The long-term presence of WTG structures could displace marine mammals from preferred habitats or alter movement patterns, potentially changing exposure to commercial and recreational fishing activity. The evidence for long-term displacement is unclear and likely to differ between marine mammal species. For example, Long (2017) studied marine mammal habitat use around an ocean energy testing facility and found evidence of displacement during construction, but habitat use appeared to return to normal during facility operation. He cautioned that these findings were not definitive and additional research was needed. In contrast, Tielmann and Carstensen (2012) observed clear long-term (greater than 10 years) displacement of harbor porpoises from commercial wind farm areas in Denmark. Displacement effects remain a focus of ongoing study (Kraus et al. 2019). Other studies have documented apparent increases in marine mammal density around wind energy facilities. For example, Russel et al. (2014) found clear evidence that seals were attracted to a European wind farm, apparently by the abundant concentrations of prey supported by artificial reef effects. Gray seals are particularly susceptible to entrapment in trawl fisheries (Lyssikatos 2015). If commercial trawling were to occur near wind farms, increased interactions and resulting mortality of gray seals could occur.

Hayes et al. (2021, 2022) note that marine mammals are following shifts in the spatial distribution and abundance of their primary prey resources driven by increased water temperatures and other climate-related impacts. These range shifts are primarily oriented northward and toward deeper waters. The widespread development of offshore renewable energy facilities could facilitate climate change adaptation for certain marine mammal prey and forage species. The artificial reefs created by these structures form biological hotspots that could support species range shifts and expansions and changes in biological community structure (Degraer et al. 2020; Methratta and Dardick 2019; Raoux et al. 2017). In contrast, broadscale hydrodynamic impacts could alter zooplankton distribution and abundance (van Berkel et al. 2020). There is considerable uncertainty as to how these broader ecological changes would affect marine mammals in the future, and how those changes will interact with other human-caused impacts. The effect of these reef effects and hydrodynamic impacts on marine mammals and their habitats under the No Action Alternative could be beneficial or adverse, and their significance could range from **minor** adverse, negligible, or **moderate** beneficial. Impacts to specific species, such as NARW, are uncertain and would depend on several factors, including the nature and extent of effects to forage resources and the status of the affected population and sensitivity to effects to individuals.

The presence of structures could also concentrate recreational fishing around foundations, potentially increasing the risk of marine mammal entanglement in both lines and nets and increasing the risk of injury and mortality due to infection, starvation, or drowning (Moore and van der Hoop 2012). Fisheries interactions are likely to have demographic effects on marine mammal species, with estimated global mortality exceeding hundreds of thousands of individuals each year (Read et al. 2006; Reeves et al. 2013; Thomas et al. 2016). These structures could also result in fishing vessel displacement or changes in gear types that lead to changes in marine mammal exposure to fishing effects. For example, a shift from mobile gear to fixed gear could increase in the number and distribution of vertical lines and buoys in the water column, resulting in an increased risk of marine mammal interactions with fishing gear. The likelihood of such shifts and potential resulting effects to marine mammals is uncertain. However, bycatch and harmful interactions are known occur in various gillnet and trawl fisheries throughout New England and the Mid-Atlantic Coast, with hotspots driven by marine mammal density and fishing intensity (Lewison et al. 2014; Morin et al. 2018; NOAA 2021a; 86 *Federal Register* 51970). Entanglement in fishing gear has been identified as one of the leading causes of mortality in NARW and could be a limiting factor in the species' recovery (Knowlton et al. 2012). Johnson et al. (2005) report that 72% of NARWs show evidence of past entanglements. Additionally, recent literature indicates that the proportion of NARW mortality attributed to fishing gear entanglement is likely higher than previously estimated from recovered carcasses (Pettis et al. 2021). Entanglement could also be responsible for high mortality rates in other large whale species (Read et al. 2006). Abandoned or lost fishing gear could get tangled with foundations, reducing the chance that abandoned gear would cause additional harm to marine mammals and other wildlife, though debris tangled with WTG foundations could still pose a hazard to marine mammals. BOEM anticipates that future projects would perform regular inspections to identify and remove derelict fishing gear and other marine debris from offshore structures. These inspections would provide a mechanism for removing harmful marine debris, reducing associated risks to marine mammals.

Although the type and magnitude of effect from displacement and shifts in prey resources due to the presence of structures are largely unknown, the possibility of changes in distribution relative to commercial fishing activity and increased interaction with fishing gear poses the potential for increased risk of entanglement. Should such changes occur, increased risk of entanglement would constitute a **minor** to **moderate** adverse effect on marine mammals, because this stressor is a documented source of injury and mortality. Effects to each marine mammal species would depend on several factors, including the number of individual animals exposed to entanglement effects, the nature of the impact (i.e., injury or mortality), and the status and sensitivity of the affected population to those impacts. In the case of NARW, given that entanglement has been identified as a limiting factor in the species' recovery, the potential for increased exposure to entanglement could pose a significant risk; however, specific EPMs have been developed to minimize risk for NARW (including monitoring, gear identification, and marine debris management; refer to Appendix F for the full list). The risk of entanglement is therefore not considered to result in a greater than **moderate** adverse effect for NARW. It is important to stress that the likelihood of this level of effect is unclear because it is not known if the presence of structures would displace NARW and whether displacement would lead to increased fishing gear exposure. These potential long-term impacts would persist until decommissioning is complete and structures are removed.

Anticipated EPMs would help to offset the potential impact of entanglement within derelict fishing gear or marine debris.

Vessel traffic: BOEM estimates that construction of future offshore wind projects would begin in earnest in 2022 and conclude in 2030. Vessel activity could peak in 2025 with as many as 210 vessels involved in the construction of reasonably foreseeable projects (see Section 3.16.1.1).

Once future projects reach the O&M phase, they would be serviced by crew transport vessels (CTVs) and SOVs making routine trips between the wind farms and port-based O&M facilities. The number and size of CTVs and number of trips per week required for planned maintenance would vary by project based on the number of WTGs. Increased vessel traffic presents a potential increase in collision-related risks to marine mammals. BOEM anticipates that those risks would be minimized by project-specific EPMs and compliance with additional mitigation measures required as a condition of ESA and MMPA compliance. While these measures are likely to be effective in avoiding adverse effects on sensitive species like NARW, they would not eliminate risks to other marine mammal species.

Unplanned maintenance activities would require the periodic use of larger vessels of the same class used for project construction. Unplanned maintenance would occur infrequently dictated by equipment failures, accidents, or other events. Vessel requirements for unplanned maintenance would also likely vary based on overall project size. Unplanned trips would pose similar vessel-related collision risks to marine mammals as for planned trips, but the potential extent and number of animals potentially exposed cannot be determined without project-specific information. Accordingly, adverse effects to marine mammals from increased vessel activity could range from **minor** to **moderate** adverse throughout construction and O&M.

#### 3.15.2.2.3 Conclusions

Impacts of the No Action Alternative. Under the No Action Alternative, BOEM would not approve the RWF COP; Project construction and installation, O&M, and decommissioning would not occur; and potential impacts on marine mammals associated with the Project would not occur. Baseline conditions of the existing environment would remain unchanged. Therefore, not approving the COP would have no additional incremental effect on marine mammals. Similarly, NMFS's No Action Alternative (i.e., not issuing the requested incidental take authorization) would also have no additional incremental impact on marine mammals and their habitat.

Under the No Action Alternative, ongoing stressors and activities contributing to baseline conditions would result in a range of temporary to long-term impacts (disturbance, displacement, injury, mortality, and reduced foraging success) on marine mammals. Climate change would continue to affect marine mammal foraging and reproduction through changes to the distribution and abundance of marine mammal prey. Vessel activity (vessel collisions) and gear utilization associated with ongoing non–offshore wind activities would continue to cause long-term detectable and measurable injury and mortality to individual marine mammals. Impacts to marine mammals from the construction, O&M, and eventual decommissioning of other planned and permitted offshore wind facilities would occur. Underwater noise from pile driving during construction of those projects would result in detectable impacts on marine mammals; however, these impacts would be short term. Accidental releases and discharges, EMF, the presence of structures, cable emplacement and maintenance, port utilization, and lighting would result in long-term negligible or minor impacts on marine mammals. Although impacts on individual marine mammals and their habitat are anticipated from other offshore wind activities, the level of impacts would be minimized due to the EPMs implemented during construction, operation, and maintenance. The No Action Alternative would result in **minor to moderate** impacts on mysticetes (with the exception of NARW), odontocetes, and pinnipeds and could include **minor beneficial** impacts for some species that benefit from increased prey availability.

Because of the low population size for the NARW and continuing stressors, population-level effects on NARWs are occurring. Vessel activity (vessel collisions) and gear utilization associated with ongoing non–offshore wind activities continue to result in long-term population-level impacts. The effects of climate change further exacerbate impacts on NARW. For NARW, the No Action Alternative (in consideration of baseline conditions) would continue to result in **major** long-term impacts. Ongoing offshore wind construction, operation, and maintenance activities would be conducted with applicant-proposed and agency-required mitigation measures developed to avoid and minimize impacts on NARW; therefore, impacts from offshore wind activities are not anticipated to substantially contribute to the major impacts.

Cumulative impacts of the No Action Alternative. Under the No Action Alternative, existing environmental trends and ongoing activities would continue in addition to impacts from planned offshore wind activities. Mysticetes, odontocetes, and pinnipeds would continue to be affected by natural and human-caused IPFs. Planned non–offshore wind activities would also contribute to impacts on marine mammals. Planned non–offshore wind activities include increasing vessel traffic; new submarine cable and pipeline installation and maintenance; marine surveys; commercial and recreational fishing activities; marine minerals extraction; port expansion; channel-deepening activities; military readiness activities; and the installation of new towers, buoys, and piers. BOEM anticipates that planned non–offshore wind activities would result in moderate long-term impacts on marine mammals (with the exception of NARW) primarily driven by ongoing underwater noise impacts, vessel activity (vessel collisions), entanglement, seabed disturbance, and the lack of knowledge regarding any mitigation and monitoring requirements for these planned non–offshore wind activities. BOEM anticipates that the combined ongoing and planned activities would result in moderate impacts on marine mammals (with the exception of NARW, which would remain major). Additionally, the presence of structures could provide **beneficial** impacts on some marine mammal species.

Cumulative impacts to NARW are in many cases more severe than otherwise similar impacts to other marine mammal species. Due to the imperiled status of the population, impacts that lead to loss or reduced fitness of even one individual could compromise the viability of the species, which would constitute a major impact per the definitions provided in Section 3.3. Offshore wind construction, operation, and maintenance activities would be conducted with applicant-proposed and agency-required mitigation measures developed to minimize impacts on NARW; therefore, impacts from offshore wind activities are not anticipated to substantially contribute to the existing major impacts from baseline conditions.

On this basis, BOEM anticipates that the cumulative impacts of the No Action Alternative would result in **minor** to **moderate** impacts on mysticetes, odontocetes, and pinnipeds, with the exception of the NARW, on which impacts would be **major**. Impacts on individual NARWs could have population-level effects, and it is unknown whether the population can sufficiently recover from the loss of an individual to maintain the viability of the species.

The No Action Alternative would forgo any long-term monitoring that Revolution Wind has committed to, or would be required to perform, the results of which could provide an understanding of the effects of offshore wind development, benefit future management of these resources, and inform planning of other offshore developments. BOEM acknowledges, however, that other ongoing and future monitoring and surveys could provide similar data to support similar goals.

### 3.15.2.3 Alternative B: Impacts of the Proposed Action on Marine Mammals

Under the Proposed Action, baseline conditions for marine mammals (see Section 3.15.1) would continue to follow current regional trends within the GAA. Under Alternative B, BOEM would approve the COP for the Proposed Action. The impacts of each IPF from the construction and installation, O&M, and conceptual decommissioning of the Proposed Action would be incremental to and would compound the impacts of baseline conditions on each marine mammal population considered in this EIS (see Table 3.15-2). These effects are described below.

#### 3.15.2.3.1 Construction and Installation

#### Offshore Activities and Facilities

<u>Anchoring and new cable emplacement/maintenance:</u> Effects on marine mammals from anchoring and cable emplacement activities during Project construction would primarily result from noise and disturbance related to vessel activity and exposure to suspended sediments from seafloor disturbance. Potential effects from exposure to vessel activity and suspended sediments from seafloor disturbance are described below under the vessel traffic and sediment deposition and burial IPFs, respectively. Entanglement risks to marine mammals from vessel anchoring and cable emplacement are not anticipated. Only larger construction and O&M vessels would anchor to the seafloor using large heavy anchor chains. Per the COP, no divers would be used and no lines or rigging are anticipated for cable installation and maintenance. Transmission cables and jet plow umbilicals are large in diameter, relatively inflexible, and under constant tension throughout installation. Therefore, the likelihood of marine mammal entanglement is discountable.

Anchoring and cable emplacement effects could lead to short-term adverse effects on invertebrate and finfish prey species. Effects on marine mammal prey resources are described in detail in Sections 3.6.2.2.1 and 3.13.2.2.1, respectively. While indirect effects to fish and invertebrate prey resources would occur, these impacts are not likely to significantly affect the availability of prey and forage resources for any marine mammal species and would therefore be **negligible** adverse. Therefore, anchoring and cable emplacement during construction would have **negligible** adverse effects on marine mammals.

<u>Noise:</u> Construction of the RWF and RWEC would produce short-term underwater and airborne noise with the potential to affect marine mammals. Construction noise sources include impact and vibratory pile driving, HRG surveys, UXO detonation, construction vessels, and helicopters and fixed-wing aircraft. The COP includes EPMs that the Project has committed to implementing and are described in Appendix F, Table F-1.

Impact pile driving would be used to install up to 100 RWF WTG and two OSS foundations. Vibratory pile driving could be used to construct the temporary cofferdam at the RWEC sea-to-shore transition. Construction vessels would be used throughout RWF and RWEC construction. Impact hammer installation of the RWF WTG and OSS foundations would produce underwater noise impacts with the greatest amount of exposure and highest potential to cause injury-level effects on marine mammals, based on likelihood of occurrence and extent of impacts.

Vibratory pile driving would generate intense non-impulsive noise impacts. Non-impulsive noise is less likely to cause injury to marine mammals, but the loud, continuous sound field generated by these sources can interfere with, or mask, communication and the ability to detect predators and locate prey (Hatch et al. 2012; Putland et al. 2017). When moving, construction vessels and marine mammals are moving in relation to one another. This tends to limit the duration of exposure such that injury-level effects are unlikely, but exposures exceeding behavioral harassment thresholds could still occur. In contrast, vibratory pile driving used to install the temporary cofferdam at the RWEC sea-to-shore transition site would be stationary. Vibratory pile-driving noise can cause auditory masking effects over great distances. Vessel engines also produce non-impulsive low frequency sound. While lower in intensity than vibratory pile driving, vessel engines operate continuously and can substantially alter the ambient noise environment.

UXOs could also be present within the maximum work area, and if these devices cannot be safely relocated or avoided, they may need to be detonated in place before bed-disturbing construction activities begin. Revolution Wind would follow an industry-standard process that minimizes the number of potential detonations (see COP Appendix G [Ordtek 2021]). These measures range from relocating the activity away from UXO, moving the UXO away from the activity, or cutting the UXO open to deactivate fused munitions or low-order detonation. These measures would be considered prior to in-situ UXO disposal. As of February 2023, 16 UXOs have been identified in the RWEC corridor. Revolution Wind has determined that all 16 devices can be safely avoided by shifting the cable route within the approved installation corridor without the need for detonation (Orsted 2023). However, additional devices of unknown size and location could be discovered during preconstruction surveys or construction that cannot be avoided or safely relocated. BOEM has concluded that the need for UXO detonation cannot be entirely ruled out; therefore, the potential effects of this activity on marine mammals are considered herein. The applicant has developed an assessment of potential underwater noise impacts on marine mammals, sea turtles, and finfish from UXO detonation, considering a range of warhead sizes ranging from 5 to 1,000 pounds (2.3 to 454 kg) (Hannay and Zykov 2022). The analysis presented herein considers impacts from detonation of the largest UXOs potentially occurring in the maximum work area. UXO detonation could overlap with other construction noise, but these effects have not been analyzed.

Underwater noise impacts on marine mammals are evaluated using behavioral and injury-level thresholds for different marine mammal species groups developed by NMFS (GARFO 2020; NOAA 2018) and TTS (i.e., temporary hearing impairment) exposure thresholds developed by the U.S. Navy (2017). Specific injury thresholds are defined for different marine mammal species groups based on hearing sensitivity. These thresholds are summarized in Table 3.15-5. As shown, marine mammals are organized into four groups based on hearing sensitivity, specifically the range of sound frequencies they are most sensitive to. NOAA (2018) has defined dual injury criteria for each group that can be used to evaluate the potential for hearing injury from exposure to different types of noise exposure, such as instantaneous exposure to a single pile strike, cumulative exposure to multiple pile strikes, cumulative exposure to UXO detonation, or cumulative exposure to non-impulsive sources like vibratory pile driving or vessel noise (NOAA 2018). NMFS (NOAA 2018) and the U.S. Navy (2017) have also defined threshold criteria for behavioral and TTS effects from impulsive noise sources and for behavioral effects from non-impulsive noise sources (see Table 3.15-5). The TTS thresholds are used to assess temporary hearing impairment impacts from UXO detonation; the behavioral thresholds are used to assess effects of other construction-related noise (e.g., pile driving, vessel noise).

Revolution Wind evaluated the potential for exposure to UXO-detonation-related noise impacts associated with the onset of lung and gastrointestinal (i.e., non-auditory) injuries ranging from minor up to and including potential mortality (Hannay and Zykov 2022; U.S. Navy 2017). Non-hearing-related injury thresholds are determined by equations that consider animal mass and depth at the time of exposure. Tables 3.15-6 and 3.15-7 present the animal mass estimates for different marine mammal groups and the equations used to calculate non-auditory injury thresholds for UXO detonation. The threshold formulas presented in Table 3.15-7 are based on observed onset of injuries to 1% of individuals in U.S. Navy (2017) test studies. BOEM is not presenting threshold distances for non-auditory injury and mortality from UXO detonation in Table 3.15-5, because animal size and water column position at the time of exposure will vary on a case-by-case basis. Hannay and Zykov (2022) considered a range of potential exposure scenarios and found that non-auditory threshold exposure distances for mitigated UXO detonations were less than those for auditory injury and temporary hearing impairment and within the pre-clearance zones for marine mammals proposed by Revolution Wind. Because the threshold distances for potential auditory injury and temporary hearing impairment will always be larger than those for non-auditory injury for a given marine mammal group, BOEM is relying on the latter to determine the potential for adverse noise impacts. BOEM is applying the guidance and thresholds currently accepted by NOAA (2018) to assess underwater noise impacts. BOEM also recognizes that marine mammal hearing is an evolving science, and improved understanding (e.g., Southall et al. 2019) could lead to future refinements.

**Table 3.15-5. Underwater Noise Exposure Thresholds for Permanent Hearing Injury and Behavioral Disruption by Marine Mammal Hearing Group**

| Hearing Group | Type of Effect | Type of Exposure | Value | Units |
|---|---|---|---|---|
| LFC | Permanent hearing injury | Cumulative SEL (impulsive)* | 183 | SEL dB re 1 μPa²·s |
| | | Cumulative SEL (non-impulsive) | 199 | SEL dB re 1 μPa²·s |
| | | Peak injury (impulsive)* | 219 | dB re 1 μPa |
| | Behavioral harassment/ Temporary hearing impairment | Behavioral (intermittent) | 160 | dB re 1 μPa |
| | | TTS (peak)* | 213 | dB re 1 μPa |
| | | TTS (cumulative SEL)* | 168 | SEL dB re 1 μPa²·s |
| | | Behavioral (continuous) | 120 | dB re 1 μPa²·s |
| MFC | Permanent hearing injury | Cumulative SEL (impulsive)* | 185 | SEL dB re 1 μPa²·s |
| | | Cumulative SEL (non-impulsive) | 198 | SEL dB re 1 μPa²·s |
| | | Peak injury (impulsive)* | 230 | dB re 1 μPa |
| | Behavioral harassment/ Temporary hearing impairment | Behavioral (intermittent) | 160 | dB re 1 μPa |
| | | TTS (peak)* | 224 | dB re: 1 μPa |
| | | TTS (cumulative SEL)* | 170 | SEL dB re 1 μPa²·s |

| Hearing Group | Type of Effect | Type of Exposure | Value | Units |
|---|---|---|---|---|
| | | Behavioral (continuous) | 120 | dB re 1 µPa |
| HFC | Permanent hearing injury | Cumulative SEL (impulsive)* | 155 | SEL dB re 1 µPa²·s |
| | | Cumulative SEL (non-impulsive) | 173 | SEL dB re 1 µPa²·s |
| | | Peak injury (impulsive)* | 202 | dB re 1 µPa |
| | Behavioral harassment/ Temporary hearing impairment | Behavioral (intermittent) | 160 | dB re 1 µPa |
| | | TTS (peak)* | 196 | dB re 1 µPa |
| | | TTS (cumulative SEL)* | 140 | SEL dB re 1 µPa²·s |
| | | Behavioral (continuous) | 120 | dB re 1 µPa |
| Seals and sea lions (Phocids) | Permanent hearing injury | Cumulative SEL (impulsive)* | 185 | SEL dB re 1 µPa²·s |
| | | Cumulative SEL (non-impulsive) | 198 | SEL dB re 1 µPa²·s |
| | | Peak injury (impulsive)* | 218 | dB re 1 µPa |
| | Behavioral harassment/ Temporary hearing impairment | Behavioral (intermittent) | 160 | dB re 1 µPa |
| | | TTS (peak)* | 212 | dB re 1 µPa |
| | | TTS (cumulative SEL)* | 170 | SEL dB re 1 µPa²·s |
| | | Behavioral (continuous) | 120 | dB re 1 µPa |

Note: SEL = sound exposure level.

