marine species is discussed earlier in the EIS (Executive Summary Section ES.4.4, and Chapter 2, Section 2.1.4) as well as in the BA and EFH Assessment.
BOEM-2023-0011-0185-0126	EIS Section: 3.5.6.1 PDF Page: 325 Comment: Please revise the following text for clarity: "highest number of days of acoustic detections in the winter and spring; with 22 to 67 days of acoustic detections from November to February and again from March to April." It is not clear how "22 to 67" relates to the months in this text.	The number of days of acoustic detections were based off a range (1–3 days; 4–21 days; 22–67 days) captured during each season (Winter – November to February; Spring – March to April) when NARWs were detected at its highest peak. Please see Atlantic Marine Assessment Program for Protected Species: FY15–FY19 (noaa.gov), p. 189 for further clarification.
BOEM-2023-0011-0185-0127	EIS Section: 3.5.6.1 PDF Page: 325 Comment: The draft 2022 SARS (Hayes et al. 2023) provides a NARW abundance estimate of 338. Please correct the statement "2022). The draft 2022 NMFS stock assessment report gives a population estimate of 365 NARWs (Hayes et al. 2022)."	The statement in the FEIS has been revised with the updated NARW abundance estimate (365–338) based on the most recent 2022 Marine Mammals Stock Assessment Report (Hayes et al. 2023).
BOEM-2023-0011-0185-0128	EIS Section: 3.5.6.1 PDF Page: 325 Comment: Listed "NAWR UME up to 92 individuals." Please correct the acronym to NARW.	This typographical error has been corrected in the Final EIS.

Comment No.	Comment	Response
BOEM-2023-0011-0185-0129	EIS Section: 3.5.6.1 PDF Page: 325 Comment: Please update the NARW UME values to reflect the most current information immediately prior to publication of the FEIS.W	The Final EIS has been revised with the updated total number of NARW unusual mortality events (UMEs) based on the data reported in https://www.fisheries.noaa.gov/national/marine-life-distress/2017-2024-north-atlantic-right-whale-unusual-mortality-event (accessed October 2024).
BOEM-2023-0011-0185-0130	EIS Section: 3.5.6.1 PDF Page: 325 Comment: The final sentence of the NARW population estimate paragraph states that NARW population size is fewer than 350 individuals and cites NOAA Fisheries. Earlier in the paragraph there are two models discussed one reporting a population estimate of 336 individuals and one reporting a population 365 the second being above 350. Please either remove the statement that there are fewer than 350 individuals or clearly state the number/estimate that you are moving forward with. This is repeated on PDF page 354.	These sections on the EIS have been revised with the appropriate NARW abundance estimate of 338 individuals based on the most recent 2022 Marine Mammals Stock Assessment Report (Hayes et al. 2023). Statements indicating a range “under/fewer than 350 individuals” rather than the actual abundance estimate have been removed for clarity.
BOEM-2023-0011-0185-0131	EIS Section: 3.5.6.1 PDF Page: 325-326 Comment: Consider different citation other than Palka et al. (2021) for acoustic detections.	Data from AMAPPS (Palka et al. 2017, 2021) are the best publicly available source that provides the most current density estimates (via acoustic detection) on NARW in the Atlantic Ocean. Along with AMAPPS data, density models reported by the Duke University Marine Geospatial Ecology Laboratory (Roberts et al. 2022a–m) are also used throughout the sections to provide modeled density estimates for marine mammals.
BOEM-2023-0011-0185-0132	EIS Section: 3.5.6.1 PDF Page: 326 Comment: Please specify whether the peak density value (NARW/nm^2) in November and December was the same as the density from January to May. If not provide the value.	Peak density values (NARW/nm^2) in November and December were the same as the density from January to May. The text in this section has been revised to reflect this.
BOEM-2023-0011-0185-0133	EIS Section: 3.5.6.1 PDF Page: 326 Comment: Please include the fact that NARW residency time in the MA and RI/MA WEAs from December through May tripled to 13 days during the two study periods 2011-2015 to 2017-2019 (Quintana-Rizzo et al. 2021).	The EIS has been revised to include the modeled residency time of NARWs in the Massachusetts and Rhode Island wind energy areas (WEAs) based on the Quintana-Rizzo et al. (2021) data.

Comment No.	Comment	Response
BOEM-2023-0011-0185-0134	EIS Section: 3.5.6.1 PDF Page: 326 Comment: At the end of the paragraph beginning "Thus NARW observations..." please add "Right whales have been observed feeding in this area in all seasons in southern New England."	The EIS has been revised to include the statement that NARWs have been observed feeding in all seasons in southern New England (O'Brien et al. 2022).
BOEM-2023-0011-0185-0135	EIS Section: 3.5.6.1 PDF Page: 326 Comment: In the last sentence of the first paragraph please remove reference to a spring breeding period which is incorrect.	The EIS has been revised and the statement alluding to foraging during spring breeding period at Brayton Point ECC has been removed.
BOEM-2023-0011-0185-0136	EIS Section: 3.5.6.1 PDF Page: 326 Comment: Please note that right whale critical habitat has not been updated since 2016 and right whale habitat use particularly in southern New England has shifted significantly in recent years.	This comment has been noted. The EIS and other submittals will be updated, wherever applicable, regarding NARW critical habitat and habitat use when new data/information become available.
BOEM-2023-0011-0185-0137	EIS Section: 3.5.6.1 PDF Page: 327 Comment: Please update the humpback whale and minke whale UME values to reflect the most current information immediately prior to publication of the FEIS.	The EIS has been revised with the updated total number of humpback whale and minke whale UMEs based on the data presented in https://www.fisheries.noaa.gov/national/marine-life-distress/2016-2024-humpback-whale-unusual-mortality-event-along-atlantic-coast (accessed October 2024).
BOEM-2023-0011-0185-0138	EIS Section: 3.5.6.1 PDF Page: 329 Comment: In the MMPA ITA application SouthCoast Wind did not include harp seals as a species likely to occur in the project area. Please consider removing references to harp seals.	The harp seal is an uncommon species in the Project area, which means it occurs in low numbers or on an irregular basis. While there are insufficient data to estimate the population size in U.S. waters, the whole population is estimated at 7.6 million, and harp seal occurrences have been increasing in the northeastern United States since the 1980s (CRMC 2010; Hayes et al. 2022). Harp seal was included in the noise modeling that went into the MMPA ITA application; thus, BOEM sees no reason to exclude this species' information from the EIS. Clarifications regarding its population distribution were added.
BOEM-2023-0011-0185-0139	EIS Section: 3.5.6.1 PDF Page: 331 Comment: Please remove the equations in Table 3.5.6-5 and references to the equations used to calculate thresholds based on effects observed in 50 percent of exposed animals. Neither NMFS nor SouthCoast consider these equations when estimating the number of animals that might be exposed to UXO	The Final EIS has been revised with the updated equation based on the more conservative 1 percent threshold. Any statements referring to the equation have also been updated.

Comment No.	Comment	Response
	detonations or any related mitigation. Retaining the equations in the DEIS may be confusing for readers. This is an example of the text that was revised for the Ocean Wind EIS which should be revised here based on those updates (see global comments for Section 3.5.6).	
BOEM-2023-0011-0185-0140	EIS Section: 3.5.6.3 PDF Page: 335 Comment: Please consider creating a bullet point that provides more detail about the site assessment surveys using HRG equipment. Simply saying "site assessments" does not provide enough information.	The statement in the EIS has been revised to include a bulleted list of site characterization activities that could potentially affect marine mammals.
BOEM-2023-0011-0185-0141	EIS Section: 3.5.6.3 PDF Page: 336 Comment: Please add UXO detonations to the list of offshore wind activities that could generate underwater noise and discuss the potential impacts of UXO detonations later in the text.	The statement in the EIS has been revised to include UXO detonations in the list of offshore wind activities that generate underwater noise. A more detailed discussion of UXO detonations is discussed in its own subsection under *Noise*.