* The identified values were used in the analysis of UXO detonation effects (Hannay and Zykov 2022; U.S. Navy 2017).

**Table 3.15-6. Representative Calf/Pup and Adult Mass Estimates Used for Assessing Impulse-based Onset of Lung Injury and Mortality Threshold Exceedance Distances**

| Impulse Animal Group | Representative Species* | Calf/Pup Mass (kilograms) | Adult Mass (kilograms) |
|---|---|---|---|
| Baleen whales and sperm whale | Sei whale (*Balaenoptera borealis*)<br>Sperm whale (*Physeter macrocephalus*) | 650 | 16,000 |
| Pilot and minke whales | Minke whale (*Balaenoptera acutorostrata*) | 200 | 4,000 |
| Beaked whales | Gervais' beaked whale (*Mesoplodon europaeus*) | 49 | 366 |
| Dolphins, kogia, pinnipeds, and sea turtles | Harbor seal (*Phoca vitulina*) | 8 | 60 |
| Porpoises | Harbor porpoise (*Phocoena phocoena*) | 5 | 40 |

*Species presented here are representative for the impulse animal group as presented by U.S. Navy (2017). Some species shown and do not necessarily occur within the RWF or RWEC corridor.

**Table 3.15-7. Thresholds for Onset of Non-auditory Injury Based on Observed Effects on 1% of Exposed Animals**

| Hearing Group | Mortality (severe lung injury)* | Slight Lung Injury* | Gastrointestinal Tract Injury |
|---|---|---|---|
| All marine mammals | $103M^{1/3}\left(1+\frac{D}{10.1}\right)^{1/6}$ Pa·s | $47.5M^{1/3}\left(1+\frac{D}{10.1}\right)^{1/6}$ Pa·s | $L_{pk,flat}$: 237 dB |

Source: U.S. Navy (2017).

Notes:

M = animal (adult and/or calf/pup) mass (kilograms) (see Table C.9 in U.S. Navy [2017])

D = animal depth (meters).

* Lung injury (severe and slight) thresholds are dependent on animal mass.

Kusel et al. (2023) and Hannay and Zykov (2022) developed sound source level estimates for monopile installation and UXO detonation activities that could occur under the Proposed Action. They then used those source values to estimate the distance required for that noise to attenuate to the marine mammal exposure thresholds. LGL (2022) reported comparable sound source estimates for vibratory pile driving used for sea-to-shore transition construction. Assessment of construction vessel noise is based on the analysis presented in Denes et al. (2021). The resulting values based on summer modeling conditions, presented in Table 3.15-8, represent a radius extending around each noise source where potential injury and behavioral-level effects could occur. The single strike injury distances apply only to impact pile driving and represent how close a marine mammal would have to be to the source to be instantly injured by a single pile strike. The cumulative injury distances are based on exposure ranges that consider total estimated exposure accounting for animal movement. The behavioral and TTS values are instantaneous exposure distances, meaning that any animal within the effect radius is assumed to have experienced a temporary to short-term adverse effect.

Using the information presented in Tables 3.15-6 and 3.15-7, Hannay and Zykov (2022) also assessed the potential for non-auditory injury (i.e., lung and gastrointestinal injury). As noted, the potential for non-auditory injury is dependent on water depth, animal mass, and device size. Across the range of depths, animal mass, and device sizes assessed, the onset of lung injury may occur within 16 to 2,126 feet of a detonation, and mortality may occur within 16 to 1,158 feet of a detonation. Gastrointestinal injury may occur within 69 to 410 feet of a detonation. These distances assume use of an attenuation system achieving 10-dB sound source reduction. As evident in Table 3.15-6, the potential for auditory injury from UXO detonation typically occurs within a much larger radius around the detonation than the potential for non-auditory injury. However, depending on the device size, it is possible that an individual could experience both non-auditory and auditory injury.

**Table 3.15-8. Distance Required to Attenuate Underwater Construction Noise below Marine Mammal Injury and Behavioral Effect Thresholds by Activity and Hearing/Species Groups, based on Exposure Range (ER95%) Values**

| Construction Activity | Number of Sites | Total Days | Species Group | Distance to Peak Injury Threshold (feet) | Distance to Cumulative Injury Threshold (feet)^ | Distance to Behavioral or Cumulative TTS Effect Threshold (feet) ^ |

^ Distances to thresholds for peak exposure, behavioral effects exposure, and UXO detonation are exposure ranges, which describe the area within which 95% of exposed animals would experience the effect from instantaneous exposure (R95%). Cumulative injury and TTS (i.e., temporary hearing impairment) threshold distances are exposure ranges (ER95%). Exposure ranges account for animal movement and are used to determine the number of animals likely to be exposed to cumulative exposure effects.

* Data from Kusel et al. (2023). Values shown are the range of effect threshold distances across all modeled species in each hearing group for summer installation of 12-m WTG monopiles and 15-m OSS monopiles. Installation scenario for 12-m monopiles is 10,740 strikes/pile at installation rate of three piles/day. Installation scenario for 15-m monopile is 11,563 strikes/pile at installation rate of up to two piles/day. All piles installed with a maximum 4,000-kJ hammer with an attenuation system achieving 10-dB sound source reduction.

† Data from LGL (2022) for a sheet pile cofferdam installed using a vibratory hammer. Distance to threshold estimated assuming the use of AZ-type sheet piles, with a maximum of 56 pile-driving days (for installation and removal). Threshold distances shown do not consider geographic confinement by surrounding shorelines of Narragansett Bay.

‡ HRG survey values are maximum threshold distances for each hearing group for the loudest type of equipment likely to be employed, as reported by LGL (2022).

§ Data from Denes et al. (2021). Analysis considered use of dynamic positioning thrusters by construction vessels. This analysis did not consider the timing, frequency, and duration of noise from background vessel traffic in and near the Lease Area. Noise levels produced by construction vessels are expected to be similar to these background sources.

¶ The range of values shown are the minimum and maximum threshold distances for detonation of UXOs ranging in size from 5 to 1,000 pounds at four modeled sites with 10 dB of sound attenuation (Hannay and Zykov 2022). The 1,000-pound UXO is the largest potential explosive device potentially occurring in the maximum work area.

# Peak and cumulative PTS threshold distances calculated by Hannay and Zykov (2022) for detonation of 5 to 1,000-pound UXOs with 10 dB of sound attenuation. NOAA uses the larger cumulative threshold distance to assess potential PTS (i.e., hearing injury) and TTS (i.e., temporary hearing impairment) exposure resulting from UXO detonation (Hannay and Zykov 2022). Hearing injury and temporary hearing impairment exposure could occur anywhere within zones of exposure ranging from 46,139 to 567,221 acres within and around the maximum work area for the RWF and RWEC. The size of a potential exposure area will vary within this range by hearing group and the type of exposure (i.e., PTS or TTS). The location of detonation impacts and actual likelihood of exposure would depend on where UXOs are encountered.

The PDE for the Proposed Action includes the installation of up to 100 12-meter and two 15-meter monopile foundations using an impact hammer. The installation scenario considered in the acoustic analysis assumes each WTG monopile installation would require up to 10,740 strikes from an impact hammer ranging in energy from 1,000 kJ to 4,000 kJ over 4 hours to achieve desired depth. Up to three WTG monopiles could be installed in 1 day. The 15-meter OSS monopiles would require up to 11,563 strikes from an impact hammer ranging in energy from 1,000 kJ to 4,000 kJ and up to two piles would be installed per day. After each pile is driven to depth, the construction vessel would attach appurtenant platforms and equipment and then reposition to the next foundation site. Additionally, detonation of UXOs within the work area may be required. The UXO exposure distance estimates (presented in Table 3.15-8) reflect the planned use of a noise attenuation system that would reduce the source noise level by an average of 10 dB per hammer strike, which has been demonstrated with currently available technologies under other circumstances (Bellman et al. 2020).

Monopile installation and UXO detonation are the most likely sources of permanent hearing injury and other temporary to short-term effects to marine mammals from Project-related underwater noise. UXO detonation may also result in non-auditory injury (i.e., lung and gastrointestinal tract compression injuries); these effects are dependent on water depth and animal mass (Hannay and Zykov 2022). The likelihood of injury from underwater noise also depends on proximity to the noise source, the intensity of the source, sensitivity to the sound source, and the duration of noise exposure. A summary of the distances required to attenuate impact pile-driving noise for WTG and OSS foundation installation and UXO detonation below exposure thresholds is provided in Table 3.15-8. As shown, the threshold distances for different types of effects varies between marine mammal species depending on hearing sensitivity. For example, a low-frequency cetacean would have to remain within 8,727 feet of a 12-meter monopile installation for 24 hours to experience permanent cumulative hearing injury, referred to as PTS. In contrast, the same animal could immediately experience PTS if it were within 14,009 feet from detonation of a 1,000-pound UXO. Mid-frequency cetaceans and phocid pinnipeds are less sensitive to the intense, low-frequency sounds produced by impact pile driving and would have to be much closer to the source to be injured. For example, phocid pinnipeds would need to remain within less than 1,444 feet of a 12-meter monopile installation for 24 hours to experience cumulative injury. Aversion responses (avoidance of sound levels or acoustic sources that are disturbing or injurious) by marine mammals have been documented, and available information suggests that mobile marine mammals are likely to leave areas where potentially harmful noise effects are occurring (Dunlop et al. 2017; Ellison et al. 2012; Southall et al. 2007). A detailed discussion of noise impacts on marine mammals is provided in Vineyard Wind final EIS Section 3.4.1.1.1 (BOEM 2021b).

Vibratory pile driving used during construction of the RWEC sea-to-shore transition would create an exposure area for underwater sound pressure levels in excess of the 120 dB re 1 µPa threshold (NMFS 2019) for behavioral harassment from continuous noise sources. Based on sound source modeling conducted to support the Revolution Wind incidental take petition (LGL 2022), vibratory pile-driving noise could theoretically extend outward from the cofferdam site up to 31,955 feet (6.05 miles). The surrounding shorelines of Narragansett Bay would restrict the maximum distance vibratory pile-driving noise could travel, limiting potential exposure to those marine mammal species that are likely to occur within this enclosed embayment. Vibratory pile-driving noise could occur for up to 8 hours per day over a maximum of 56 days: 28 days for installation and 28 days for removal.

HRG surveys would also generate impulsive noise but at a lower intensity than impact pile driving, limiting the duration of exposure. Additionally, as the equipment is mobile, the sound source and marine mammal receptors would be moving in relation to one another, further limiting the duration of exposure. Injury-level effects are therefore unlikely, but exposures exceeding behavioral thresholds could still occur. Revolution Wind estimates that up to 10,779 linear miles of preconstruction HRG surveys would occur over 248 days, averaging approximately 43.5 linear miles of exposure each day at a typical vessel speed of 4 knots (LGL 2022). As discussed under the No Action Alternative, BOEM (2021a) reviewed underwater noise levels produced by the available types of HRG survey equipment and NMFS (2021) concurred with BOEM's determination that the loudest available equipment types would be unlikely to injure or measurably affect the behavior of ESA-listed marine mammals. While individual marine mammals may be exposed to HRG survey noise sufficient to cause behavioral effects, those effects would be temporary in nature and unlikely to cause any perceptible longer-term consequences to individuals or populations.

As discussed above, the Revolution Wind–committed EPMs would effectively minimize injury risks to most marine mammals from instantaneous and cumulative noise exposure. Nighttime pile driving is proposed, but NMFS's ITA would require sufficient demonstration of the effectiveness of proposed monitoring and mitigation protocols in the form of a nighttime pile-driving plan prior to initiating any nighttime pile driving. Initial evaluation of monitoring equipment suggests that combined acoustic and visual monitoring methods can be effective for monitoring in the dark (ThayerMahan 2023). Proposed measures emphasize protection of the critically endangered NARW and concentrate construction within a timing window when this species is least likely to be present. This timing window is not protective for all species, and some impact areas for PTS, as well as behavioral effects, are large enough that the potential for individual exposure cannot be ruled out.

Kusel et al. (2023) modeled sound attenuation distance to hearing injury thresholds for construction-related impact pile driving and developed estimates of the number of marine mammals that could be exposed to potential adverse noise-related effects from the Proposed Action to support MMPA compliance. Hannay and Zykov (2022) similarly modeled the attenuation distance to marine mammal hearing and bodily injury thresholds for UXO detonation. Using habitat-based density modeling results reported by Roberts et al. (2016, 2017, 2018, 2021), LGL (2022) then calculated the take associated with these modeled exposure estimates incorporating other factors, such as proposed mitigation measures and marine mammal group sizes. The take results are summarized in Tables 3.15-9 and 3.15-10. LGL (2022) used a sophisticated exposure model to estimate the number of individuals by species that could be exposed to PTS (i.e., permanent hearing injury), TTS (i.e., a temporary and recoverable loss of hearing sensitivity), and other short-term physiological and behavioral effects from exposure to each source of construction noise (e.g., impact pile driving, vibratory pile driving, UXO detonation). The modeled exposure scenario for each species assumed an aggressive construction schedule of up to three WTG monopiles installed per day for 30 days (90 total) during the highest density month of species occurrence in the area and the remaining 10 WTG monopiles and two OSS monopiles installed during the month with the second-highest density. The exposure scenario for UXOs assumes that thirteen 1,000-pound devices would require detonation within the RWF and RWEC work areas and that the devices are distributed spatially such that the exposure areas would not overlap. Additionally, detonations would be limited to one per day, and the noise would be instantaneous, so there would be no temporal overlap in exposure. As stated, Revolution Wind has determined that all 16 UXOs identified within the RWEC corridor can be avoided; therefore, the values presented in Tables 3.15-9 and 3.15-10 are a useful upper bound for estimating the number of animals potentially exposed if additional devices are discovered. Modeling scenarios assume timing restrictions and the use of a noise attenuation system capable of achieving at least a 10-dB reduction in sound source level. Exposure may be further minimized by other established measures (e.g., pre-start clearance zone monitoring using protected species observers (PSOs) and passive acoustic monitoring (PAM), use of night vision equipment and infrared/thermal imaging technology at night, soft starts, and shutdown procedures). Recent work suggests that the use of infrared technology at night is as effective for detecting marine mammals as daylight visual monitoring (Guazzo et al. 2019; Verfuss et al. 2018). See Appendix F, Table F-1 for a complete list of EPMs.

Source: LGL (2022).

Note: Estimated number of individuals is based on established injury thresholds. Cumulative exposure estimates for impact pile driving are based on exposure ranges that consider animal movement modeling for each species. UXO exposure estimates are based on acoustic ranges.

† Modeled exposure estimates based on a worst-case scenario impact hammer installation schedule of 100 12-meter WTGs and two 15-meter OSS monopiles, with up to three WTGs per day and up to two OSSs per day. Installation scenario assumes use of a noise attenuation system achieving 10-dB effectiveness and seasonal restrictions but does not consider other EPMs or mitigation measures.

‡ Model exposure estimates based on worst-case UXO scenario considering detonation of thirteen 1,000-pound (454-kg) explosives with 10 dB of noise attenuation at locations with non-overlapping spatial or temporal impacts. As described in the

text and based on information available as of February 2023 (Orsted 2023), this is likely an overestimate of impacts from UXO detonation.

Source: Hayes et al. (2021, 2022); LGL (2022).

Note: Estimated number of individuals is based on established TTS and behavioral thresholds. TTS thresholds were used to determine exposure estimates to temporary hearing impairment from UXO detonation, while all other exposure estimates are based on the established behavioral thresholds for intermittent and continuous noise (refer to Table

3.15-5). Based on information available as of February 2023 (Orsted 2023), the effects associated with UXO detonation are likely overestimated here because the analysis assumes detonation of thirteen 1,000-pound (454-kg) explosives with 10 dB of noise attenuation at locations with non-overlapping impacts.

* Group includes both long-finned and short-finned pilot whales. Short-finned pilot whales are considered to be rare within the Lease Area because s preferred habitat is not present.

*This page intentionally left blank.*

As shown in the above tables, LGL (2022) estimates that four species of marine mammals could experience PTS injury from exposure to underwater noise from impact pile-driving or UXO detonation noise under the Proposed Action. Specifically, up to eight humpback whales, 59 harbor porpoise, two gray seals, and four harbor seals could be exposed to PTS impacts from these activities. Multiple individuals from several species are likely to experience short-term TTS or behavioral effects from exposure to several different sources of Project-related noise, including HRG surveys and sea-to-shore transition construction, in addition to UXO detonation and impact pile driving. TTS and behavioral exposures can have an array of adverse effects on marine mammals, even in the absence of overt behavioral responses. For example, a reduction in effective "communication space" caused by auditory masking can make it more difficult to locate companions and maintain social organization (Cholewiak et al. 2018). This can increase physiological stress, leading to impaired immune function and other chronic health problems (Brakes and Dall 2016; Davis et al. 2017; Hatch et al. 2012). These kinds of effects are most associated with long-term changes in the ambient noise environment, specifically from chronic exposure to noise from increasing levels of marine vessel traffic. All construction-related noise sources would cease once construction is completed, and most animals suffering from TTS or stress from auditory masking and behavioral exposure would be expected to recover fully within hours to days. Therefore, for most marine mammal species, exposure to behavioral-level noise effects would constitute a **minor** impact. Certain species, notably NARW, may be more sensitive to behavioral exposure. NARWs employ a specialized feeding strategy that could be sensitive to behavioral disturbance (van der Hoop et al. 2019), and disturbance that results in missed feeding opportunities could have significant effects on fitness (Fortune et al. 2013). Short-term behavioral disturbance could therefore lead to greater than minor impacts on this species. However, the likelihood of this level of effect resulting from Project-related noise exposure and its significance at the individual or population level is currently unknown.

The exposure estimates reported in Tables 3.15-9 and 3.15-10 consider the application of seasonal restrictions and noise attenuation systems (also termed noise abatement systems) with 10-dB attenuation efficacy. Bellmann et al. (2020) found three noise abatement systems to have proven effectiveness and to be offshore suitable: 1) the near-to-pile noise abatement systems – noise mitigation screen; 2) the near-to-pile hydro sound damper; and 3) for a far-from-pile noise abatement system, the single and double big bubble curtain. With the near-to-pile noise abatement systems – noise mitigation screen or the single big bubble curtain, noise reductions of approximately 15 to 17 dB in depths of 82 to 131 feet (25 to 40 meters) could be achieved. The near-to-pile hydro sound damper system, independent of the water depth, demonstrated noise reductions of 10 dB with an optimum system design. The achieved broadband noise reduction with a single or double big bubble curtain was dependent on the technical-constructive system configuration. Based on Bellmann et al. (2020), the noise mitigation system performance of a 10-dB broadband attenuation assumed for the Project is considered achievable with currently available technologies for pile-driving activities. Additional EPMs and other minimization measures that may further limit exposure include establishment and monitoring of pre-start clearance zones using PSOs and PAM use of night vision equipment and infrared/thermal technology during nighttime pile driving, and soft-start and shutdown procedures. These measures would significantly reduce, but not completely avoid, marine mammal exposure to PTS and TTS or behavioral effects. Overall, underwater noise during construction activities would have a **minor** to **moderate** adverse effect on marine mammals, depending on the species.

LGL (2022) did not explicitly consider construction vessel noise in their exposure assessment. In general, vessel noise is unlikely to cause hearing injury in marine mammals because this would require prolonged exposure close to the source (i.e., remaining within 400 feet of a large vessel for 24 hours, per NOAA [2018]). This is an unlikely scenario. For example, an animal swimming at 2.5 miles per hour, the lower end of average swim speeds for the NARW (Baumgartner and Mate 2005), would travel 400 feet in less than 2 minutes. This animal would clear the zone of noise exposure (i.e., the area in which underwater noise may exceed the baseline) around a stationary construction vessel within approximately 4 hours. The potential for PTS is highly unlikely because it would require an animal remaining within 400 feet of a vessel for 24 hours; behavioral effects may occur but would be spatially and temporally limited. The likelihood and duration of exposure would be further reduced when construction vessels are moving. Animals and vessels moving in relation to each other are likely to reduce the duration of exposure to potential behavioral and auditory masking effects. However, certain marine mammals, notably dolphins, exhibit "bow-riding" behavior. Bow or wake riding provides an energetic advantage, allowing dolphins to travel at high speeds while using less energy (Würsig 2009) and becoming more energy efficient at speeds above 7 knots as compared to normal swimming at speeds below 4 knots (Williams et al. 1992). Individuals attracted to moving vessels would experience prolonged noise exposure, presumably above the behavioral effects threshold. However, a significant portion of construction vessel activity would occur at speeds at or below 4 knots (e.g., cable installation, HRG surveys, installation vessel travel between foundation sites).

As stated above, though it has not been definitively proven, logic and available data (e.g., Dunlop et al. 2017; Ellison et al. 2012; Southall et al. 2007) suggest that mobile marine mammals would avoid behavioral disturbances like those resulting from vessel noise, meaning that the duration of exposure to noise from slow-moving or closely clustered and stationary construction vessels would be limited. It is also important to recognize that a substantial portion of construction vessel activity would occur in areas with high existing levels of vessel traffic. As such, construction vessels would contribute to, but may not substantially alter, ambient noise conditions generated by existing large vessel traffic. While some individual marine mammals could experience short-term behavioral and auditory effects from vessel noise exposure, these effects would be short term in duration and unlikely to cause measurable effects at the broader stock or population-level. Therefore, construction vessel noise impacts on marine mammals would likely be **minor** adverse because of the intermittent nature of the impact and potential for avoidance behavior.