BOEM-2023-0011-0185-0142	EIS Section: 3.5.6.3 PDF Page: 337 Comment: Please revise "This act" to say "The MMPA."	This statement has been corrected in the Final EIS for clarity.
BOEM-2023-0011-0185-0143	EIS Section: 3.5.6.3 PDF Page: 337 Comment: Need to add earlier that Level A harassment may also include "other non-auditory injury not leading to serious injury or mortality." This becomes important for the UXO discussion that needs to be added.	The sentence on Level A harassment has been updated to include the statement "other non-auditory injury not leading to serious injury or mortality."
BOEM-2023-0011-0185-0144	EIS Section: 3.5.6.3 PDF Page: 337 Comment: Need to revise text in parentheses to say "(and other non-auditory injury not leading to serious injury or mortality)." This parenthetical addition a response to a comment on the PDEIS presently makes is sound like this words in the parentheses are describing PTS but the correction is meant to indicate that UXO detonations part of offshore wind activities could cause different forms of Level A harassment including gastrointestinal or lung injury.	Please see response to comments BOEM-2023-0011-0185-0143 and BOEM-2023-0011-0185-0145.
BOEM-2023-0011-0185-0145	EIS Section: 3.5.6.3 PDF Page: 337 Comment: As commented on for the PDEIS we still suggest that it is important that the "Physiological effects" section include more extensive	Subsections under *Noise* have been added to include *Non-auditory injury*. The sections under *UXO Detonations* and *Summary Statement for Noise* have also been extensively

Comment No.	Comment	Response
	discussion on mortality serious injury and stress. Please include.	revised to include the physiological effects of *UXO detonation* to marine mammals.
BOEM-2023-0011-0185-0146	EIS Section: 3.5.6.3 PDF Page: 337 Comment: The following sentence should be edited: "While experiencing either TTS the hearing threshold rises and a sound must be louder to be detected." This also describes PTS so please add "or PTS" after TTS.	This statement in the EIS has been revised as requested.
BOEM-2023-0011-0185-0147	EIS Section: 3.5.6.3 PDF Page: 341 Comment: The concluding statement that "seals are likely to exhibit no detectable response or mild orientation responses to impact pile- driving activities" is not supported by the previous examples. All citations above show that seal abundance was greatly reduced during pile driving activities in radii up to tens of km. Seals were all were found to return after construction ceased but all exhibited a behavioral response to pile driving activities.	This statement in the EIS has been revised to say that seals generally exhibit moderate, but temporary behavioral responses to pile-driving activities.
BOEM-2023-0011-0185-0148	EIS Section: 3.5.6.3 PDF Page: 345 Comment: The potential for overlapping UXO detonations from nearby projects being unlikely is not a conclusion that can be drawn by the previous sentence stating that the number and location of detonations are unknown.	The section discussing UXO detonations in the No Action Alternative has been revised extensively in the Final EIS. The conclusions for UXO detonation under No Action have been revised to state that with mitigative measures in place, the impacts associated with UXO detonations would be minor and similar to those described for the Proposed Action.
BOEM-2023-0011-0185-0149	EIS Section: 3.5.6.3 PDF Page: 346 Comment: Please provide more detail as to why the impacts for NARW would be minor and impacts for all other marine mammals in the low-frequency hearing group would be moderate.	The section under No Action Alternative discussing the Summary Statement for Noise has been revised to provide clarity. The concluding statement on noise has been corrected to state that noise-generating sources would result in moderate, short-term impacts on low-frequency cetaceans (LFCs), mid-frequency cetaceans (MFCs), high-frequency cetaceans (HFCs) and pinnipeds. Similarly, while impacts would have population-level effects on the NARW, with implementation of minimization measures expected from ongoing offshore wind activities, impacts would likely be moderate.

BOEM-2023-0011-0185-0150	EIS Section: 3.5.6.3 PDF Page: 346 Comment: This section is missing an assessment of entrainment risk of marine mammal prey from the HVDC OSP(s). Please add a section relative to this risk. Heated effluent is assessed under Accidental Releases though these releases are regular as opposed to accidental. Consider revising this.	The section on *Cumulative Impact of the No Action Alternative* under *Accidental Releases and Discharges* has been revised to include the entrainment risk of marine mammal prey from HVDC OSPs. Impacts from actions related to accidental release and discharges from offshore wind activities, such as entrainment of marine mammal prey, would likely be minor for marine mammals, and moderate for NARW; however, with the application of operational mitigative measures (e.g., flow reduction, physical barriers) that would be required from developers, impacts would be minimized and would be expected to be of low intensity and localized.
BOEM-2023-0011-0185-0151	EIS Section: 3.5.6.3 PDF Page: 346 Comment: The phrase "...the models would be distinguishable relative to natural variability in oceanographic conditions..." does not properly characterize the issue. There are cases where effects may be different than natural variability. Even if the magnitude is within the range of inter-annual variability the direction spatial changes and consistency of these changes may not be. Please revise	Text has been revised to clarify findings of Daewel et al. (2022) where primary production changes were recorded locally at the wind-farm scale, but region-wide averages in estimated annual primary productivity remained almost unchanged.
BOEM-2023-0011-0185-0152	EIS Section: 3.5.6.3 PDF Page: 347 Comment: Daewel et al. (2022) does not show that impacts on primary productivity are not expected to be different than natural variability and instead reports that spatial patterns are likely to change.	Text has been revised to clarify findings of Daewel et al. (2022) where primary production changes were recorded locally at the wind-farm scale, but region-wide averages in estimated annual primary productivity remained almost unchanged.
BOEM-2023-0011-0185-0153	EIS Section: 3.5.6.3 PDF Page: 347 Comment: The discussion of the Golbazi et al. 2022 paper is misleading please revise. When quoting that "...meteorological changes at the surface…will be nearly imperceptible…" this is primarily referencing the difference in air temperature just above the water's surface which was the primary focus of the paper. The focus of the paper is not on oceanographic impacts. These studies do not necessarily cast doubt on the oceanographic conclusions from Daewel et al. 2022 as stated in the draft BA because the Daewell study focuses on	Text has been revised to report the implications of the findings of Golbazi et al. (2022) specific to potential changes to near-surface atmospheric properties, without contrasting to the Daewel et al. (2022) study.

Comment No.	Comment	Response
	atmospheric effects rather than hydrodynamic or oceanographic effects.	
BOEM-2023-0011-0185-0154	EIS Section: 3.5.6.3 PDF Page: 347 Comment: In the last sentence on the page please note that primary productivity could decrease also.	Generally, primary production in the summer in this region is nutrient-limited, so increased mixing would be likely to bring nutrients to the surface and increase production.
BOEM-2023-0011-0185-0155	EIS Section: 3.5.6.3 PDF Page: 348 Comment: At the end of the first full paragraph the description of the scale of impacts could be appropriate if discussing the impacts of the turbine structures directly (not the extraction of wind energy from the system). The use of the term "hydrodynamic" is not always used consistently in the document as meaning impacts from a static feature (i.e. turbine structure) on water and currents.	Please see response to comment BOEM-2023-0011-0185-0002. Edits have been made to clarify use of "hydrodynamic."
BOEM-2023-0011-0185-0156	EIS Section: 3.5.6.3 PDF Page: 349 Comment: Please provide an updated source for percentage of NARW that show evidence of entanglement. One example would be the NOAA Fisheries North Atlantic Right Whale Page (https://www.fisheries.noaa.gov/species/north-atlantic-right-whale) that states "NOAA Fisheries and our partners estimate that over 85 percent of right whales have been entangled in fishing gear at least once."	The statement in the EIS that discusses NARW entanglement has been revised to include a more recent report based on the suggested source.