Impact pile-driving noise could indirectly affect marine mammals by killing, injuring or temporarily altering the distribution of fish and invertebrate prey (see Sections 3.6 and 3.13). These effects would be limited in extent, short term, and unlikely to measurably affect the amount of prey available to marine mammals across the OCS because 1) the area of effect is small relative to the available habitat; 2) the loss of individuals would likely be insignificant relative to natural mortality rates for planktonic eggs and larvae across the GAA, which can range from 1% to 10% per day or higher (White et al. 2014); and 3) construction timing along with EPMs intended to avoid noise impacts in areas with sensitive species. Therefore, the indirect effects of underwater noise on marine mammals through impacts to prey species would be short term and **negligible** adverse.

Pile driving also produces airborne noise. NMFS has established a behavioral sound pressure level threshold of 90 dB re 1 µPa for harbor seals and 100 dB re 1 µPa for other otariid and phocid pinniped exposure to airborne noise sources like pile driving (NOAA 2018). No equivalent airborne noise behavioral thresholds have been established for other marine mammal species. Harbor and gray seals are the only pinniped species group expected to occur in the RWF and RWEC vicinity. Based on the cylindrical spreading model described on the website Discovery of Sound in the Sea (University of Rhode Island 2021), behavioral effects could be experienced within approximately 500 and 10 feet from impact and vibratory pile-driving locations, respectively. However, because seals would experience behavioral harassment and injury-level exposures to underwater noise at greater distance, behavioral exposure to airborne noise is unlikely to occur as an independent effect. Moreover, marine mammal observers would monitor the affected area for seals and would halt construction if individuals are observed within these limits (refer to Appendix F, Table F-1), further minimizing the risk of seal exposure to airborne noise impacts (Baker et al. 2013; VHB 2023). On this basis, airborne noise effects on seals would be **negligible** adverse because of the established EPMs and likely avoidance response.

Helicopters and fixed-wing aircraft could also be used during Project construction. Aircraft operations could result in temporary behavioral responses, including short surface durations, abrupt dives, and percussive behaviors (i.e., breaching and tail slapping) (Patenaude et al. 2002), but BOEM does not expect that these exposures would result in biologically significant effects on marine mammals. On this basis, noise and disturbance effects on marine mammals from aircraft operations under the Proposed Action are expected to be **minor** adverse because of protective regulations and the temporary nature of the impact.

Overall, noise effects on marine mammals from proposed construction and installation activities are expected to range from **negligible** to **moderate** adverse, depending on the activity. Based on the likelihood of occurrence and extent of impacts, impact pile driving would produce underwater noise impacts with the greatest amount of exposure and the highest potential to cause injury-level effects on marine mammals.

<u>Presence of structures:</u> Effects on marine mammals from installation of WTG and OSS foundations would result from underwater noise impacts related to impact pile driving and noise disturbance from associated vessel activity. These impacts are described in the Noise IPF section. Indirect effects on marine mammals such as reduced availability of forage or prey could also result from impacts on invertebrate and finfish prey species (see Sections 3.6.2.2.1 and 3.13.2.2.1, respectively). While indirect effects to fish and invertebrate prey resources would occur, these impacts are not likely to significantly affect the availability of prey and forage resources for marine mammals because of their broad resource base and the minimal anticipated adverse effect to fish and invertebrates during the construction phase. Therefore, construction and installation of offshore structures would have temporary, **negligible** to **minor** adverse effects on marine mammals. Effects to each marine mammal species would depend on the magnitude and extent of effects on forage and prey availability, the significance of those effects on individual survival and reproductive fitness, and the status and sensitivity of the affected population to those impacts.

<u>Vessel traffic:</u> Construction and monitoring vessels pose a potential collision risk to marine mammals, and the noise and disturbance generated by vessel presence could temporarily displace individual marine mammals from preferred habitats. Based on information provided by Revolution Wind (Tech Environmental 2023), BOEM estimates that Project construction would require up to 1,407 one-way trips by various classes of vessels between the RWF and regional ports in Rhode Island, Massachusetts, Connecticut, New Jersey, Virginia, and Maryland, as well as ports in Europe over the 2-year construction period. This equates to approximately 59 trips per month or 704 trips per year. In addition, approximately

10,755 linear miles of preconstruction HRG surveys are anticipated to support micrositing of the WTG foundations and cable routes. HRG surveys could occur during any month of the year and would require a maximum of 248 total vessel days. The construction vessels used for Project construction are described in Table 3.3.10-3 in the COP and in Section 3.16. Typical large construction vessels used in this type of project range from 325 to 350 feet in length, from 60 to 100 feet in beam, and draft from 16 to 20 feet (Denes et al. 2021).

Large construction vessels and barges would account for an estimated 23% of these one-way trips, with the remainder comprising CTVs and other small support vessels. BOEM developed a representative analysis of construction vessel effects on regional traffic volume by evaluating the potential increase in transits across a set of analysis cross sections relative to baseline levels of vessel traffic. These cross sections were developed by DNV GL Energy USA, Inc. (2020) to support the COP and are shown in Figures 3.15-2 and 3.15-3.

Using the port of origin information provided by Revolution Wind (Tech Environmental 2023), the estimated 704 construction vessel trips per year would cross transects 13-17 when leaving the RWF and could cross several different transects depending on the destination port. This would equate to a 30% increase in vessel transits across these transects. However, the Automatic Identification System (AIS) data used in transect analysis do not include many recreational vessels that lack AIS transponders and commercial fishing vessels that deactivate their transponders when actively fishing. These two vessel classes account for the vast majority of vessel activity. For example, DNV GL Energy USA, Inc. (2020) estimated over 19,000 one-way trips per year by commercial fishing vessels between the RWF and area ports. When these vessel trips are included, Project construction would result in a 3.1% increase in vessel transits per year across transects 13–17. In summary, this assessment indicates that construction vessels would likely increase vessel traffic to some degree, and large vessel traffic would measurably increase during the 2-year construction period. This indicates the potential for increased risk of marine mammal collisions.

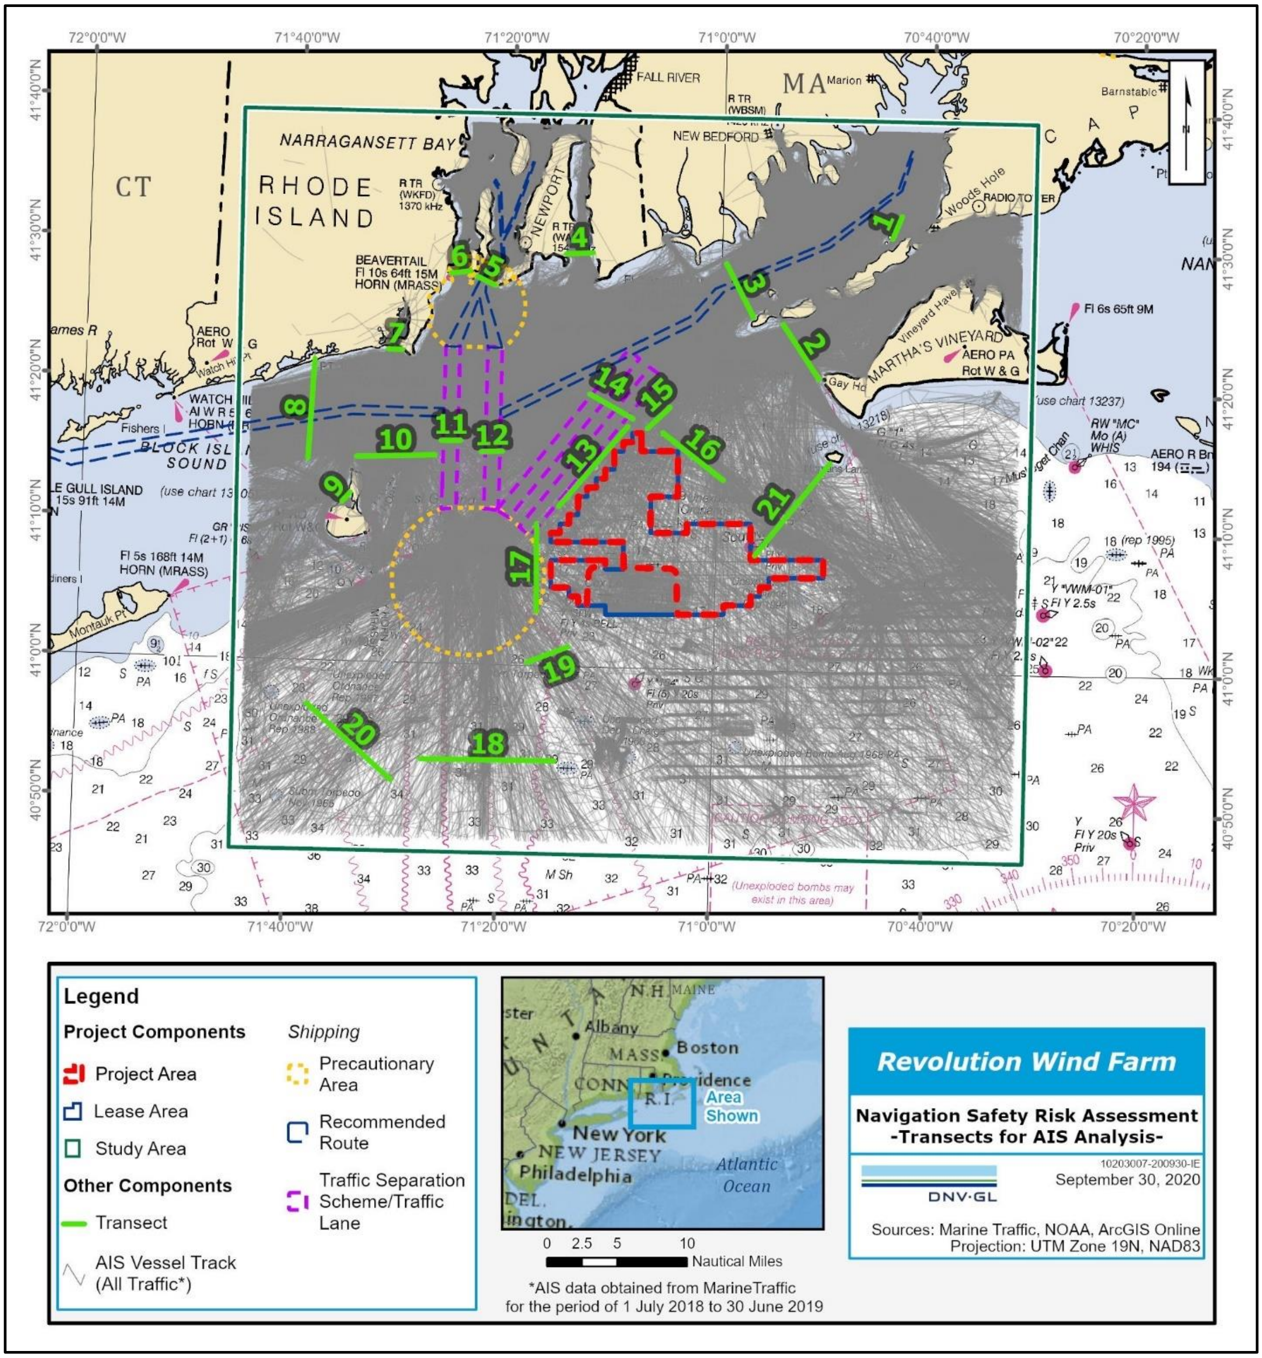

**Figure 3.15-2. Automatic Identification System Vessel Traffic Tracks for July 2018 to June 2019 and Analysis Transects Used for Traffic Pattern Analysis (DNV GL Energy USA, Inc. 2020).**

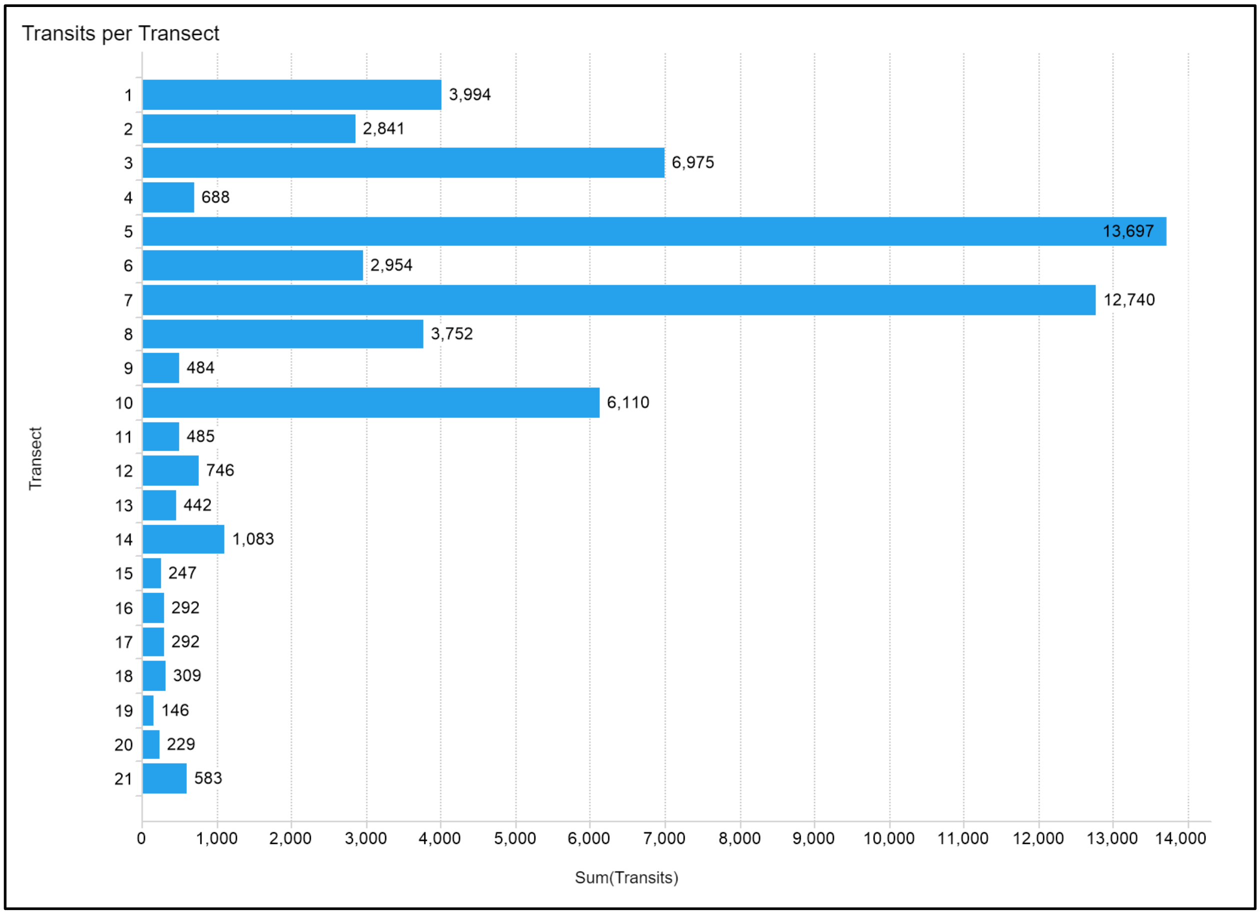

**Figure 3.15-3. Vessel Transits of DNV GL Energy USA, Inc. (2020) Analysis Transects Used for Traffic Pattern Analysis from 2018 to June 2019.**

Vessel collisions are a key source of mortality and serious injury for many marine mammal species (Hayes et al. 2021, 2022; Laist et al. 2001; Rockwood et al. 2017; Schoeman et al. 2020), indicating the importance of protective measures to minimize risks to vulnerable species. If a vessel strike does occur, the impact on marine mammals would range from **minor** to **moderate** adverse for cetaceans and marine mammals other than NARW, with the impact dependent on the number of individuals exposed and population status. Given the imperiled status of NARW, a vessel collision that results in injury or mortality of even a single individual could constitute a **major** impact. However, the applicant has committed to a range of EPMs to avoid vessel collisions with marine mammals (see Appendix F, Table F-1), and these EPMs, plus additional mitigation measures, are expected to result in a discountable risk of vessel strike. These measures include adherence to NOAA guidance for collision avoidance and a combination of others, including approved speed restrictions for all vessels within marine mammal seasonal management areas (SMAs) and dynamic management areas (DMAs). The proposed EPMs have proven effective at avoiding and minimizing collision risk.

BOEM would ensure that all collision avoidance EPMs will be fully implemented. On this basis, BOEM concludes that vessel strikes are unlikely to occur and therefore there is no anticipated effect on marine mammals. In the event of an unanticipated vessel strike of a marine mammal, Project vessels must immediately cease activities until BOEM is able to review the circumstances of the incident and determine what, if any, additional measures are appropriate to ensure compliance with all applicable laws (e.g., ESA, MMPA) and COP approval conditions.

All vessel crews would receive training to ensure that these EPMs are fully implemented for vessels in transit. Once on station, the construction vessels either remain stationary when installing the monopiles and WTG/OSS equipment or move slowly when traveling between foundation locations. Cable laying and HRG survey vessels also move slowly, with typical operational speeds of less than 3 knots and approximately 4 knots, respectively, and present minimal risk of collision-related injury.

The densities of most common species of marine mammals likely to occur in the RWF Lease Area and RWEC route are low based on monthly mean density estimates developed by Roberts et al. (2016, 2017, 2018, 2020, 2021, 2022). Project construction of the maximum-case scenario under the Proposed Action would require an estimated maximum of 1,335 one-way trips for all vessel classes combined over the 2-year construction and installation period. Although this would likely be an increase in vessel traffic in and around the maximum work area of approximately 2% a year, the operational conditions combined with planned EPMs would minimize collision risk during construction and installation. Additional mitigation measures agreed upon through agency consultation would further reduce this risk (see Appendix F for all vessel strike avoidance measures). During periods of low visibility, trained crew would use increased vigilance to avoid marine mammals.

Because vessel strikes are not an anticipated outcome given the relatively low number of vessel trips and EPMs to avoid encountering marine mammals, BOEM concludes vessel strikes are unlikely to occur. Therefore, there is no anticipated effect on marine mammals and collision effects would be **negligible** adverse during Project construction.

The presence of construction vessels and associated noise and disturbance could cause short-term displacement of marine mammals from preferred habitats. Temporary marine mammal displacement from offshore wind energy construction sites have been observed, apparently due to vessel-related disturbance, Long (2017). Habitat use within the affected areas returned to normal after construction was completed, indicating that construction-related displacement effects would be short term in duration. On this basis, vessel displacement effects on marine mammals could range in significance from **minor** to **moderate** adverse depending on the species affected and the biological significance of displacement, recognizing that some portion of these effects is also likely the result of construction noise, as described above.

#### 3.15.2.3.2 Operations and Maintenance and Decommissioning

##### Offshore Activities and Facilities

Anchoring and new cable emplacement/maintenance: Potential anchoring impacts would be similar to the construction phase, but considerably reduced due to fewer anchored vessels. As stated in Section 3.5.2 of the COP, the Project does not anticipate that the IACs, OSS-link cable, and RWEC would require significant maintenance. The cables themselves are unlikely to require repair, but up to 10% of cable protection may need to be replaced over the life of the Project. The IACs, OSS-link cable, and RWEC would be removed from the seafloor during Project decommissioning. Removal of cable protection and extraction of the cable would disturb the seafloor. Vessel anchoring could also be required for specific O&M activities and during Project decommissioning. Effects to marine mammals from cable protection maintenance and vessel anchoring would result primarily from seafloor disturbance, with additional potential effects from underwater noise exposure and collision risk associated with O&M vessel activity. The latter are addressed under their respective IPFs in the following sections. Entanglement risks to marine mammals from vessel anchoring and cable maintenance and decommissioning are not anticipated. Only larger construction and O&M vessels would anchor to the seafloor, no divers would be used, and no lines or rigging are anticipated for cable maintenance. The methods used to remove transmission cables at the end of project life would be specified in the decommissioning plan. Therefore, the likelihood of marine mammal entanglement from this IPF is discountable.

The resulting effects to marine mammals from cable O&M and decommissioning and O&M vessel anchoring would be similar in nature but lesser in scale and magnitude than those resulting from Project construction. As discussed in Section 3.15.2.1, seafloor disturbance effects on marine mammals during Project construction are anticipated to be **negligible** adverse. As such, seafloor disturbance impacts of similar nature but reduced in scale and magnitude from Project O&M and decommissioning would have **negligible** adverse effects on marine mammals.

Noise: Offshore WTGs produce continuous non-impulsive underwater noise during operations, mostly in lower frequency bands below 8 kHz. The low-frequency sounds produced by WTGs are within the range of hearing sensitivity and audible communication frequencies used by many species of marine mammals (NOAA 2018), indicating that this impact mechanism could be a potential source of behavioral and auditory masking effects on marine mammal species.

As discussed under the No Action Alternative, Tougaard et al. (2020) summarized available monitoring data on wind farm operational noise and determined that operating turbines produce underwater sound pressure levels of approximately 110 to 118 dB re 1 µPa at a reference distance of 50 meters, in the 10-Hz to 8-kHz range. More recently, Stober and Thomsen (2021) used monitoring data and modeling to estimate operational noise from 10-MW current generation direct-drive WTGs (i.e., turbines larger than most previously monitored) and concluded that these designs could generate higher operational noise levels than those reported in earlier research.