BOEM-2023-0011-0185-0157	EIS Section: 3.5.6.3 PDF Page: 350 Comment: Appendix D indicates that ongoing and planned offshore wind activities will likely include mitigation measures similar to those that have been proposed by this applicant and by the cooperating agencies. This includes vessel speed restriction. Please modify the analysis under the "Traffic" section to accurately represent the assumptions regarding mitigation made in Appendix D which are used to influence the impact determinations of Alternative A.	The sections under *Traffic (vessel strike*) under No Action Alternative in the EIS have been extensively revised, and analysis of Traffic has been updated to include examples of mitigative measures similar to those described in Appendix G, as would be required from developers for offshore wind activities.

BOEM-2023-0011-0185-0158	EIS Section: 3.5.6.3 PDF Page: 353 Comment: When analyzing the potential impacts from Port Utilization it appears that this IPF is being conflated with Vessel Traffic (and Noise to some extent). Please clarify how port utilization itself excluding vessel traffic would impact marine mammals. If the actual IPF of concern regarding port utilization activities is vessel traffic then perhaps port utilization vessel traffic should be included in the Vessel Traffic IPF.	The section on *Port Utilization* under *No Action Alternative* has been revised in the Final EIS to discuss infrastructure upgrades and port expansions at larger ports such as those planned by the Port of Massachusetts and Port of Virginia (based on Appendix D, *Planned Activities Scenario*) and that offshore wind activities would only make up a small portion of the activities at these ports. Further clarification was made by stating that the realized impacts on marine mammals associated with port utilization would be through increased vessel interaction, exposure to noise, and localized turbidity plumes from dredging (and referred to those related sections for the IPF-specific discussions).
BOEM-2023-0011-0185-0159	EIS Section: 3.5.6.3 PDF Page: 354 Comment: The text: "From 2013 to 2017 the minimum rates of human-caused mortality for sei whales fin whales and NARWs were calculated at 1 2.35 and 6.9 individuals per year respectively" is outdated. Please revise with more recent information.	This section in the EIS has been updated to report the latest human-caused mortality rates for sei whales, fin whales (Hayes et al. 2022), and NARWs (Hayes et al. 2023) based on the most recent Marine Mammals Stock Assessment Reports. https://www.fisheries.noaa.gov/national/marine-mammal-protection/marine-mammal-stock-assessment-reports-region
BOEM-2023-0011-0185-0160	EIS Section: 3.5.6.4 PDF Page: 356 Comment: Please explain how HRG surveys are considered a measure to minimize impacts on marine mammals. NMFS disagrees that this statement in the DEIS is true.	The statement was meant to say “HRG survey-specific mitigation measures” such as pre-start clearance and shutdown zones, as described in detail in Appendix G, *Mitigation and Monitoring*. The Final EIS has been revised to correct this statement.
BOEM-2023-0011-0185-0161	EIS Section: 3.5.6.4 PDF Page: 356 Comment: The phrase "until the PSO has reported no marine mammals in the respective shutdown zone" should be revised to say "until the PSO has reported no marine mammals in the respective clearance zone."	This statement in the Final EIS has been corrected and revised to say that “Ramp-up activities would not be activated until the PSO has reported no marine mammals in the respective clearance zone” consistent with the mitigation measures in Appendix G, *Mitigation and Monitoring*.

BOEM-2023-0011-0185-0162	EIS Section: 3.5.6.4 PDF Page: 356 Comment: Please incorporate consideration of the proposed vessel speed rule when discussing vessel speed.	Thank you for the comment. No change is required at this time. BOEM has already proposed a 10-knot speed restriction for all vessel sizes operating port-to-port between November 1 and April 30, as well as additional conditions that go above and beyond what NMFS currently requires through regulation.
BOEM-2023-0011-0185-0163	EIS Section: 3.5.6.4 PDF Page: 357 Comment: NMFS and BOEM have yet to determine whether nighttime pile driving will be allowed. Please revise this phrase to account for the possibility that nighttime pile driving may not be approved by NMFS.	Thank you for the comment. No change is required at this time. BOEM and NMFS are assessing the proposed project presented by the lessee. Any decisions, including those regarding nighttime pile driving, are subject to the outcomes of consultations, incidental take regulations issued by NMFS under the MMPA, and ultimately BOEM decision-makers that will approve, disapprove, or approve the COP with conditions. NMFS is considering allowing nighttime pile driving under some circumstances, and BOEM acknowledges that this conversation would continue through consultation and between NMFS and the applicant that may affect the final conditions required for the Project.
BOEM-2023-0011-0185-0164	EIS Section: 3.5.6.4 PDF Page: 357 Comment: Please add "and UXO detonations" after "pile driving" in the phrase "avoiding pile driving activity between January 1 and April 30."	This statement has been revised in the EIS to include UXO detonations as one of the Project-related activities bound by a seasonal restriction.
BOEM-2023-0011-0185-0165	EIS Section: 3.5.6.5 PDF Page: 357 Comment: In the MMPA ITA application SouthCoast Wind proposed using vibratory pile driving to install most foundation piles. Please remove "if used."	The statement has been corrected and the phrase “if used” for vibratory pile driving has been removed with concurrence to Appendix C, *Project Design Envelope and Maximum-Case Scenario*.
BOEM-2023-0011-0185-0166	EIS Section: 3.5.6.5 PDF Page: 358 Comment: "Each WTG requires 1 monopile or 4 to 8 pin piles" does not align with what SouthCoast proposed. Each WTG foundation would require installation of 4 pin piles if piled jacket foundations are installed. OSP foundations may require more than 4 pin piles. Please correct this here and throughout as appropriate.	The Final EIS has been updated throughout to reflect the latest installation scenarios that were used for the noise modeling described in the December 2023 ITR application.
BOEM-2023-0011-0185-0167	EIS Section: 3.5.6.5 PDF Page: 358 Comment: Please correct the phrase "with each pin pile or monopile requiring 4 or 2 hours of driving to install respectively." This is not the timing	The section *Noise: Pile Driving* under *Alternative B - Proposed Action* has been updated throughout to reflect the latest installation parameters as outlined in the MMPA ITA

Comment No.	Comment	Response
	SouthCoast proposed in their MMPA ITA application. Instead SouthCoast assumed each monopile would require up to 20 minutes of vibratory pile driving and 4 hours of impact pile driving. Each pin pile would require up to 90 minutes of vibratory pile driving and 2 hours of impact pile driving. In addition there would be a 2-4 hour period after vibratory pile driving when the hammer would be changed from vibratory to impact.	(December 2023). The modeled parameters for foundation installation have been corrected and now states that each WTG requires one monopile or four pin piles for jacket foundation. Monopile installation requires 4 hours of piling (including 20 minutes of vibratory piling). Pin-pile installation requires 2 hours of piling (including 90 minutes of vibratory piling). Both monopile and pin pile installations would require an additional 1 hour of pre-start clearance period and 4 hours to move to the next piling location.
BOEM-2023-0011-0185-0168	EIS Section: 3.5.6.5 PDF Page: 358 Comment: SouthCoast is no longer considering potential installation of 11-m monopiles and 2.9-m pin piles (the "Realistic" scenario) in their MMPA ITA application but is still considering installation of 16-m monopile foundations and 4.5-pin piles for piled jacket foundations. Please update the DEIS to reflect the most current maximally impactful construction scenarios SouthCoast is considering (included in the MMPA ITA application).	The EIS has been updated throughout to reflect the latest installation scenarios that were used for the noise modeling described in the December 2023 ITR application. Information pertaining to the previously modeled scenarios with smaller-diameter piles has been removed.