The potential for behavioral effects on marine mammals can be evaluated by estimating the area exposed to WTG $L_{\mathrm{rms}}$ operational noise above the 120 dB re 1 µPa behavioral harassment threshold for continuous noise sources (NMFS 2019). Applying the practical spreading loss model (spreading coefficient of 15 dB/decade of range) and the general rule of thumb for estimating $L_{\mathrm{rms}}$ from zero-to-peak sound pressure level ($L_{pk}$) (University of Rhode Island 2021),[43] operational ranges of 110 to 118 dB re 1µPa at a reference distance of 164 feet would attenuate below 120 dB re 1 µPa within approximately 35 to 165 feet of each turbine foundation. However, as stated, larger turbines could produce higher operational noise levels that could exceed this threshold at a greater distance.

In addition, it is probable that operational noise would change the ambient sound environment within the Lease Area in ways that could affect habitat suitability. This impact can be evaluated by estimating the area exposed to operational noise above the existing environmental baseline. As discussed under the No Action Alternative, Kraus et al. (2016) measured ambient noise conditions at three locations within and adjacent to the proposed RWF over a 3-year period and identified baseline levels of 102 to 110 dB re 1

[43] An estimate was calculated using the cylindrical spreading loss model (University of Rhode Island 2021).

µPa.[44] Maximum operational noise levels typically occur at higher wind speeds when baseline noise levels are higher due to wave action. Applying the same approach described above, the operational range $L_{rms}$ of 110 and 118 dB re 1 µPa at a reference distance of 50 m would attenuate to the 102 to 110 re 1 µPa baseline within approximately 1,200 feet of each turbine.

Operational noise could interfere with communication and echolocation, reducing feeding efficiency in the areas within a few hundred feet of the monopiles under some conditions. Any such effects would likely be dependent on hearing sensitivity and the ability to adapt to low-intensity changes in the noise environment. Low-frequency cetaceans are more likely to be affected by operational noise as the frequencies generated largely fall within the range of peak hearing sensitivity for these species. These negative impacts could include a variety of long-term physiological and behavioral effects. For example, a reduction in effective “communication space” caused by auditory masking can make it more difficult to find food, locate companions, and maintain social organization (Cholewiak et al. 2018). This can increase physiological stress, leading to impaired immune function and other chronic health problems (Brakes and Dall 2016; Davis et al. 2017; Fortune et al. 2013; Hatch et al. 2012). These kinds of effects are most associated with long-term changes in the ambient noise environment, specifically from chronic exposure to noise from increasing levels of marine vessel traffic. In contrast, mid-frequency cetaceans such as dolphins and sperm whale and high-frequency cetaceans such as harbor porpoise are likely to be less sensitive to the low-frequency sounds generated by operational WTGs because these species are most sensitive to sound at higher frequencies (Johnson 1967; NOAA 2018). Although there can be associated physiological strains, certain species may also be able to acclimatize and adapt to operational noise. For example, while dolphins vocalize in low to middle frequencies, certain species are known to shift vocalization into higher frequency ranges to communicate more effectively in shallow water and adapt to the presence of anthropogenic noise sources (David 2006; Quintana-Rizzo et al. 2006). Therefore, mid-frequency cetaceans are more likely than low-frequency cetaceans to be able to adapt to operational noise effects through responses like shifting their communication frequency range, whereas low-frequency cetaceans may experience interference with communication and echolocation.

On balance, operational noise effects from the RWF are likely to be of low intensity and localized to around each foundation. Jansen and de Jong (2016) and Tougaard et al. (2009) concluded that marine mammals would be able to detect operational noise within a few thousand feet of WTGs, but the effects would have no significant impacts on individual survival, population viability, distribution, or behavior. The findings provided above indicate that operational noise effects would attenuate to ambient levels within a few hundred to a few thousand feet of each foundation, but operational noise would be at levels that could cause behavioral reactions in marine mammals within 120 feet of each turbine. There is the potential for a reduction in effective communication space within the wind farm environment for marine mammals that communicate primarily in frequency bands below 8 kHz (i.e., low-frequency cetaceans). This localized, long-term impact would constitute a **moderate** adverse effect on marine mammals belonging to the low-frequency cetacean hearing group. Operational noise effects on marine mammals in other hearing groups would be **negligible** to **minor** adverse because operational noise overlaps the sound frequencies used for hearing and communication by these species to a lesser degree. It is unknown if operational noise would contribute to displacement effects to marine mammals.

[44] These are 50th and 90th percentile values for monitoring locations RI-1, RI-2, and RI-3, as reported by Kraus et al. (2016).

O&M HRG surveys would also generate impulsive and non-impulsive noise during Project operations. Up to 1,062 linear miles of O&M HRG surveys may be conducted in the RWF and RWEC corridor every year for up to 4 years following Project construction (LGL 2022). As noted above in Section 3.15.2.2.1, BOEM (2021a) determined, and NMFS concurred (NMFS 2021), that HRG survey activities would be unlikely to injure or measurably affect the behavior of ESA-listed marine mammals. This finding can also be applied to non-listed marine mammal species. LGL (2022) estimated the exposure of marine mammal species to 4 years of postconstruction HRG surveys (Table 3.15-11). Overall, noise generated by O&M HRG surveys would likely have a **minor** adverse effect on marine mammals because of the limited exposure and likelihood of full recovery within hours to days.

O&M vessels would also generate periodic, short-term underwater noise impacts with the potential to affect marine mammals. Revolution Wind (Tech Environmental 2023) has estimated that Project O&M would involve up to four CTV and two SOV trips per month for wind farm O&M, or 2,280 vessel trips over the life of the Project. These trips would originate either from an O&M facility located either in Montauk, New York, or Davisville, Rhode Island. One or more CTVs ranging from 62 to 95 feet in length would be purpose built to service the RWF over the life of the Project. SOVs are larger mobile work platforms, on the order of 215 to 305 feet long and 60 feet in beam, equipped with dynamic positioning systems used for more extensive, multi-day maintenance activities (Ulstein 2021). Larger vessels similar to those used for construction could be required for unplanned maintenance, such as repairing scour protection or damaged WTGs. Those activities would occur on an as-needed basis. Additional vessel trips would be required over the life of the Project for seafloor surveys and subsurface inspections. A minimum of three postconstruction seafloor bathymetry surveys would be conducted to assess foundation scour and correct if needed. Project fishery monitoring and benthic habitat monitoring surveys would also be conducted seasonally. Vessels used would be similar to those used for preconstruction HRG surveys.

**Table 3.15-11. Estimated Number of Marine Mammals Experiencing Behavioral Effects from Postconstruction High-Resolution Geophysical Survey Activities**

| Functional Hearing Group | Species | Estimated Number of Individuals Exposed to Behavioral Level Noise Effects Postconstruction HRG Surveys (4 years total) | NMFS Stock Abundance | Number of Individuals Exposed as Percent of Stock Abundance |
|---|---|---|---|---|
| LFC | Blue whale* | 4 | 402 | 1.0% |
| | Fin whale* | 64 | 6,802 | 0.9% |
| | Humpback whale | 184 | 1,396 | 13.2% |
| | Minke whale | 40 | 21,968 | 0.2% |
| | North Atlantic right whale* | 12 | 338 | 3.6% |
| | Sei whale* | 8 | 6,292 | 0.1% |
| MFC | Atlantic spotted dolphin | 116 | 39,921 | 0.3% |
| | Atlantic white-sided dolphin | 112 | 93,233 | 0.1% |
| | Bottlenose dolphin | 260 | 62,851 | 0.4% |

| Functional Hearing Group | Species | Estimated Number of Individuals Exposed to Behavioral Level Noise Effects Postconstruction HRG Surveys (4 years total) | NMFS Stock Abundance | Number of Individuals Exposed as Percent of Stock Abundance |
|---|---|---|---|---|
| | Common dolphin | 7,284 | 172,974 | 4.2% |
| | Pilot whales† | 36 | 68,139 | 0.1% |
| | Risso's dolphin | 24 | 35,215 | 0.1% |
| | Sperm whale* | 8 | 4,349 | 0.1% |
| HFC | Harbor porpoise | 132 | 95,543 | 0.2% |
| Phocid pinnipeds | Gray seal | 196 | 27,300 | 0.7% |
| | Harbor seal | 436 | 61,336 | 0.7% |

Source: Hayes et al. (2021, 2022); LGL (2022).

* ESA-listed species.

† Group includes both long-finned and short-finned pilot whales. Short-finned pilot whales are considered to be rare within the Lease Area because preferred habitat is not present.

Noise levels generated by the CTVs are expected to have source levels of approximately 160 dB re 1 µPa-m, based on observed noise levels generated by working commercial vessels of similar size and class to the CTVs (Kipple and Gabriele 2003; Takahashi et al. 2019). The SOV would produce similar noise levels to those described for construction vessels by Denes et al. (2021), with an approximate $L_{rms}$ source level of 170 dB re 1 µPa-m. BOEM anticipates that underwater noise generated by CTVs and monitoring vessels would overlap the hearing range and would be audible to most marine mammal species potentially present near the Lease Area. However, the noise levels generated by these smaller Project vessels are below the hearing injury threshold of marine mammals and animals are expected to only have short, transient exposures; therefore, vessel noise from Project monitoring activities is not expected to result in injury-level effects. Noise levels generated by the larger SOVs would be similar to those described in Section 3.15.2.2.1 for Project construction vessels and would result in short-term **minor** adverse noise effects that would occur periodically throughout the life of the Project.

Vessel traffic associated with EPM monitoring could result in brief behavioral responses that would be expected to dissipate once the vessel or the individual has left the area. BOEM expects that these brief responses of individuals to passing vessels would be infrequent. Therefore, noise effects from vessels associated with monitoring efforts would result in **negligible** adverse impacts to marine mammals.

The associated disturbance from decommissioning would be similar to that described above for construction (see Section 3.15.2.2.1), with the exception that pile driving would not be required. While specific decommissioning equipment and methods have not yet been proposed, it is reasonable to assume that the associated impacts would be comparable in magnitude to those resulting from Project construction. One important exception is that impact pile driving would not be required; therefore, underwater noise impacts from decommissioning would be less intense and extensive than those from construction. The monopiles would be cut below the bed surface for removal using a cable saw or abrasive waterjet. Noise levels produced by this type of cutting equipment are generally indistinguishable from engine noise generated by the associated construction vessel (Pangerc et al. 2016). On this basis, short-term effects on marine mammals from decommissioning would be **negligible** adverse because of the limited exposure to noise during decommissioning activities.

Presence of structures: The presence of RWF monopile foundations over the life of the Project would change the offshore environment, and their presence could affect marine mammal behavior; however, the likelihood and significance of these effects are difficult to determine. As discussed in the No Action Alternative, Long (2017) compiled a statistical study of seal and cetacean (including porpoises and baleen whales) behavior in and around Scottish wave energy converter facilities. The study found evidence of displacement during construction, but habitat use appeared to return to previous levels once construction was complete. No observable long-term displacement effects on seals, porpoises, dolphins, or large whales from wave energy converter operations were observed, but these findings may not be applicable to offshore wind structures. Long (2017) also cautioned that observational evidence was limited for certain species and further research would be required to draw a definitive conclusion about operational effects. Delefosse et al. (2017) reviewed marine mammal sighting data around oil and gas structures in the North Sea and found no clear evidence of species attraction or displacement. Other studies have documented apparent changes in marine mammal behavior around wind energy facilities. Some research has suggested that wind farm operations may lead to long-term displacement of species such as harbor porpoise, but the evidence is mixed, and observed changes in abundance could be more indicative of general population trends than an actual wind farm effect (Nabe-Nielsen et al. 2011; Tielmann and Carstensen 2012; Vallejo et al. 2017).

Offshore wind structures are unlikely to interfere with marine mammal movement. The up to 102 RWF monopile foundations proposed under Alternative B would be placed in a grid-like pattern with spacing of approximately 1.0 (0.9 to 1.1) nm between turbines. Based on documented adult lengths (Wynne and Schwartz 1999), the largest NARW (59 feet), fin whale (79 feet), sei whale (59 feet), and sperm whale (59 feet) would fit end-to-end between two foundations spaced at 1 nm 100 times over. This simple assessment of spacing relative to animal size indicates that the physical presence of the monopile foundations is unlikely to pose a barrier to the movement of large marine mammals, and even less likely to impede the movement of smaller marine mammals.

Hydrodynamic and reef effects could theoretically cause indirect effects on marine mammals by changing the distribution and abundance of preferred prey and forage species. Monopile foundations and scour protection would generate an artificial reef effect as surfaces are colonized by habitat-forming organisms (Degraer et al. 2020), likely leading to enhanced biological productivity and increased abundance and concentration of fish and invertebrate resources within and around the Lease Area (Hutchison et al. 2020). This could alter predator-prey interactions with uncertain and potentially beneficial or adverse effects on marine mammals. For example, fish predators like seals and porpoises could benefit from increased biological productivity and abundant concentrations of prey generated by the reef effect (e.g., Russel et al. 2014). Conversely, increased fish biomass around the structures could attract commercial and recreational fishing activity, creating an elevated risk of injury or death from gear entanglement (Moore and van der Hoop 2012). Fisheries interactions are a known source of negative impacts on marine mammals, with estimated global mortality across species exceeding hundreds of thousands of individuals each year (Read et al. 2006; Reeves et al. 2013; Thomas et al. 2016). Entanglement in fishing gear has been identified as one of the leading causes of mortality in NARW and could be a limiting factor in the species' recovery (Knowlton et al. 2012). Project EPMs include inspection and removal of marine debris from foundations (see Table F-1 in Appendix F). This would help to reduce the minimal risk of entanglement in debris caught on structures and provide a mechanism for removing potentially harmful derelict gear from the marine environment.

The RWF would also cause hydrodynamic effects that could influence the distribution and abundance of fish and planktonic prey resources (van Berkel et al. 2020). Offshore wind farms can influence hydrodynamic conditions through two mechanisms: turbulent effects on mixing and stratification patterns caused by current flow around structures in the water column, and changes in surface wave and current patterns caused by wind field effects (i.e., the extraction of wind energy from the atmosphere) (Johnson et al. 2021; van Berkel et al. 2020). Turbulence in the water column created by structure wakes could lead to localized changes in circulation and stratification patterns, with potential implications for primary and secondary productivity and fish distribution. These localized effects would likely be limited to a few hundred to a few thousand feet downcurrent of each foundation.

In contrast, the combined effects of a WTG array on the wind field and surface waves are typically more extensive (Johnson et al. 2021; van Berkel et al. 2020). A growing body of research has demonstrated that offshore wind farms could have observable effects on oceanographic conditions up to tens of miles downfield from wind farm sites (e.g., Christiansen et al. 2022; Daewel et al. n.d. [2023]; Dorell et al. 2022; Floeter et al. 2022; Raghukumar et al. 2022), although the extent of these effects and the resulting significance on biological processes are likely to vary considerably between different oceanographic environments (van Berkel et al. 2020). Van Berkel et al. (2020) and Schultze et al. (2020) note that environments characterized by strong seasonal stratification, such as the Mid-Atlantic Bight, are likely to be less sensitive to changes and disruptions to oceanographic processes from wind farm effects. In addition, atmospheric effects are influenced by WTG design. Golbazi et al. (2022) demonstrated that the surface effects of wind wakes from 10 to 15 MW WTGs, the size range being considered for development in the region, were appreciably less extensive than those produced by the smaller turbine designs currently employed in Europe (Akhtar et al. 2022; Christiansen et al. 2022; Daewel et al. 2022). Broadly speaking, the atmospheric effects of wind farms appear to decrease as WTG hub height above the sea surface increases. Collectively, these findings indicate that planned future wind farm development on the Mid-Atlantic OCS are unlikely to produce hydrodynamic effects on the order of those associated with European wind farm development in the southern North Sea (e.g., Christiansen et al. 2022; Daewel et al. n.d. [2023]; Dorell et al. 2022).

As discussed in Section 3.6.2.5.2, hydrodynamic effects from RWF development could lead to changes in the dispersal of planktonic eggs and larvae. This suggests that marine mammal species that rely on planktonic prey resources, like NARW, may experience shifts in the availability of preferred resources due to hydrodynamic effects. NARW typically depends on the formation of compressed concentrations of their preferred copepod prey organisms for energy efficient feeding (Baumgartner and Mate 2003; Baumgartner et al. 2017). These compressed concentrations most commonly form during periods of strong stratification and low mixing. Turbulent mixing around wind farm wakes could theoretically scatter these tight copepod concentrations. However, NARWs are most commonly present in southern New England waters during winter months when the water column is well mixed and planktonic organisms are more widely dispersed. NARW may tolerate inefficient feeding during winter to maintain nutritional intake. For example, White and Veit (2020) recently described an association between sea duck distribution and abundant patches of Gammarid amphipods on the western edge of Nantucket Shoals, where NARWs are also found, suggesting that NARW may prey on these amphipods as well in this area. Turbulent mixing effects are likely to be less evident during the well-mixed conditions that predominate during winter.

BOEM conducted a hydrodynamic modeling study to evaluate how wind farm presence could affect the seasonal stratification patterns that contribute to the formation and persistence of the Mid-Atlantic cold pool (Johnson et al. 2021). The findings of this hydrodynamic study and their implications for invertebrates, finfish, and primary and secondary productivity are discussed in detail in Sections 3.6.2.3.2 and 3.13.2.2.2. In summary, the RWF and surroundings are characterized by strong seasonal stratification occurring in summer and early fall, which is expected to limit measurable hydrodynamic effects within the wind farm to within 600 to 1,300 feet downcurrent of each monopile (van Berkel et al. 2020). During winter months, the water column is well mixed, and turbulent mixing effects are likely to be less evident. Localized turbulence and upwelling effects around the monopiles are likely to transport nutrients into the surface layer, potentially increasing primary and secondary productivity. That increased productivity could be partially offset by the formation of abundant colonies of filter feeders on the monopile foundations. As discussed in the No Action Alternative, hydrodynamic effects on wind field and wave energy could influence surface currents at scales on the order of miles to tens of miles, potentially altering the distribution of planktonic organisms (Johnson et al. 2021).

These findings suggest that hydrodynamic effects are unlikely to affect the abundance and availability of zooplankton prey sufficiently to have a measurable effect at the population level, but could alter the distribution of prey at scales ranging from miles to tens of miles. In the absence of other factors, localized impacts on zooplankton and fish abundance and distribution on the scale described are not likely to be biologically significant for marine mammals when considered relative to the broader oceanographic factors that determine primary and secondary productivity in the region and seasonal and interannual variability. However, those changes could become significant if they lead to increased interaction with fisheries or vessel traffic. The likelihood of this type of effect, and the resulting effects to marine mammals, are difficult to predict and therefore unknown.

In summary, long-term reef and hydrodynamic effects resulting from the Proposed Action could result in **minor** beneficial effects on fish-eating marine mammals such as dolphins and seals that benefit from increased prey abundance around the structures. These effects could cause localized changes to prey distribution but do not suggest a notable change in prey availability. It is unclear if these have a significant impact to the ability for marine mammals to feed. Long-term reef and hydrodynamic effects could result in negligible adverse effects on marine mammals that forage on plankton and forage fish. Habitat conditions would be expected to revert back to pre-Project conditions when the Project is decommissioned, or similar conditions within the limits determined by climate change and other ongoing environmental trends. BOEM concludes that the physical presence of RWF monopile foundations would pose a negligible adverse risk of displacement effects on marine mammals by posing a barrier to movement. However, this determination does not consider the potential effects of operational noise, which are localized, long-term impacts and would constitute a **minor** to **moderate** adverse effect on marine mammals belonging to the low-frequency cetacean hearing group. Operational noise effects on marine mammals in other hearing groups would be negligible to minor adverse because the degree to which operational noise overlaps the range of frequencies used for hearing and communication is more limited.

Reef and hydrodynamic effects from the presence of structures would cease when the Project is decommissioned and structures are removed from the environment. Marine mammal prey and forage organisms would redistribute in response to the new baseline ecological and oceanographic conditions. Therefore, the effects of the presence of structures on marine mammals following decommissioning would be **negligible** adverse.

Vessel traffic: Revolution Wind (Tech Environmental 2023) has estimated that Project O&M would involve up to one CTV trip each week and one SOV trip every other week to the RWF over the life of the Project. CTV trips shared between RWF and other offshore energy projects and daughter craft activity could account for an additional 23 vessel trips per year. In total, Project O&M would require an estimated 3,030 vessel trips over the life of the Project. These trips would originate from an O&M facility located either in Montauk, New York, or Davisville, Rhode Island. One or more CTVs ranging from 62 to 95 feet in length would be purpose built to service the RWF over the life of the Project. SOVs are larger mobile work platforms, on the order of 215 to 305 feet long and 60 feet in beam, equipped with dynamic positioning systems used for more extensive, multi-day maintenance activities (Ulstein 2021). Larger vessels similar to those used for construction could be required for unplanned maintenance, such as repairing scour protection or replacing damaged WTGs. Those activities would occur on an as-needed basis. Additional vessel trips would be required over the life of the Project for seafloor surveys and subsurface inspections. A minimum of three postconstruction seafloor bathymetry surveys would be conducted to assess foundation scour and correct if needed. Project fishery monitoring and benthic habitat monitoring surveys would also be conducted annually. Vessels used would be similar to those used for the HRG surveys conducted prior to and during Project construction.

In general, O&M-related vessel activities would represent a small increase in regional vessel traffic compared to existing conditions. Project O&M could involve up to 10 one-way vessel trips between the RWF and O&M facility or other area ports each month. By comparison, hundreds of large vessels and thousands of smaller vessels, many of the latter comparable in size to the CTV, travel through the areas between the wind farm and proposed O&M facility locations on a monthly basis (Section 3.15.2.2.1). O&M vessel use would therefore represent a minimal increase in regional vessel traffic over the life of the facility.

As detailed in Appendix F, all survey vessels would comply with speed restrictions and other minimization measures to minimize risk of collision with marine mammals, making the risk of vessel strikes from survey vessels unlikely. This conclusion is informed by estimated marine mammal densities within the Lease Area and RWEC corridor (Roberts et al. 2016, 2017, 2018, 2020, 2021, 2022), which are generally low in comparison to those in core habitats used by each species. Although species-specific density estimates vary by season, indicating that collision risk would also vary, the vessel strike avoidance measures are designed adaptively to respond to changing conditions as needed to minimize collision risk. Operational conditions combined with planned EPMs (see Appendix F for all vessel strike avoidance measures) would minimize collision risk during construction and installation, O&M, and decommissioning. During periods of low visibility, trained crew would use increased vigilance to avoid marine mammals, including night vision devices and infrared imaging (LGL 2022). BOEM concludes vessel strikes are unlikely to occur and therefore there is no anticipated effect on marine mammals. In the event of an unanticipated vessel strike of a marine mammal, project vessels must immediately cease activities until BOEM is able to review the circumstances of the incident and determine what, if any, additional measures are appropriate to ensure compliance with all applicable laws (e.g., ESA, MMPA) and COP approval conditions. Overall, effects of vessel traffic on marine mammals from Project O&M and decommissioning would be **negligible** to **minor** adverse because of limited risk exposure and anticipated EPM effectiveness.

#### 3.15.2.3.3 Cumulative Impacts

This section discloses potential impacts to marine mammals associated with future offshore wind development, including the Proposed Action. The cumulative impact analysis for the Proposed Action includes Alternative B, other planned non-offshore wind activities, as well as activities associated with constructed or approved offshore wind projects. Cumulative impacts to marine mammals under the Proposed Action presented herein would be incremental to and would compound the impacts of baseline conditions on each marine mammal population considered in this EIS (see Table 3.15-2).

##### Offshore Activities and Facilities

<u>Anchoring and new cable emplacement/maintenance:</u> The Proposed Action would result in localized, temporary, **negligible** adverse impacts to marine mammals through an estimated 7,213 acres of anchoring and cabling-related seafloor disturbance and associated increased suspended sedimentation within the GAA. BOEM estimates a cumulative total of 105,390 acres of cabling seafloor disturbance and 11,631 acres of anchoring disturbance for the Proposed Action plus all other future offshore wind projects in the GAA. No population-level effects on marine mammals are expected from reduced water quality. However, there could be temporary displacement of marine mammals from preferred habitats, especially during construction activities, due to increased vessel activity. Vessel anchoring and cable emplacement during construction and installation, O&M, and decommissioning are not anticipated to involve equipment, lines, or rigging that could pose a potential entanglement risk to marine mammals. Therefore, the Proposed Action combined with past, present, and reasonably foreseeable activities would result in **negligible** to **minor** adverse cumulative effects on marine mammals.

<u>Climate change:</u> Global climate change is altering water temperatures, circulation patterns, and oceanic chemistry at global scales. Several marine species, including fish, invertebrates, and zooplankton—prey resources for marine mammals—have shifted northward in distribution over the past several decades (NOAA 2021b). Ocean acidification, also a function of climate change, has negatively affected some zooplankton species (PMEL 2020). Marine mammals are modifying their behavior and distribution in response to these broader observed changes (Davis et al. 2017, 2020; Hayes et al. 2020, 2021, 2022). These trends are expected to continue, with complex and potentially adverse consequences for many marine mammal species. The Proposed Action in combination with existing and planned future actions would result in the development of a network of artificial reefs distributed across the GAA. The biological hotspots created by these artificial reefs are expected to influence fish and invertebrate community structure at local scales and could also influence the ability of certain fish and invertebrate species to shift and expand their ranges in response to climate change. This could in turn result in cumulative effects on marine mammals that could be beneficial or adverse depending on a number of complex factors. The nature and potential significance of these effects to marine mammals are unknown but are likely to range from **minor** to **moderate** adverse. Effects to specific marine mammal species, such as NARW, would depend on how climate change affects habitat suitability and forage availability, the status and resilience of affected populations, and the ability to adapt to these impacts.

Noise: BOEM estimates that a cumulative total of 3,190 offshore WTGs and OSS foundations would be developed in the GAA for marine mammals between 2022 and 2030.While the number and distribution of potential UXO encounters is not currently known, it is likely that a least some UXO detonations would be required. Device size is also not currently known but would likely fall within a similar range of impacts to those described for construction of the Proposed Action.

Section 3.15.1.1 provides an overview of potential concurrent construction activities in the GAA. Each action would generate underwater noise of similar type and intensity as the Proposed Action, scaled in extent to the size of each facility. Each future project would be anticipated to result in adverse effects on individual marine mammals, up to and including PTS, and TTS, auditory masking and behavioral impacts. Construction noise would also contribute to short-term displacement effects, as described above.

All future actions would be subject to the same independent NEPA analysis and regulatory approvals as the Proposed Action. BOEM would require all projects to incorporate the same types of EPMs included in the Proposed Action to avoid and minimize harmful noise effects. While these measures would avoid and minimize impacts to marine mammals to the greatest extent practicable, some unavoidable impacts on individuals are likely to occur. The impacts of each project would result in **minor** to **moderate** adverse effects on marine mammals. Cumulative noise effects on marine mammal species would depend on the number of individual animals exposed to injury and behavioral level noise effects, the significance of those effects to survival and reproductive success, and the status of the affected population. BOEM anticipates that future MMPA approvals would consider the known status of individual marine mammal stocks and populations, indirectly incorporating the potential combined effects of future projects. Therefore, BOEM concludes that the cumulative effects of construction noise on marine mammals would be **moderate** adverse because of the potential for PTS, TTS, and behavioral impacts during construction activities. NARW could be an exception to this determination because of its perilous population status. Hearing-related injury to even one individual that results in reduced reproductive fitness could contribute to ongoing downward trends in population viability. Should such impacts occur, they could constitute a greater than moderate adverse impact on this species. However, the EPMs proposed for this project should effectively avoid this level of impact.

As discussed in Sections 3.15.1.1 and 3.15.2.2, operational noise from offshore wind turbines is expected to be limited in intensity and extent. Operational noise exceeding the 120 dB re 1 µPa behavioral harassment threshold would be limited to within approximately 35 to 165 feet of each turbine (per NOAA 2018), although detectable noise above ambient levels could extend up to approximately 1,200 feet. The Proposed Action combined with all existing and planned future actions would place over 3,000 noise-generating WTG foundations in the RI/MA and MA WEAs. These structures would contribute to and potentially increase ambient noise within each WEA, albeit at levels generally not associated with adverse effects on marine mammals. However, the 120 dB re 1 µPa threshold may not adequately represent the potential for adverse effects of chronic noise exposure (e.g., Cholewiak et al. 2018; Hatch et al. 2012; Jensen et al. 2009; Putland et al. 2017). While the potential for broader effects is unclear, BOEM concludes that the cumulative effects of low-level operational noise could raise to the level of **minor** adverse for certain marine mammal species.

Presence of structures: BOEM estimates a cumulative total of up to 3,190 offshore WTGs and OSS foundations in the GAA for marine mammals between 2022 and 2030. This total comprises foundations from the Proposed Action and up to 3,088 foundations associated with existing (BIWF) and planned state and federal offshore wind energy projects on the OCS between North Carolina and Maine (see Appendix E3, Table E3-1).

Project construction is likely to result in short-term displacement effects on marine mammals from the areas affected by disturbance from vessel activity, foundation installation, HRG surveys, and related activities. Several projects are expected to be constructed concurrently, potentially resulting in individual marine mammals being exposed to multiple episodes of habitat displacement. BOEM anticipates that the construction schedules for future wind projects would employ the same types of timing restrictions to protect NARW as those included in the Proposed Action, with modifications as needed to adapt to ongoing shifts in the seasonal distribution of this species (e.g., Davis et al. 2017, 2020). However, timing restrictions for NARW would not be protective for all marine mammal species. It is anticipated that future wind projects would also employ a similar range of EPMs to avoid and minimize impacts to marine mammals, but some level of short-term displacement is likely to occur, and some individual animals are likely to be exposed to multiple episodes of displacement. The significance of these potential impacts is unclear, but when all protective measures are considered, cumulative effects are likely to range from **negligible** to **moderate** adverse. Impacts to each marine mammal species, such as NARW, are uncertain and would depend on several factors, including species-specific displacement effects, the nature and extent of effects to forage resources, and, the status and sensitivity of the affected population to effects to individuals.

BOEM anticipates that future wind projects within the RI/MA WEA would be constructed using 1 × 1–nm grid spacing, as does the Proposed Action. Foundations spaced at 1 × 1 nm are unlikely to pose a barrier to movement for even the largest marine mammal species. However, the broadscale development of offshore energy structures would introduce an extended network of biologically productive artificial reefs, most generating low levels of non-impulsive sound that are detectable to marine mammals within a few hundred feet. While the individual effects of each turbine would be **minor** adverse, the broader implications of these habitat changes for marine mammals are unclear. Displacement effects that result in increased interactions between vulnerable populations of marine mammals and commercial shipping and/or fishing activity could have significant long-term cumulative effects. Given these uncertainties, the potential for displacement and level of effects is unknown, but there is currently no basis to conclude that these impacts would result in greater than minor adverse long-term effects on any species.

The abundance of fish and invertebrate prey resources created by the artificial reef effect are likely to attract predatory marine mammals, particularly seals (e.g., Russel et al. 2014) and potentially dolphins and porpoises. Increased fish biomass around the structures could attract commercial and recreational fishing activity, leading to increased interactions between humans and marine mammals. BOEM anticipates that future projects would perform regular inspections to identify and remove derelict fishing gear and other marine debris from offshore structures, reducing associated risks to marine mammals.

The new wind energy structures would also cause hydrodynamic effects. Marine mammal species that rely on planktonic prey resources, like NARW, may experience shifts in the availability of preferred resources due to these hydrodynamic effects. NARW typically depends on the formation of thin vertically compressed layers of copepods to efficiently feed (Baumgartner and Mate 2003; Baumgartner et al. 2017). However, during the winter months, when they are primarily present in southern New England waters and the water column is well mixed, they may tolerate inefficient feeding simply to gain some nutrition. For example, White and Veit (2020) recently described an association between sea duck distribution and abundant patches of Gammarid amphipods on the western edge of Nantucket Shoals, suggesting that right whales also present there may prey on these amphipods as well. Thus, the potential hydrodynamic effects discussed in the subsequent paragraphs may influence the availability of already limited prey resources for NARW.

A growing body of research has demonstrated that offshore wind farms could have observable effects on oceanographic conditions up to tens of miles downfield from wind farm sites (e.g., Christiansen et al. 2022; Daewel et al. n.d. [2023]; Dorell et al. 2022; Floeter et al. 2022; Raghukumar et al. 2022), although the extent of these effects and resulting significance on biological processes are likely to vary considerably between different oceanographic environments (van Berkel et al. 2020). In addition, atmospheric effects are influenced by WTG design. Golbazi et al. (2022) demonstrated that the surface effects of wind wakes from 10 to 15 MW WTGs, the size range being considered for development in the region, were appreciably less extensive than those produced by the smaller turbine designs currently employed in Europe (Akhtar et al. 2022; Christiansen et al. 2022; Daewel et al. 2022). Broadly speaking, the atmospheric effects of wind farms appear to decrease as WTG hub height above the sea surface increases. Collectively, these findings indicate that planned future wind farm development on the Mid-Atlantic OCS are unlikely to produce hydrodynamic effects on the order of those associated with European wind farm development in the southern North Sea (e.g., Christiansen et al. 2022; Daewel et al. n.d. [2023]; Dorell et al. 2022).

As discussed in the previous section, the Proposed Action is not anticipated to result in additive hydrodynamic effects. However, broader scale development of contiguous projects could have more extensive effects. For example, Afsharian et al. (2020) modeled the potential effects from installation of over 400 offshore wind turbines in Lake Erie and determined that their cumulative effect on wind energy could disrupt circulation patterns and affect seasonal stratification and water temperatures over broad scales. However, these findings may not be applicable to the open ocean where circulation patterns are strongly influenced by tides and ocean currents.

At present, currently available information suggests that hydrodynamic effects of foundation structures are likely to be localized and not additive when spaced at 1 × 1 nm in environments with strong seasonal stratification (van Berkel et al. 2020). Recent modeling of hydrodynamic effects suggests that surface currents could be affected by the presence of multiple wind farms potentially impacting the distribution of larvae (Johnson et al. 2021). There is insufficient information to determine if this conclusion is valid for broader scale development at the levels planned within the GAA. Therefore, at this time, there is no basis to conclude that the cumulative hydrodynamic impacts of Proposed Action in combination with planned future actions would have a measurable effect on marine mammals and their prey and forage species.

In summary, the cumulative effects of long-term habitat alteration and hydrodynamic impacts on marine mammals are unclear, could be beneficial or adverse, and could range from **negligible** to **moderate** adverse. Effects to specific species, such as NARW, would depend on several factors including the nature and distribution of changes in forage availability, resulting effects on individual survival and reproductive fitness, and the status and sensitivity of the affected population to these impacts. Although the type and magnitude of effect from displacement and shifts in prey resources due to the presence of structures are largely unknown, the possibility of changes in distribution relative to commercial fishing activity and increased interaction with fishing gear poses the potential for increased risk of entanglement. Should such changes occur, increased risk of entanglement would constitute a **minor** to **moderate** adverse effect on marine mammals, because this stressor is a documented source of injury and mortality. Effects to each marine mammal species would depend on the number of individual animals exposed to entanglement effects, the nature of the impact (i.e., injury or mortality), and the status and sensitivity of the affected population to these impacts. In the case of NARW, the potential for increased exposure to entanglement could pose a significant risk as injury or mortality that removes even one juvenile or reproductive age individual from the population would constitute a greater than moderate effect. It is important to stress that the likelihood of this level of effect is unclear because it is not known if the presence of structures would displace NARW and whether displacement would lead to increased fishing gear exposure. These potential long-term impacts would persist until decommissioning is complete and structures are removed. EPMs would help to offset the potential impact of entanglement within derelict fishing gear or marine debris.

Vessel traffic: BOEM estimates that, cumulatively, up to 262 construction vessels could be active within the GAA between 2022 and 2030. As discussed above for Project construction, the majority of vessel operations would be expected to occur at speeds of less than 10 knots. In addition, BOEM anticipates that future projects would adhere to mandatory and voluntary vessel speed restrictions in posted DMAs and SMAs and would implement EPMs similar to those described for the Proposed Action (see Appendix F, Table F-1) to avoid marine mammal collisions. BOEM has concluded that these measures would effectively avoid all but minor adverse impacts on sensitive species such as NARW and minimize risk of vessel collisions to other marine mammal species. Therefore, the cumulative effects of increased vessel traffic on marine mammals would range from **negligible** to **moderate** adverse.

#### 3.15.2.3.4 Conclusions

Impacts of Alternative B, the Proposed Action. Project construction would primarily result in noise that would disturb marine mammals and potentially result in permanent impacts (i.e., PTS). EPMs would minimize noise exposure such that any PTS of NARWs would be avoided and, for all marine mammals, the severity of any behavioral responses would be minimized. Therefore, the incremental impact of the Proposed Action when compared to the No Action Alternative would be minor for NARWs from construction given the likely outcome of noise exposure would be a deflection, but not abandonment, of their migratory path. More severe impacts on marine mammals, such as mortality or serious injury from vessel strikes, UXO detonation, and entanglement, are not anticipated due to the EPMs and additional measures that would be required as part of the environmental permitting processes. The incremental impact of the Proposed Action when compared to the No Action Alternative would be **minor** to **moderate** adverse for mysticetes, with moderate adverse impacts for humpback whale due to permanent hearing injury to individuals and for NARW due to potential exposure of several individuals to temporary behavioral disturbance in potentially important seasonal foraging habitats. Impacts to odontocetes would range from **minor** to **moderate**, with moderate impacts to harbor porpoise from permanent hearing injury to individuals. Pinnipeds would experience **minor** to **moderate** impacts to individuals from behavioral exposure and hearing injury to individuals. Mortality and non-auditory injury would not occur as a result of UXO detonation, only a few marine mammals of select species are anticipated to incur PTS incidental to pile driving and UXO detonation, vessel strike risk is very low and not anticipated, and accidental spills are also not anticipated. Because of the population status of NARW, the Project includes EPMs specifically designed to avoid and minimize adverse effects on this species. Implementation of these EMPs would effectively avoid greater than moderate effects on this species. Given this, the overall impact of the Proposed Action alone on marine mammals would be **moderate** adverse.

When including the baseline status of marine mammals into the impact findings and considering all phases of the Project, the impacts of the Proposed Action on NARW would be long term and **major** (primarily due to ongoing vessel strike and entanglement), and long term and **moderate** for other mysticetes. Impacts of the Proposed Action on odontocetes and pinnipeds would be long term and **minor** to **moderate**. Some **minor beneficial** impacts to certain odontocetes and pinnipeds could be realized through artificial reef effects. Beneficial effects, however, may be offset given the increased risk of entanglement due to derelict fishing gear and marine debris captured by offshore wind structures.

Cumulative Impacts of Alternative B, the Proposed Action. Existing environmental trends and ongoing activities would continue, and mysticetes, odontocetes, and pinnipeds would continue to be affected by natural and human-caused IPFs. Planned activities would contribute to impacts on marine mammals. Although injury or mortality of individuals may occur, long-term population-level effects are not anticipated for marine mammals (with the exception of NARW). Underwater noise impacts, vessel activity (vessel collisions), entanglement, and seabed disturbance, primarily from non–offshore wind activities, would result in **moderate** impacts. Accidental releases and discharges, EMF, the presence of structures, cable emplacement and maintenance, port utilization, and lighting associated with offshore wind activities would be implemented with measures to minimize impacts on marine mammals. Incremental impacts contributed by the Proposed Action to the cumulative impact on marine mammals would range from undetectable to noticeable. BOEM anticipates that the cumulative impacts for mysticetes, odontocetes, and pinnipeds in the GAA from the Proposed Action would be **moderate** to **major.** Long-term impacts to NARW would be **major** (due principally to baseline conditions), **moderate** for other mysticetes, and **minor** to **moderate** for odontocetes and pinnipeds. Impacts from the Proposed Action are not anticipated to substantially contribute to **major** long-term cumulative impacts for NARW. Some **minor beneficial** impacts to certain odontocetes and pinnipeds could be realized through artificial reef effects.

### 3.15.2.4 Alternatives C, D, E, and F

Under Alternatives C, D, E, and F, baseline conditions for marine mammals (see Section 3.15.1) would continue to follow current regional trends within the GAA. The impacts of existing conditions on marine mammals are described and analyzed in Appendix E1. The impacts of each IPF from the construction and installation, O&M, and conceptual decommissioning of Alternatives C, D, E, and F would be incremental to and would compound the impacts of baseline conditions on each marine mammal population considered in this EIS (see Table 3.15-2). These effects are described below.

#### 3.15.2.4.1 Construction and Installation

#### Offshore Activities and Facilities

Noise: Construction of Alternatives C through F would result in similar underwater noise impacts on marine mammals to those described for the Proposed Action in Section 3.15.2.2.1, but those impacts would be reduced in extent and duration because fewer structures would be installed. Reducing the number of structures is also expected to reduce the required extent of HRG surveys relative to the Proposed Action. It is assumed that 3,547 linear miles and 82 days of HRG survey effort would be required for the RWEC and OSS-link, plus 50 survey miles per linear mile of IAC cable at 43 miles of survey effort per day. The alternatives therefore range from 7,386 to 7,616 survey miles over 170–175 days for Alternative C, 7,951 to 8,846 survey miles over 183–204 days for Alternative E, and 9,279 to

10,142 survey miles over 213–233 days for Alternative E. Thus, the extent of HRG surveys is reduced proportional to the total number of structures proposed for each configuration. As of February 2023, 16 UXOs have been identified in the RWEC corridor (see Figure 2.1-10). Revolution Wind has determined that all 16 devices can be safely avoided by shifting the cable route within the approved installation corridor without the need for detonation (Orsted 2023). However, it is possible that additional devices of unknown size and location could be discovered during preconstruction surveys or construction that cannot be avoided or safely relocated. Impacts to marine mammals from HRG surveys and UXO detonation are considered to be similar in magnitude and general scale across all alternatives.

Differences in extent and duration of potential noise exposure from impact pile driving activities between the Proposed Action and the different configurations proposed for Alternatives C through E are summarized in Tables 3.15-12 through 3.15-14. These tables display the number of structures installed and estimated days of pile-driving activity required to construct each alternative. Extent and duration of potential noise exposure are proportional to the number of WTGs proposed; fewer WTGs would result in a smaller extent and shorter duration of impacts. For example, the two configurations of Alternative C and Alternative E1 would involve noticeably fewer days of pile driving than the Proposed Action and most configurations of Alternative D. While fewer individual marine mammals could be exposed to underwater noise impacts under these alternatives, the likelihood of at least some individuals being exposed to permanent injury remains. Accordingly, the impacts of this IPF would be noticeably reduced under these alternatives, the overall impacts would be similar in magnitude and general scale to those resulting from the Proposed Action. Adverse noise effects on marine mammals from each alternative for the duration of construction activities would likewise vary between species ranging from **minor** to **moderate** adverse. The potential use of larger capacity WTGs under Alternative F could result in more extensive operational noise impacts than the Proposed Action, but insufficient information is available to characterize differences in effect.

### 3.15.2.4.2 Operations and Maintenance and Decommissioning

#### Offshore Activities and Facilities

Presence of structures: The presence of WTG and OSS monopile foundations associated with Alternatives C through F would result in similar impacts to marine mammals as those described for the Proposed Action in Section 3.15.2.2.2, but those impacts would be reduced in extent and would vary depending on the alternative selected. Refer to Tables 3.6-17 through 3.6-19 in Section 3.6.2.4.2 for a summary of the number of structures under each proposed configuration of Alternatives C through F. As stated, Alternative F would employ one of the proposed configurations of Alternatives C through E using higher capacity WTGs. Aside from increased WTG capacity, all other features and impacts of Alternative F would be the same as those described for the selected configuration.

Over the life of the Project, the WTG and OSS foundations and associated scour protection would alter the offshore environment inhabited by marine mammals. Their presence could affect marine mammal behavior and indirectly affect the distribution and abundance of prey and forage species; however, the significance of these effects to a specific marine mammal species, such as NARW, is uncertain and would depend on the nature, extent, and significance of effects to forage species. For example, hydrodynamic effects from the presence of structures could alter the distribution of zooplankton and forage fish resources for baleen whales, leading those species to alter foraging patterns in response. These effects would likely influence the distribution of marine mammal forage species at a broad scale, but as discussed in Section 3.15.2.2.2, shifts in forage abundance and distribution would be expressed at smaller scales within this broader range. There is no basis to conclude that hydrodynamic effects would negatively affect the abundance and availability of prey species for marine mammals. The presence of structures and localized changes in forage species distribution could theoretically lead to displacement some marine mammal species and the potential for increased interaction with fisheries. Should such effects occur, they could lead to greater than negligible impacts on certain marine mammal species. However, insufficient information is available to determine if displacement effects are likely to occur and whether those effects would be biologically significant.

Impacts from the presence of structures are expected to vary in relation to the total number of foundations proposed (i.e., fewer structures would result in less extensive impacts). For example, both configurations of Alternative C and Alternative E1 propose noticeably fewer WTG and OSS foundations compared to the Proposed Action and most configurations of Alternative D. Therefore, these alternatives would be expected to produce noticeably reduced impacts from this IPF by comparison. In general, presence of structures effects on marine mammals under Alternatives C through F would likely be less extensive compared to those resulting from the Proposed Action. Reef effects would be reduced commensurate with the number of foundations constructed under each alternative configuration. At present, insufficient information is available to determine if differences in Project configuration between alternatives, specifically where foundations are located relative to sensitive benthic habitats, would contribute to a measurable difference in reef effects on marine mammals beyond those resulting from a simple reduction in the number of structures. As stated in Section 3.15.2.2.3, hydrodynamic effects are likely to lead to localized changes in the distribution of phytoplankton and forage fish prey for some marine mammal species, but these changes are unlikely to be biologically significant. Therefore, while Alternatives C through F would likely alter and reduce the extent of measurable hydrodynamic effects, those effects are likely to remain biologically insignificant. Following decommissioning and removal of the structures from the water column, the habitat would be expected to recover to conditions comparable to the environmental baseline for the surrounding habitats.

While certain alternative configurations would result in a noticeable reduction in the number of structures in the marine environment, it is not clear that this would result in a biologically significant difference in the effects of this IPF relative to the Proposed Action. It is not currently known if the presence of structures would result in displacement effects; therefore, it is not possible to determine if reducing the number of structures and altering their configuration would reduce displacement effects. Therefore, while Alternatives C through F would reduce the extent of reef and hydrodynamic effects, the overall impacts to marine mammals would be similar in magnitude and general scale to those resulting from the Proposed Action. On this basis, impacts from the presence of structures on marine mammals for Alternatives C through F are expected to range from **negligible** adverse to **minor** beneficial for the life of the Project. Impacts to specific species, such as NARW, are uncertain and would depend on several factors, including species-specific displacement effects, the nature and extent of effects to forage resources, and the status and sensitivity of the affected population to effects to individuals.

#### 3.15.2.4.3 Cumulative Impacts

##### Offshore Activities and Facilities

The cumulative impacts analysis for Alternatives C, D, E, and F is provided in Table 3.15-4.

#### 3.15.2.4.4 Conclusions

<u>Impacts of Alternatives C, D, E, and F.</u> As discussed in above sections, the anticipated impacts from these alternatives would reduce the number of WTGs and their associated IACs by approximately 10% to 43%, which would in turn result in an incremental reduction in effects on marine mammals from certain construction and installation, O&M, and conceptual decommissioning impacts. However, BOEM anticipates that any incremental reduction in impacts would not change the resulting effects on marine mammals to the extent necessary to alter the impact-level conclusions for any impact mechanism. The incremental impacts of Alternatives C, D, E, and F, when each is compared to the No Action Alternative, would be similar as the Proposed Action (i.e., **moderate** for NARWs, **minor** to **moderate** for other mysticetes, **minor** to **moderate** for odontocetes, and **minor** to **moderate** for pinnipeds) because, with the implementation of EPMs, mortality and non-auditory injury would not occur as a result of UXO detonation, only a few marine mammals of select species are anticipated to incur PTS incidental to pile driving and UXO detonation, vessel strike risk is very low and not anticipated, and accidental spills are also not anticipated.

The impacts resulting from Alternatives C, D, E, and F individually, when including the baseline status of marine mammals into the impact findings and considering all phases of the Project, would be similar to those of the Proposed Action and would be **minor** to **moderate** for mysticetes except for the NARW, which would be **major**. BOEM anticipates that the impacts resulting from the Proposed Action would be **minor to moderate** for odontocetes and pinnipeds and could include **minor beneficial** impacts. Adverse impacts are expected to result mainly from underwater noise (e.g., UXO detonations and impact pile driving) and increased vessel traffic potentially leading to vessel strikes. Beneficial impacts for odontocetes and pinnipeds are expected to result from the presence of structures.

Cumulative Impacts of Alternatives C, D, E, and F. The incremental impacts contributed by Alternatives C, D, E, and F to the cumulative impacts on marine mammals would be similar to those of the Proposed Action and would range from undetectable to noticeable. BOEM anticipates that the cumulative impacts of Alternatives C, D, E, and F when each is combined with ongoing and planned activities, including offshore wind, would be the same level as under the Proposed Action: **major** for NARW and **minor** to **moderate** for all other marine mammals. Some **minor beneficial** impacts to certain odontocetes and pinnipeds could be realized through artificial reef effects.

### 3.15.2.5 Alternative G: Impacts of the Preferred Alternative on Marine Mammals

Under Alternative G, baseline conditions for marine mammals (see Section 3.15.1) would continue to follow current regional trends within the GAA. The impacts of existing conditions on marine mammals are described and analyzed in Appendix E1. The impacts of each IPF from the construction and installation, O&M, and conceptual decommissioning of Alternative G would be incremental to and would compound the impacts of baseline conditions on each marine mammal population considered in this EIS (see Table 3.15-2). These effects are described below.

#### 3.15.2.5.1 Construction and Installation

#### Offshore Activities and Facilities

Noise: Construction of Alternative G would result in similar underwater noise impacts on marine mammals to those described for the Proposed Action in Section 3.15.2.3.1, but those impacts would be reduced in extent and duration because fewer structures would be installed. Reducing the number of structures could also reduce the required extent of HRG surveys relative to the Proposed Action, but BOEM has insufficient information to determine if this is the case. As of February 2023, 16 UXOs have been identified in the RWEC corridor. Revolution Wind has determined that all 16 devices can be safely avoided by shifting the cable route within the approved installation corridor without the need for detonation (Orsted 2023). However, it is possible that additional devices of unknown size and location could be discovered during preconstruction surveys or construction that cannot be avoided or safely relocated. Therefore, impacts to marine mammals from HRG surveys and UXO detonation are considered to be the same as for the Proposed Action.

Differences in the extent and duration of potential noise exposure from impact pile-driving activities between the Proposed Action and Alternative G are summarized in Table 3.15-15. This table displays the number of structures installed and estimated days of pile-driving activity required to construct the alternative. Extent and duration of potential noise exposure are proportional to the number of WTGs proposed; fewer WTGs would result in a smaller extent and shorter duration of impacts. While fewer individual marine mammals could be exposed to underwater noise impacts under these alternatives, the likelihood of at least some individuals being exposed to permanent injury remains. Accordingly, the impacts of this IPF would be noticeably reduced under this alternative, but the overall impacts would be similar in magnitude and general scale to those resulting from the Proposed Action. Adverse noise effects on marine mammals from Alternative G for the duration of construction activities would likewise vary between species, ranging from **minor** to **moderate** adverse.

**Table 3.15-15. Comparison of Maximum Underwater Noise Injury and Behavioral Effects Exposure Extent and Duration (number of sites/days) by Marine Mammal Hearing Group from Revolution Wind Farm WTG and OSS Foundation Installation, Proposed Action, and Proposed Configuration for Alternative G***

| Noise Exposure Type | Hearing Group | Threshold Distance for WTGs (feet)† | Threshold Distance for OSSs (feet)[†,§] | Proposed Action | Alternative G | Alternatives G1–G3 |
|---|---|---|---|---|---|---|
| Peak injury | LFC | < 33 | < 33 | 102 sites/ 35 days | 81 sites/ 28 days | 67 sites/ 24 days |
| | MFC | – | – | | | |
| | HFC | 525 | 361 | | | |
| | Phocids | – | | | | |
| Cumulative injury | LFC | 4,954–8,727 | 3,084–5,873 | | | |
| | MFC | 0–66 | – | | | |
| | HFC | 4,396 | 2,723 | | | |
| | Phocids | 787–1,444 | 33–1,214 | | | |
| TTS and behavioral effects | LFC | 11,909–12,336 | 11,516–11,877 | | | |
| | MFC | 0–12,041 | 0–11,909 | | | |
| | HFC | 11,877 | 11,483 | | | |
| | Phocids | 11,909–12,467 | 11,549–12,303 | | | |

* Installation scenario for a 12-m monopile is 10,740 strikes/pile at an installation rate of three piles/day. Installation scenario for 15-m monopile is 11,563 strikes/pile at an installation rate of up to two piles/day. All piles installed with a 4,000-kJ hammer with an attenuation system achieving 10 dB sound source reduction.

† Threshold distances are the distance in feet from the sound source where the identified type of exposure could occur. Values are the range threshold distances for monopile installation modeled by Kusel et al. (2023) across modeled sites during summer conditions.

§ Threshold distances for OSSs apply to two of the structures identified for each of the alternatives presented.

<u>Vessel traffic:</u> Alternative G would result in similar vessel traffic impacts on marine mammals to those described in Section 3.15.2.3.1. An estimate of vessel trips associated with Alternative G construction is not available; however, it is expected to be slightly less than the Proposed Action with effects commensurate with the reduction in vessel activities associated with 21 or 35 (depending on the configuration) fewer foundations.

Vessel collisions are a key source of mortality and serious injury for many marine mammal species (Hayes et al. 2021, 2022; Laist et al. 2001; Rockwood et al. 2017; Schoeman et al. 2020), indicating the importance of protective measures to minimize risks to vulnerable species. If a vessel strike does occur, the impact on marine mammals would range from **negligible** to **moderate** adverse, considering the application of project-specific EPMs. The applicant has committed to a range of EPMs to avoid vessel collisions with marine mammals (see Appendix F, Table F-1). These include adherence to NOAA guidance for collision avoidance and a combination of additional measures, including approved speed restrictions for all vessels within marine mammal SMAs and DMAs, and adherence to additional mitigation measures, as identified in Appendix F, Table F-1. All vessel crews would receive training to ensure that these EPMs are fully implemented for vessels in transit. Once on station, the construction vessels either remain stationary when installing the monopiles and WTG/OSS equipment or move slowly when traveling between foundation locations. Cable laying and HRG survey vessels also move slowly, with typical operational speeds of less than 1 knot and approximately 4 knots, respectively, and present minimal risk of collision-related injury.

The densities of the most common species of marine mammals likely to occur in the RWF Lease Area and RWEC route are generally low based on monthly mean density estimates developed by Roberts et al. (2016, 2017, 2018, 2020, 2021). Density and occurrence in and near the Lease Area vary by season and species; however, vessel strike avoidance measures would be implemented to minimize risk across the range of seasonal densities. Operational conditions combined with planned EPMs would minimize collision risk during construction and installation. Additional mitigation measures agreed upon through agency consultation would further reduce this risk (see Appendix F for all vessel strike avoidance measures). During periods of low visibility, trained crew would use increased vigilance to avoid marine mammals. Because vessel strikes are not an anticipated outcome given the relatively low number of vessel trips and EPMs to avoid encountering marine mammals, BOEM concludes vessel strikes are unlikely to occur. Therefore, there is no anticipated effect on marine mammals, and collision effects would be **negligible** adverse during Project construction.

The presence of construction vessels and associated noise and disturbance could cause short-term displacement of marine mammals from preferred habitats similar to the Proposed Action. Temporary marine mammal displacement from offshore wind energy construction sites have been observed, apparently due to vessel-related disturbance (Long 2017). Habitat use within the affected areas returned to normal after construction was completed, indicating that construction-related displacement effects would be short term in duration. On this basis, vessel displacement effects on marine mammals could range in significance from **minor** to **moderate** adverse depending on the species affected and the biological significance of displacement, recognizing that some portion of these effects is also likely the result of construction noise, as described above.

#### 3.15.2.5.2 Operations and Maintenance and Decommissioning

##### Offshore Activities and Facilities

Presence of structures: The presence of WTG and OSS monopile foundations associated with Alternative G would result in similar impacts to marine mammals as those described for the Proposed Action in Section 3.15.2.2.2, but those impacts would be reduced in extent due to the reduced number of structures.

Impacts from the presence of structures are expected to vary in relation to the total number of foundations proposed (i.e., fewer structures would result in less extensive impacts). Therefore, Alternative G would be expected to produce noticeably reduced impacts from this IPF by comparison. In general, presence of structures effects on marine mammals under this alternative is likely be less extensive compared to those resulting from the Proposed Action. Reef effects would be reduced commensurate with the number of foundations constructed. As stated in Section 3.15.2.3.2, hydrodynamic effects are likely to lead to localized changes in the distribution of phytoplankton and forage fish prey for some marine mammal species, but these changes are unlikely to be biologically significant. Therefore, while Alternative G would likely alter and reduce the extent of measurable hydrodynamic effects, those effects are likely to remain biologically insignificant. Following decommissioning and removal of the structures from the water column, the habitat would be expected to recover to conditions comparable to the environmental baseline for the surrounding habitats.

It is not currently known if the presence of structures would result in displacement effects; therefore, it is not possible to determine if reducing the number of structures and altering their configuration would reduce displacement effects. Therefore, while Alternative G would reduce the extent of reef and hydrodynamic effects, the overall impacts to marine mammals would be similar in magnitude and general scale to those resulting from the Proposed Action. On this basis, impacts from the presence of structures on marine mammals for Alternative G are expected to range from **negligible** adverse to **minor** beneficial for the life of the Project. Impacts to specific species, such as NARW, are uncertain and would depend on several factors, including species-specific displacement effects, the nature and extent of effects to forage resources, and the status of the affected population and sensitivity to effects to individuals.

#### 3.15.2.5.3 Cumulative Impacts

This section discloses potential impacts to marine mammals associated with future offshore wind development, including Alternative G. The cumulative impact analysis for Alternative G includes the proposed configurations of Alternative G, other planned non-offshore wind activities, as well as activities associated with constructed or approved offshore wind projects. Cumulative impacts to marine mammals under Alternative G presented herein would be incremental to and would compound the impacts of baseline conditions on each marine mammal population considered in this EIS (see Table 3.15-2).

##### Offshore Activities and Facilities

Anchoring and new cable emplacement/maintenance: BOEM estimates a cumulative total of 104,781 acres of cabling seafloor disturbance and 10,525 acres of anchoring disturbance for Alternative G, plus all other future offshore wind projects in the GAA. Cumulative impacts would be localized, temporary, **negligible** adverse to marine mammals through anchoring and cabling-related seafloor disturbance and associated increased suspended sedimentation within the GAA. No population-level effects on marine mammals are expected from reduced water quality. However, there could be temporary displacement of marine mammals from preferred habitats, especially during construction activities, due to increased vessel activity. Vessel anchoring and cable emplacement during construction and installation, O&M, and decommissioning are not anticipated to involve equipment, lines, or rigging that could pose a potential entanglement risk to marine mammals. Therefore, Alternative G combined with past, present, and reasonably foreseeable activities would result in **negligible** to **minor** adverse cumulative effects on marine mammals.

Climate change: Cumulative impacts to marine mammals from climate change under Alternative G are expected to be of similar magnitude to those described for the Proposed Action. The nature and potential significance of climate change cumulative impacts to marine mammals from Alternative G are unknown but are likely to range from **minor** to **moderate** adverse. Impacts to specific marine mammal species, such as NARW, would be influenced by the same factors described for the Proposed Action.

Noise: Alternative G would generate underwater noise effects during Project construction, throughout the operational life of the Project, and during Project decommissioning. Those impacts would be similar in magnitude and distribution but reduced in extent relative to the Proposed Action. These effects would combine with similar effects resulting from the construction, O&M, and decommissioning of other planned offshore wind projects on the Mid-Atlantic OCS.

All future actions would be subject to the same independent NEPA analysis and regulatory approvals as Alternative G. BOEM would require all projects to incorporate the same types of EPMs included in Alternative G to avoid and minimize harmful noise effects. While these measures would avoid and minimize impacts to marine mammals to the greatest extent practicable, some unavoidable impacts on individuals are likely to occur. The impacts of each project would result in **minor** to **moderate** adverse effects on marine mammals. Effects to specific marine mammal species would depend on the number of individuals exposed to injury and behavioral level effects, the significance of those effects to survival and reproductive fitness, and the status and sensitivity of the affected population to impacts to individuals. BOEM anticipates that future MMPA approvals would consider the known status of marine mammal stocks and populations, indirectly incorporating the potential combined effects of future projects. Therefore, BOEM concludes that the cumulative effects of construction noise on marine mammals would be **moderate** adverse because of the potential for PTS, TTS, and behavioral impacts during construction activities. NARW could be an exception to this determination because of its perilous population status. Hearing-related injury to even one individual that results in reduced reproductive fitness could contribute to ongoing downward trends in population viability. However, the application of EPMs is expected to minimize the risk of hearing-related injury.

Operational noise impacts would be similar in magnitude and distribution but reduced in extent relative to the Proposed Action. These structures would contribute to and potentially increase ambient noise within each WEA, albeit at levels generally not associated with adverse effects on marine mammals. While the potential for broader effects is unclear, BOEM concludes that the cumulative effects of low-level operational noise could raise to the level of **minor** adverse for certain marine mammal species.

Cumulative impacts to marine mammals from construction of Alternative G are expected to be of similar magnitude to those described for the Proposed Action. Alternative G is likely to result in short-term displacement effects on marine mammals from the areas affected by disturbance from vessel activity, foundation installation, HRG surveys, and related activities. Several projects are expected to be constructed concurrently, potentially resulting in individual marine mammals being exposed to multiple episodes of habitat displacement. BOEM anticipates that the construction schedules for future wind projects would employ the same types of timing restrictions to protect NARW as those included in the Proposed Action, with modifications as needed to adapt to ongoing shifts in the seasonal distribution of this species (e.g., Davis et al. 2017, 2020). However, timing restrictions for NARW would not be protective for all marine mammal species. It is anticipated that future wind projects would also employ a similar range of EPMs to avoid and minimize impacts to marine mammals, but some level of short-term displacement is likely to occur, and some individual animals are likely to be exposed to multiple episodes of displacement. The significance of these potential impacts is unclear, but when all protective measures are considered, cumulative effects are likely to range from **negligible** to **moderate** adverse, varying by species. Impacts to specific species, such as NARW, are uncertain and would depend on several factors, including the nature of cumulative climate change impacts to the availability and distribution of suitable habitat and forage resources, the ability of that species to adapt to these changes, and the status and resilience of the affected population.

<u>Presence of structures:</u> BOEM anticipates that future wind projects within the RI/MA WEA would be constructed using 1 × 1–nm grid spacing, as does the Proposed Action. Foundations spaced at 1 × 1 nm are unlikely to pose a barrier to movement for even the largest marine mammal species. However, the broad-scale development of offshore energy structures would introduce an extended network of biologically productive artificial reefs, most generating low levels of non-impulsive sound that are detectable to marine mammals within a few hundred feet. While the individual effects of each turbine would be **minor** adverse, the broader implications of these habitat changes for marine mammals are unclear. Displacement effects that result in increased interactions between vulnerable populations of marine mammals and commercial shipping and/or fishing activity could have noticeable long-term cumulative effects. Given these uncertainties, the potential for displacement effects is unknown, but there is currently no basis to conclude that these impacts would result in greater than **minor** adverse long-term effects on any species.

The abundance of fish and invertebrate prey resources created by the artificial reef effect are likely to attract predatory marine mammals, particularly seals (e.g., Russel et al. 2014) and potentially dolphins and porpoises. Increased fish biomass around the structures could attract commercial and recreational fishing activity, leading to increased interactions between humans and marine mammals. BOEM anticipates that future offshore wind projects would perform regular inspections to identify and remove derelict fishing gear and other marine debris from offshore structures, reducing associated risks to marine mammals.

The new wind energy structures would also cause hydrodynamic effects. The GAA is characterized by strong seasonal stratification, conditions that tend to limit the hydrodynamic influence of individual foundation structures (van Berkel et al. 2020). As discussed in the previous section, the Proposed Action is not anticipated to result in additive hydrodynamic effects. However, broader scale development of contiguous projects could have more extensive effects. For example, Afsharian et al. (2020) modeled the potential effects from installation of over 400 offshore wind turbines in Lake Erie and determined that their cumulative effect on wind energy could disrupt circulation patterns and affect seasonal stratification and water temperatures over broad scales. However, these findings may not be applicable to the open ocean, where circulation patterns are strongly influenced by tides and ocean currents.

At present, currently available information suggests that hydrodynamic effects of foundation structures are likely to be localized and not additive when spaced at 1 × 1 nm in environments with strong seasonal stratification (van Berkel et al. 2020). Recent modeling of hydrodynamic effects suggests that surface currents could be affected by the presence of multiple wind farms, potentially impacting the distribution of larvae (Johnson et al. 2021). There is insufficient information to determine if this conclusion is valid for broader scale development at the levels planned within the GAA. Therefore, at this time, there is no basis to conclude that the cumulative hydrodynamic impacts of the Proposed Action in combination with planned future actions would have a measurable effect on marine mammals and their prey and forage species.

In summary, the cumulative effects of long-term habitat alteration and hydrodynamic impacts on marine mammals are unclear, could be beneficial or adverse, could range from **negligible** to **moderate** adverse, and are likely to vary depending on several factors. These factors include the nature and extent of effects on habitat suitability and forage availability, the significance of these effects to the survival and reproductive fitness, and the status and sensitivity of affected populations to effects on individuals. Although the type and magnitude of effect from displacement and shifts in prey resources due to the presence of structures are largely unknown, the possibility of changes in distribution relative to commercial fishing activity and increased interaction with fishing gear poses the potential for increased risk of entanglement. Should such changes occur, increased risk of entanglement would constitute a **minor** to **moderate** adverse effect on marine mammals, because this stressor is a documented source of injury and mortality. Effects to each marine mammal species would depend on the number of individual animals exposed to entanglement effects, the nature of the impact (i.e., injury or mortality), and the status and sensitivity of the affected population to impacts to individuals. In the case of NARW, given that entanglement has been identified as a limiting factor in the species' recovery, the potential for increased exposure to entanglement could pose a significant risk; however, specific EPMs have been developed to minimize risk for NARW. The risk of entanglement is therefore not considered to result in a greater than moderate adverse effect for NARW. It is important to stress that the likelihood of this level of effect is unclear because it is not known if the presence of structures would displace NARW and whether displacement would lead to increased fishing gear exposure. These potential long-term impacts would persist until decommissioning is complete and structures are removed. EPMs would help to offset the potential impact of entanglement within derelict fishing gear or marine debris.

<u>Vessel traffic:</u> BOEM estimates that, cumulatively, up to 262 construction vessels could be active within the GAA between 2022 and 2030. As discussed above for Project construction, the majority of vessel operations would be expected to occur at speeds of less than 10 knots. In addition, BOEM anticipates that future projects would adhere to mandatory and voluntary vessel speed restrictions in posted DMAs and SMAs and would implement EPMs similar to those described for the Proposed Action (see Appendix F, Table F-1) to avoid marine mammal collisions BOEM has concluded that these measures would effectively avoid all but minor adverse impacts on sensitive species such as NARW and minimize risk of vessel collisions to other marine mammal species. Therefore, the cumulative effects of increased vessel traffic on marine mammals would range from **negligible** to **moderate** adverse.

#### 3.15.2.5.4 Conclusions

<u>Impacts of Alternative G, the Preferred Alternative</u>. As discussed above, the anticipated impacts from Alternative G reduce the number of WTGs and their associated IACs by approximately 35%, which

would result in an incremental reduction in effects on marine mammals from certain construction and installation, O&M, and conceptual decommissioning impacts. However, BOEM anticipates that any incremental reduction in impacts would not change the resulting effects on marine mammals to the extent necessary to alter the impact-level conclusions for any impact mechanism. The incremental impact of Alternative G, when compared to the No Action Alternative, would be similar to the Proposed Action: **minor** to **moderate** adverse for mysticetes, with moderate adverse impacts to humpback whale due to permanent hearing injury to individuals and to NARW due to potential exposure of several individuals to temporary behavioral disturbance in potentially important seasonal foraging habitats, respectively. Impacts to odontocetes would range from **minor** to **moderate**, with moderate impacts to harbor porpoise from permanent hearing injury to individuals. Pinnipeds would experience **minor** to **moderate** impacts to individuals from behavioral exposure and hearing injury to individuals. Because the implementation of EPMs would avoid mortality and non-auditory injury would not occur as a result of UXO detonation, only a few marine mammals of select species are anticipated to incur PTS incidental to pile driving and UXO detonation, vessel strike risk is very low and not anticipated, and accidental spills are also not anticipated.

The impacts resulting from Alternative G, when including the baseline status of marine mammals into the impact findings and considering all phases of the Project, would be similar to those of the Proposed Action and would be **moderate** for mysticetes except for the NARW, which would be **major**. BOEM anticipates that the impacts resulting from Alternative G would be **minor to moderate** for odontocetes and pinnipeds and could include **minor beneficial** impacts. Adverse impacts are expected to result mainly from underwater noise (e.g., UXO detonations and impact pile driving) and increased vessel traffic potentially leading to vessel strikes. Beneficial impacts for odontocetes and pinnipeds are expected to result from the presence of structures.

<u>Cumulative Impacts of Alternative G, the Preferred Alternative</u>. The incremental impacts contributed by Alternative G to the cumulative impacts on marine mammals would be similar to the Proposed Action and would range from undetectable to noticeable. BOEM anticipates that the cumulative impacts of Alternative G when combined with ongoing and planned activities, including offshore wind, would be the same as the Proposed Action: **major** for NARW and **minor** to **moderate** for all other marine mammals. Some **minor beneficial** impacts to certain odontocetes and pinnipeds could be realized through artificial reef effects.

#### 3.15.2.6 Summary of Impact Determinations to Marine Mammals for Use by NMFS in Review of the MMPA Incidental Take Regulation Application Pursuant to NEPA

This section, which includes Table 3.15-16, has been added to the Final EIS to assist the NMFS Office of Protected Resources to satisfy incremental impact analysis requirements under NEPA in support of their evaluation of Revolution Wind's application under MMPA (16 USC 1371(a)(5)(A)) for an ITR and associated Letter of Authorization and the decision of whether to issue the authorization. The incremental impact determinations presented in Table 3.15-16 summarize the incremental effect of each of the alternatives in Section 3.15.2 in the absence of baseline conditions and cumulative impacts from other planned and permitted offshore wind activities in the GAA.

Under the No Action Alternative, BOEM would not approve the RWF COP. Given this, stressors from construction, O&M, and conceptual decommissioning of the Project would not occur. Baseline conditions of the existing environment would remain unchanged. Therefore, not approving the COP would have no additional incremental effect on marine mammals. The No Action Alternative (i.e., not issuing the requested incidental take authorization under the MMPA) would also have no additional incremental impact on marine mammals and their habitat.

The determinations presented in Table 3.15-16 represent the combined incremental impacts of all IPFs from the associated alternative on the identified marine mammal species or species group. Where appropriate, incremental impacts are presented as a range where the anticipated effects of the alternative would differ between the species within that species group.

**Table 3.15-16. Summary of Incremental Impact Determinations to Marine Mammals across IPFs for Use by NMFS in Review of the MMPA ITR Application Pursuant to NEPA**

| Species | No Action Alternative | Alternative B (Proposed Action) | Alternative C (Habitat Alternative) | Alternative D (Transit Alternative) | Alternative E (Viewshed Alternative) | Alternative F (Higher Capacity Turbine Alternative) | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|---|---|
| NARW | No effect | Moderate | Moderate | Moderate | Moderate | Moderate | Moderate |
| Other mysticetes | No effect | Minor to moderate | Minor to moderate | Minor to moderate | Minor to moderate | Minor to moderate | Minor to moderate |
| Odontocetes | No effect | Minor to moderate | Minor to moderate | Minor to moderate | Minor to moderate | Minor to moderate | Minor to moderate |
| Pinnipeds | No effect | Minor to moderate | Minor to moderate | Minor to moderate | Minor to moderate | Minor to moderate | Minor to moderate |

Note: The incremental impacts of the action alternatives vary between the species within each species group and are therefore presented as a range.

#### 3.15.2.7 Mitigation

Mitigation measures resulting from agency consultations for marine mammals are identified in Appendix F, Table F-2, and addressed in Table 3.15-17. Additional mitigation measures identified by BOEM and cooperating agencies are listed in Appendix F, Table F-3, and summarized in Table 3.15-18.

**Table 3.15-17. Mitigation and Monitoring Measures Resulting from Consultations for Marine Mammals (Appendix F, Table F-2)**

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| Incorporate letter of authorization (LOA) requirements | The measures required by the final MMPA LOA for Incidental Take Regulations (ITRs) would be incorporated into COP approval, and BOEM and/or BSEE would monitor compliance with these measures. | Compliance with LOA requirements would reduce risks for marine mammals under the Proposed Action from pile driving, UXO detonation, HRG surveys, and vessel operations, and provide reporting and enforcement mechanisms to ensure all monitoring and mitigation requirements are implemented. However, this measure would not alter impact determinations for marine mammals because compliance with LOA requirements is an identified EPM that is considered in the analysis of the Proposed Action. |
| DRAFT NMFS BiOp Reasonable and Prudent Measures (RPMs) and Terms and Conditions (T&Cs) | Draft NMFS Biological Opinion Proposed Reasonable and Prudent Measures were issued to BOEM for consideration on June 16, 2023.<br>Final NMFS Biological Opinion Proposed Reasonable and Prudent Measures to be issued to BOEM for consideration on July 21, 2023.<br>RPMs and Terms and Conditions to minimize the impact of incidental take of ESA-listed species were documented in the draft NMFS Biological Opinion dated June 16, 2023. These measures include adherence to mitigation measures specified in the final MMPA ITA to minimize impacts during pile driving and UXO detonation; compliance with requirements for vessel operations within the Delaware River and Delaware Bay included in the Incidental Take Statements provided with the Paulsboro Marine Terminal Biological Opinion (dated July 19, 2022); reporting requirements related to effects to, or interactions with, ESA-listed species; submittal of required plans (e.g., PSO Training Plan for Trawl Surveys, Passive Acoustic Monitoring Plan, Marine Mammal and Sea Turtle Monitoring Plan, Cofferdam Installation and Removal Monitoring Plan, Alternative Monitoring Plan/Night Time Pile Driving Monitoring Plan, Sound Field Verification Plan, North Atlantic Right Whale Vessel Strike Avoidance Plan) to NMFS GARFO with sufficient time for review, comment and approval; and conducting on-site observation and inspection to gather | These RPMs and Terms and Conditions would minimize the exposure of ESA-listed marine mammals to underwater noise impacts from impact and vibratory pile driving, UXO detonation, and HRG surveys. These RPMs and Terms and Conditions would also ensure that all incidental take that occurs is documented and reported to NMFS in a timely manner. Reporting requirements to document take would improve accountability for documenting take associated with the Proposed Action. In some cases, these PRMs and Terms and Conditions provide additional detail or clarification of measures that are included as part of the Proposed Action. Implementation of these RPMs and Terms and Conditions would provide incremental reductions in impacts on marine mammals but would not alter the overall impact determination of the Proposed Action. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | information on the effectiveness and implementation of measures to minimize and monitor incidental take. | |
| NMFS EFH Conservation Recommendations | NMFS EFH Conservation Recommendations were issued to BOEM for consideration on June 16, 2023 (NMFS 2023).<br>EFH Conservation Recommendations for activities under BOEM's jurisdiction were provided identifying proposed removal and relocation (micrositing) of selected WTG foundations and cable segments removal and relocation; construction timing restrictions to avoid potential adverse impacts to Atlantic cod; habitat alteration minimization; noise mitigation; and minimization of impacts during construction, O&M, and decommissioning. EFH Conservation Recommendations for activities under USACE's jurisdiction were provided for in-water work; offshore impact minimization; impact to scientific surveys minimization; and identification and facilitated access to mapping of relocated boulders, berms, scour, and cable protection. | Implementation of Conservation Recommendations, for timing restrictions on all construction activity in the Lease Area from November 1 to April 30, and noise mitigation during construction, such as soft starts, use of noise-dampening equipment, and noise mitigation protocols in consultation with resource agencies prior to construction activities, would avoid and minimize potential underwater noise, vessel traffic, and seabed disturbance impacts on marine mammals during the restricted period. Implementation of Conservation Recommendations to develop monitoring plans for operational noise and vibration effects would benefit marine mammals by ensuring robust experimental design, methods, and data collection/analysis to assess changes in baseline underwater noise conditions. Although implementation of the Conservation Recommendations would provide incremental reductions noise and vessel-related disturbance reductions in the overall impact rating are not anticipated for any of the Proposed Action's IPFs. |
| Marine debris awareness training | The Lessee would ensure that vessel operators, employees, and contractors engaged in offshore activities pursuant to the approved COP complete marine trash and debris awareness training annually. The training consists of two parts: (1) viewing a marine trash and debris training video or slide show (described below); and (2) receiving an explanation from management personnel that emphasizes their commitment to the requirements. The marine trash and debris training videos, training slide packs, and other marine debris related educational material may be obtained at https://www.bsee.gov/debris or by contacting BSEE. The training videos, slides, and related material may be downloaded directly from the website. Operators engaged in marine survey activities must continue to develop and use a marine trash and debris awareness training and certification | Marine debris and trash awareness training would minimize the risk of marine mammal ingestion of or entanglement in marine debris. While adoption of this measure would decrease risk to marine mammals under the Proposed Action, it would not alter the impact determination for accidental releases. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | process that reasonably assures that their employees and contractors are in fact trained. The training process must include the following elements:<br>• Viewing of either a video or slide show by the personnel specified above;<br>• An explanation from management personnel that emphasizes their commitment to the requirements;<br>• Attendance measures (initial and annual); and<br>• Record keeping and the availability of records for inspection by DOI.<br>By January 31 of each year, the Lessee would submit to DOI an annual report that describes its marine trash and debris awareness training process and certifies that the training process has been followed for the previous calendar year. The Lessee would send the reports via email to BOEM (at renewable_reporting@boem.gov) and to BSEE via TIMSWeb with a notification email (at marinedebris@bsee.gov). | |
| Marine debris elimination | Materials, equipment, tools, containers, and other items used in OCS activities which could be lost or discarded overboard are of such shape or properly secured to prevent loss overboard must be clearly marked with the vessel or facility identification. All markings must clearly identify the owner and must be durable enough to resist the effects of the environmental conditions to which they may be exposed. | This measure would complement existing EPMs and regulatory requirements by providing a mechanism for enforcing accountability with EPMs and mitigation requirements, ensuring that impacts from the accidental releases and discharges IPF would remain negligible adverse. |
| Passive acoustic monitoring (PAM) plan | BOEM, BSEE, and USACE would ensure that Revolution Wind prepares a PAM plan that describes all proposed equipment, deployment locations, detection review methodology and other procedures, and protocols related to the required use of PAM for monitoring. This plan must be submitted to NMFS, BOEM, and BSEE (at OSWsubmittals@bsee.gov) for review and concurrence preferably 180 days but no later than 120 days to the planned start of pile driving. Reporting to BSEE must follow JOINT NTL 2023-N01, Appendix B (BSEE and BOEM 2023). | Revolution Wind has committed to implementing passive acoustic monitoring, pile driving monitoring, PSO coverage, sound field verification, and shutdown zones as part of the Proposed Action. Compliance with these EPMs would be enforced by BOEM, BSEE, and NMFS as indicated in Table F-2. Implementation and enforcement of these EPMs would minimize the potential for Level A or Level B exposures to marine mammals during of impact pile driving, vibratory pile driving, HRG surveys, and UXO |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | | detonation, as disclosed in the analysis of the Proposed Action. This agency-proposed mitigation measure specifies plan review and reporting requirements necessary to ensure PAM plan effectiveness and enforcement. While adoption of these measures would increase accountability and ensure the effectiveness of EPMs, it would not alter the impact determination for any marine mammal hearing group or individual species as analyzed herein. |
| Passive acoustic monitoring, long-term | Use PAM buoys or autonomous PAM devices to record ambient noise, marine mammals, and cod vocalizations in the Lease Area before, during, and immediately after construction (at least 25 years of operation (or as may be extended) to monitor Project noise. The archival recorders must have a minimum capability of detecting and storing acoustic data on anthropogenic noise sources (such as vessel noise, pile driving, WTG operation, and whale detections), marine mammals, and cod vocalizations in the Lease Area. Monitoring would also occur during the decommissioning phase. The total number of PAM stations and array configuration will depend on the size of the zone to be monitored, the amount of noise expected in the area, and the characteristics of the signals being monitored to accomplish both monitoring during constructions, and also meet post-construction monitoring needs. Results must be provided within 90 days of construction completion and again within 90 days of the 1-year, 2-year, and 3-year anniversary of collection. The underwater acoustic monitoring must follow standardized measurement and processing methods and visualization metrics developed by the Atlantic Deepwater Ecosystem Observatory Network (ADEON) for the U.S. Mid- and South Atlantic OCS (see https://adeon.unh.edu/). At least two buoys must be independently deployed within or bordering the Lease Area or one or more buoys must be deployed in coordination with other acoustic monitoring efforts in the RI/MA and MA WEAs. | Long-term PAM would provide data useful for documenting marine mammal presence in the Lease Area and vicinity and evaluating changes in population density and habitat use over the life of the project. This measure would not modify impact determinations on marine mammals but would provide the information necessary to ensure that these effects do not exceed the levels analyzed herein, and to inform existing uncertainty about potential effects on marine mammal species. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
| --- | --- | --- |
| | As an alternative to conducting PAM in its project area, the lessee may opt to meet this monitoring requirement through an annual deposit to BOEM's Environmental Studies Program in support of its Partnership for an Offshore Wind Energy Regional Observation Network (POWERON) initiative. The lessee's contribution would cover activities within its lease area, such as the purchase of instruments, annual deployments and refurbishment, data processing, and long-term data archiving. Funding from BOEM, other partners, and potentially other lessees will support long-term PAM throughout the region which will enable broader-scale analyses on cumulative effects to marine species. Under this option, the lessee will be expected to cooperate with the POWERON team to facilitate deployment and retrieval of instruments within the project area. If necessary, the lessee may request temporary withholding of the public release of acoustic data that has been collected within its project area. | |
| Sound field verification (SFV) | NMFS, BOEM, BSEE, and USACE would ensure that if the clearance and/or shutdown zones are expanded, PSO coverage is sufficient to reliably monitor the expanded clearance and/or shutdown zones. Additional observers must be deployed on additional platforms for every 1,500 m that a clearance or shutdown zone is expanded beyond the distances modeled prior to verification.<br><br>To validate the estimated sound field, SFV measurements would be conducted during pile driving of the first three monopiles installed over the course of the Project, with noise attenuation activated. A SFV plan would be submitted to NMFS, BOEM, USACE, and BSEE for review and approval preferably 180 days but no later than 120 days prior to planned start of pile driving. This plan would describe how Revolution Wind would ensure that the first three monopile installation sites selected for sound field are representative of the rest of the monopile installation sites and, in the case that they are not, how additional sites would be selected for SFV. This plan would also include methodology for collecting, analyzing, and preparing SFV data for submission to NMFS. The plan would describe how the effectiveness of the sound attenuation methodology would be | Revolution Wind has committed to implementing passive acoustic monitoring, pile driving monitoring, PSO coverage, sound field verification, and shutdown zones as part of the Proposed Action. Compliance with these EPMs would be enforced by BOEM, BSEE, and NMFS as indicated in Table F-2. Implementation and enforcement of these EPMs would minimize the potential for Level A or Level B exposures to marine mammals during of impact pile driving, vibratory pile driving, HRG surveys, and UXO detonation, as disclosed in the analysis of the Proposed Action. This agency-proposed mitigation measure specifies plan review and reporting requirements necessary to ensure SFV plan effectiveness and enforcement. While adoption of these measures would increase accountability and ensure the effectiveness of EPMs, it would not alter the impact determination for any marine mammal hearing group or individual species as analyzed herein. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | evaluated based on the results. In the event that Revolution Wind obtains technical information that indicates a subsequent monopile is likely to produce larger sound fields, SFV would be conducted for those subsequent monopiles. | |
| Shutdown zone and pre-start clearance zone adjustment | BOEM and BSEE, with the approval of NMFS, may consider adjustments in the pre-start clearance and/or shutdown zones based on the initial sound field verification measurements. If initial measurements indicate distances to the isopleths are greater than predicted by modeling, Revolution Wind must implement additional sound attenuation measures prior to conducting additional pile driving. | This measure would not modify the impact determination for noise effects on marine mammals (minor to moderate adverse) but would help to ensure that these effects do not exceed the levels analyzed herein. |
| Pile driving monitoring plan | BOEM, BSEE, and USACE would ensure that Revolution Wind prepares and submits to BSEE (via TIMSWeb and notification email at protectedspecies@bsee.gov) and BOEM (at renewable_reporting@boem.gov) for review and concurrence preferably 180 days but no later than 120 days before start of pile driving. Reporting to BSEE would follow JOINT NTL 2023-N01, Appendix B. The Lessee must not conduct pile driving operations at any time when lighting or weather conditions (e.g., darkness, rain, fog, sea state) prevent visual monitoring of the full extent of the clearance and shutdown zones including not initiating pile driving earlier than 1 hour after civil sunrise or later than 1.5 hours prior to civil sunset.<br><br>Pile driving at night may only occur with prior approval of an Alternative Monitoring Plan (AMP). The Lessee must submit an AMP to BOEM and NMFS for review and approval at least 6 months prior to the planned start of pile-driving. This plan may include deploying additional observers, alternative monitoring technologies such as night vision, thermal, and infrared technologies, or use of PAM and must demonstrate the ability and effectiveness to maintain all clearance and shutdown zones during daytime as outlined below in Part 1 and nighttime as outlined in Part 2 to BOEM's and NMFS's satisfaction. | Revolution Wind has committed to implementing passive acoustic monitoring, pile driving monitoring, PSO coverage, sound field verification, and shutdown zones as part of the Proposed Action. Compliance with these EPMs would be enforced by BOEM, BSEE, and NMFS as indicated in Table F-2. Implementation and enforcement of these EPMs would minimize the potential for Level A or Level B exposures to marine mammals during of impact pile driving, vibratory pile driving, HRG surveys, and UXO detonation, as disclosed in the analysis of the Proposed Action. This agency-proposed mitigation measure specifies plan review and reporting requirements necessary to ensure pile driving monitoring plan effectiveness and enforcement. While adoption of these measures would increase accountability and ensure the effectiveness of EPMs, it would not alter the impact determination for any marine mammal hearing group or individual species as analyzed herein. |

<table>
<tr><th>Mitigation Measure</th><th>Description</th><th>Expected Effect on Impacts from Action Alternatives</th></tr>
<tr><td></td><td>The AMP must include two stand-alone components as described below:<br><br>Part 1 – Daytime when lighting or weather (e.g., fog, rain, sea state) conditions prevent visual monitoring of the full extent of the clearance and shutdown zones. Daytime being defined as one hour after civil sunrise to 1.5 hours before civil sunset.<br><br>Part 2 – Nighttime inclusive of weather conditions (e.g., fog, rain, sea state). Nighttime being defined as 1.5 hours before civil sunset to one hour after civil sunrise.<br><br>If a protected marine mammal or sea turtle is observed entering or found within the shutdown zones after impact pile-driving has commenced, the Lessee would follow shutdown procedures outlined in the Protected Species Mitigation Monitoring Plan (PSMMP; Appendix B). The Lessee would notify BOEM and NMFS of any shutdown occurrence during piling driving operations within 24 hours of the occurrence unless otherwise authorized by BOEM and NMFS.<br><br>The AMP should include, but is not limited to the following information:<br>• Identification of night vision devices (e.g., mounted thermal/IR camera systems, hand-held or wearable NVDs, IR spotlights), if proposed for use to detect protected marine mammal and sea turtle species.<br>• The AMP must demonstrate (through empirical evidence) the capability of the proposed monitoring methodology to detect marine mammals and sea turtles within the full extent of the established clearance and shutdown zones (i.e., species can be detected at the same distances and with similar confidence) with the same effectiveness as daytime visual monitoring (i.e., same detection probability). Only devices and methods demonstrated as being capable of detecting marine mammals and sea turtles to the maximum extent of the clearance and shutdown zones will be acceptable.</td><td></td></tr>
</table>

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | • Evidence and discussion of the efficacy (range and accuracy) of each device proposed for low visibility monitoring must include an assessment of the results of field studies (e.g., Thayer Mahan demonstration), as well as supporting documentation regarding the efficacy of all proposed alternative monitoring methods (e.g., best scientific data available).<br>• Procedures and timeframes for notifying NMFS and BOEM of Revolution Wind's intent to pursue nighttime pile-driving.<br>• Reporting procedures, contacts and timeframes.<br>BOEM may request additional information, when appropriate, to assess the efficacy of the AMP. For mammals see Appendix B MMPA rule. | |
| PSO coverage | BOEM, BSEE, and USACE would ensure that PSO coverage is sufficient to reliably detect marine mammals and sea turtles at the surface in clearance and shutdown zones to execute any pile driving delays or shutdown requirements. If, at any point prior to or during construction, the PSO coverage that is included as part of the proposed action is determined not to be sufficient to reliably detect ESA-listed whales and sea turtles within the clearance and shutdown zones, additional PSOs and/or platforms must be deployed. Determinations prior to construction would be based on review of the Pile Driving Monitoring Plan. Determinations during construction must be based on review of the weekly pile driving reports and other information, as appropriate. | Revolution Wind has committed to implementing passive acoustic monitoring, pile driving monitoring, PSO coverage, sound field verification, and shutdown zones as part of the Proposed Action. Compliance with these EPMs would be enforced by BOEM, BSEE, and NMFS as indicated in Table F-2. Implementation and enforcement of these EPMs would minimize the potential for Level A or Level B exposures to marine mammals during of impact pile driving, vibratory pile driving, HRG surveys, and UXO detonation, as disclosed in the analysis of the Proposed Action. This agency-proposed mitigation measure specifies enforcement necessary to ensure that PSO coverage is sufficient to avoid and minimize adverse impacts to marine mammals. While adoption of these measures would increase accountability and ensure the effectiveness of EPMs, it would not alter the impact determination for any marine mammal hearing group or individual species as analyzed herein. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| Shutdown zones and pre-start clearance zone adjustment | BOEM, BSEE, and NMFS may consider adjustments in the pre-start clearance and/or shutdown zones based on the initial sound field verification (SFV) measurements. Revolution Wind will provide the initial results of each SFV measurement to BOEM, BSEE, and NMFS in an interim report after each monopile installation. Interim reports must be submitted as soon as they are available but no later than 48 hours after each installation.<br>Revolution Wind will conduct a SFV to empirically determine the distances to the isopleths corresponding to Level A harassment and Level B harassment thresholds, including at the locations corresponding to the modeled distances to the Level A harassment and Level B harassment thresholds. If initial SFV measurements indicate distances to the isopleths are less than the distances predicted by modeling assuming 10-dB attenuation, Revolution Wind may request a modification of the clearance and shutdown zones for impact pile driving. For a modification request to be considered, Revolution Wind must have conducted SFV on at least three piles to verify that zone sizes are consistently smaller than predicted by modeling. If initial SFV measurements from any foundation indicate distances to the isopleths are greater than the distances predicted by modeling, Revolution Wind will implement additional sound attenuation measures prior to conducting additional pile driving. Additional measures may include improving the efficacy of the implemented noise attenuation technology and/or modifying the piling schedule to reduce the sound source. If modeled zones cannot be achieved by these corrective actions, Revolution Wind must install an additional noise mitigation system to achieve the modelled ranges. Each sequential modification will be evaluated empirically by SFV of three additional foundations with the new sound attenuation technology. Additionally, in the event that SFV measurements continue to indicate distances to isopleths corresponding to Level A harassment and Level B harassment thresholds are consistently greater than the distances predicted by modeling, BOEM, BSEE, or NMFS may expand the | This measure would not modify the impact determination for noise effects on marine mammals (minor to moderate adverse) but establishes adaptive management measures and an enforcement mechanism to ensure these effects do not exceed the levels analyzed herein. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | relevant clearance and shutdown zones and associated monitoring measures. | |
| Vessel strike avoidance plan measures | BOEM must require Revolution Wind to comply with measures and reporting outlined in the final vessel strike avoidance plan per the MMPA ITR LOA, and NMFS's vessel strike avoidance and reporting measures included in the final MMPA ITR and ESA biological opinion. | Revolution Wind has committed to implementing a vessel strike avoidance policy, vessel separation distances, and vessel speed restrictions as part of the Proposed Action and as described in Table F-4. These measures include maintaining specified separation distances for NARW and unidentified large marine mammals, other large whales, and dolphins, porpoises, seals, and sea turtles. Revolution Wind's vessel strike avoidance policy directs that if an animal is sighted in the vessel's path, the vessel will divert or reduce speed and shift gears to neutral (see Table F-4). Project design criteria to minimize vessel interactions with listed species would further clarify the distance at which vessels would divert their path and the distance at which vessels would reduce speed and shift to neutral. Adoption of these measures would further clarify requirements for vessel strike avoidance under the Proposed Action but would not alter the impact determinations for any marine mammal species as analyzed herein. |
| Vessel strike PSO requirements | Protected Species Observer Requirements (Construction)(Operations)(Decommissioning). The Lessee must ensure that vessel operators and crew members maintain a vigilant watch for marine mammals and sea turtles, and reduce vessel speed, alter the vessel's course, or stop the vessel as necessary to avoid striking marine mammals or sea turtles.<br>All vessels must have a visual observer on board who is responsible for monitoring the vessel strike avoidance zone for marine mammals and sea turtles. Visual observers may be PSO or crew members, but crew members responsible for these duties must be provided sufficient training by the Lessee to distinguish marine mammals from other phenomena and must be able to identify a marine mammal as a North Atlantic right whale, other whale | Revolution Wind has committed to implementing passive acoustic monitoring, pile driving monitoring, PSO coverage, sound field verification, and shutdown zones as part of the Proposed Action. Compliance with these EPMs would be enforced by BOEM, BSEE, and NMFS as indicated in Table F-2. Implementation and enforcement of these EPMs would minimize the potential for Level A or Level B exposures to marine mammals during of impact pile driving, vibratory pile driving, HRG surveys, and UXO detonation, as disclosed in the analysis of the Proposed Action.<br>This agency-proposed mitigation measure specifies PSO coverage, monitoring, and notification requirements |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | (defined in this context as sperm whales or baleen whales other than North Atlantic right whales), or other marine mammal. Crew members serving as visual observers must not have duties other than observing for marine mammals while the vessel is operating over 10 kts;<br>Vessel Communication of Threatened and Endangered Species Sightings (Planning) (Construction) (Operations) (Decommissioning). The Lessee must ensure that whenever multiple Project vessels are operating, any detections of ESA-listed species (marine mammals and sea turtles) are communicated in near real time to these personnel on the other Project vessels: Protected Species Observer (PSO), vessel captains, or both.<br>Year-round, all vessel operators must monitor, the project's Situational Awareness System, WhaleAlert, US Coast Guard VHF Channel 16, and the Right Whale Sighting Advisory System (RWSAS) for the presence of North Atlantic right whales once every 4-hour shift during project-related activities. The PSO and PAM operator monitoring teams for all activities must also monitor these systems no less than every 12 hours. If a vessel operator is alerted to a North Atlantic right whale detection within the project area, they must immediately convey this information to the PSO and PAM teams. For any UXO/MEC detonation, these systems must be monitored for 24 hours prior to blasting;<br>Any observations of any large whale by any of the Lessee's staff or contractor, including vessel crew, must be communicated immediately to PSOs and all vessel captains to increase situational awareness. | necessary to avoid and minimize vessel strike risk to marine mammals. While adoption of these measures would increase accountability and ensure the effectiveness of EPMs, it would not alter the impact determination for any marine mammal hearing group or individual species as analyzed herein. |
| Vessel speed requirements | Between November 1st and April 30th, all vessels, regardless of size, must operate at 10 kts or less when traveling between the lease area and ports in New Jersey, New York, Maryland, Delaware, and Virginia;<br>All vessels, regardless of size, must immediately reduce speed to 10 kts or less when any large whale, mother/calf pairs, or large | Revolution Wind has committed to implementing passive acoustic monitoring, pile driving monitoring, PSO coverage, sound field verification, and shutdown zones as part of the Proposed Action. Compliance with these EPMs would be enforced by BOEM, BSEE, and NMFS as indicated in Table F-2. Implementation and enforcement of these EPMs would minimize the potential for Level A or |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | assemblages of non-delphinid cetaceans are observed (within 500 m) of an underway vessel;<br>All vessels, regardless of size, must immediately reduce speed to 10 kts or less when a North Atlantic right whale is sighted, at any distance, by anyone on the vessel;<br>If a vessel is traveling at greater than 10 knots, in addition to the required dedicated visual observer, the Lessee must monitor the transit corridor in real-time with PAM prior to and during transits. If a North Atlantic right whale is detected via visual observation or PAM within or approaching the transit corridor, all crew transfer vessels must travel at 10 kts or less for 12 hours following the detection. Each subsequent detection shall trigger a 12-hour reset. A slowdown in the transit corridor expires when there has been no further visual or acoustic detection in the transit corridor in the past 12 hours;<br>All underway vessels (e.g., transiting, surveying) operating at any speed must have a dedicated visual observer on duty at all times to monitor for marine mammals within a 180° direction of the forward path of the vessel (90° port to 90° starboard) located at an appropriate vantage point for ensuring vessels are maintaining appropriate separation distances. Visual observers must be equipped with alternative monitoring technology for periods of low visibility (e.g., darkness, rain, fog, etc.). The dedicated visual observer must receive prior training on protected species detection and identification, vessel strike minimization procedures, how and when to communicate with the vessel captain, and reporting requirements in this subpart. Visual observers may be third-party observers (i.e., NMFS-approved PSOs) or crew members. Observer training related to these vessel strike avoidance measures must be conducted for all vessel operators and crew prior to the start of in-water construction activities. Confirmation of the observers' training and understanding of the ITA requirements must be documented on a training course log sheet and reported to NMFS; | Level B exposures to marine mammals during of impact pile driving, vibratory pile driving, HRG surveys, and UXO detonation, as disclosed in the analysis of the Proposed Action. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | All vessels must maintain a minimum separation distance of 500 m from North Atlantic right whales. If underway, all vessels must steer a course away from any sighted North Atlantic right whale at 10 kts or less such that the 500-m minimum separation distance requirement is not violated. If a North Atlantic right whale is sighted within 500 m of an underway vessel, that vessel must shift the engine to neutral. Engines must not be engaged until the whale has moved outside of the vessel's path and beyond 500 m. If a whale is observed but cannot be confirmed as a species other than a North Atlantic right whale, the vessel operator must assume that it is a North Atlantic right whale and take the vessel strike avoidance measures described in this paragraph (b)(2)(xi);<br>All vessels must maintain a minimum separation distance of 100 m from sperm whales and non-North Atlantic right whale baleen whales. If one of these species is sighted within 100 m of an underway vessel, that vessel must shift the engine to neutral. Engines must not be engaged until the whale has moved outside of the vessel's path and beyond 100 m;<br>All vessels must, to the maximum extent practicable, attempt to maintain a minimum separation distance of 50 m from all delphinoid cetaceans and pinnipeds, with an exception made for those that approach the vessel (e.g., bow-riding dolphins). If a delphinid cetacean or pinniped is sighted within 50 m of an underway vessel, that vessel must shift the engine to neutral, with an exception made for those that approach the vessel (e.g., bow-riding dolphins). Engines must not be engaged until the animal(s) has moved outside of the vessel's path and beyond 50 m;<br>When a marine mammal(s) is sighted while a vessel is underway, the vessel must take action as necessary to avoid violating the relevant separation distances (e.g., attempt to remain parallel to the animal's course, avoid excessive speed or abrupt changes in direction until the animal has left the area). If a marine mammal(s) is sighted within the relevant separation distance, the vessel must reduce speed and shift the engine to neutral, not engaging the engine(s) until the animal(s) is clear of the area. This does not | |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | apply to any vessel towing gear or any situation where respecting the relevant separation distance would be unsafe (i.e., any situation where the vessel is navigationally constrained);<br>All vessels underway must not divert or alter course to approach any marine mammal. Any vessel underway must avoid speed over 10 kts or abrupt changes in course direction until the animal is out of an on a path away from the separation distances; and<br>For in-water construction heavy machinery activities other than impact or vibratory pile driving, if a marine mammal is on a path towards or comes within 10 m of equipment, the Lessee must cease operations until the marine mammal has moved more than 10 m on a path away from the activity to avoid direct interaction with equipment. | |
| Vessel speed restriction | All vessels, regardless of size, would comply with a 10-knot speed restriction in any SMA, DMA, or Slow Zone.<br>On August 1, 2022, NMFS published a proposed rule for changes to NARW vessel speed regulations to further reduce the likelihood of mortalities and serious injuries from vessel collisions (87 Federal Register [FR] 46921. If the proposed rule becomes final, BOEM would require appropriate restrictions per area. | This measure would complement existing EPMs and ensure their effectiveness. Although it would not modify the impact determination for vessel-related displacement effects on marine mammals (minor to moderate adverse), it would help to ensure that these effects do not exceed the levels analyzed herein. |
| Sampling gear | All sampling gear must be hauled out at least once every 30 days, and all gear must would be removed from the water and stored on land between survey seasons to minimize risk of entanglement. | This measure would complement existing EPMs and ensure that entanglement risk and potential impacts on marine mammals remain negligible. |
| Lost survey gear | If any survey gear is lost, all reasonable efforts that do not compromise human safety must be undertaken to recover the gear. All lost gear must be reported to NMFS (nmfs.gar.incidental-take@noaa.gov) and BSEE (via TIMSWeb and notification email at marinedebris@bsee.govOSWIncidentReporting@bsee.gov) within 24 hours of the documented time of missing or lost gear. This report must include information on any markings on the gear and any efforts undertaken or planned to recover the gear. | This measure would complement existing EPMs and ensure that entanglement risk and potential impacts on marine mammals remain negligible. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| Training | At least one of the survey staff onboard the trawl surveys and ventless trap surveys must have completed NEFOP observer training (within the last 5 years) or other training in protected species identification and safe handling (inclusive of taking genetic samples from Atlantic sturgeon). Reference materials for identification, disentanglement, safe handling, and genetic sampling procedures must be available on board each survey vessel. BOEM and BSEE would ensure that Revolution Wind prepares a training plan that addresses how this requirement would be met and that the plan is submitted to NMFS in advance of any trawl or trap surveys. This requirement is in place for any trips where gear is set or hauled. | This measure would complement existing EPMs and ensure that entanglement risk and potential impacts on marine mammals remain negligible. |
| Monthly/ annual reporting requirements | BOEM and BSEE would ensure that Revolution Wind submits regular reports (in consultation with NMFS) necessary to document the amount or extent of take that occurs during all phases of the proposed action. Details of reporting must be coordinated between Revolution Wind, NMFS, BOEM and BSEE. All reports would be sent to: nmfs.gar.incidental- take@noaa.gov and via TIMSWeb and notification email at protectedspecies@bsee.gov. | This measure would not modify the impact determination for marine mammals, but it would provide the information necessary to ensure that effects do not exceed the levels analyzed herein. |
| Periodic underwater surveys, reporting of monofilament and other fishing gear around WTG foundations | BOEM will require Lessee to monitor potential loss of fishing gear in the vicinity of WTG foundations by surveying at least ten percent of the total installed foundations annually. Survey design and effort may be modified based upon previous survey results after review and concurrence by BOEM. The Lessee must conduct surveys by remotely operated vehicles, divers, or other means to determine the locations and amounts of marine debris. The Lessee must submit annual reports to BOEM and BSEE by no later than April of the year following the survey. Survey reports will meet all requirements specified in Appendix F, Table F-2. Required data and reports may be archived, analyzed, published, and disseminated by BOEM. | This measure would not modify the impact determination for marine mammals, but it would provide the information necessary to ensure that effects do not exceed the levels analyzed herein. |
| Data collection BA BMPs | BOEM and BSEE must ensure that all Project design criteria and BMPs incorporated in the Atlantic Data Collection consultation for | This measure would not modify impact determinations on marine mammals but would provide the information |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | Offshore Wind Activities (BOEM 2021c) shall be applied to activities associated with Project construction and O&M, as applicable. | necessary to ensure that these effects do not exceed the levels analyzed herein. |
| Reporting of all North Atlantic right whale (NARW) sightings | If a NARW is observed at any time by PSOs or personnel on any Project vessels, during any Project-related activity, or during vessel transit, Revolution Wind must report the sighting information to NMFS as soon as feasible and no later than within 24 hours after conclusion of the detection event (the time, location, number of animals, closest point of approach of animals, animal behavior, activities at time of detection, vessel speed, and any mitigation measures implemented) via the WhaleAlert app (http://www.whalealert.org/), NMFS Right Whale Sighting Advisory System hotline (phone), and PR.ITP.MonitoringReports@noaa.gov. | This measure would not modify the impact determination for any IPF but would contribute to improved understanding of marine mammal use of the RWF and vicinity. |
| Long-term PAM (proposed by BOEM) | Long-term monitoring of ambient noise, marine mammal, and cod vocalizations in the Lease Area before, during, and following construction. Continuous recording must occur at least 30 days prior to pile driving, during foundation pile driving, initial operation, and for at least 3 full calendar years of operation to monitor for potential impacts. At least three devices must be independently deployed within the lease area to maximize spatial coverage of the project area based on 10-kilometer spacing between deployment locations or as otherwise agreed between BOEM and the Lessee. The locations of the three buoys must be coordinated with the Regional Wildlife Science Collaborative prior to the plan being submitted to BOEM and BSEE. Devices may be moved to new locations during the recording period, if existing PAM devices will be present in the lease area providing continuous recording. The archival recorders must have a minimum capability of continuously detecting and storing acoustic data on vessel noise, pile-driving, WTG operation, baleen whale vocalizations, and cod vocalizations in the lease area. No later than 180 days prior to buoy deployment, the Lessee must submit to BOEM and BSEE (renewable_reporting@boem.gov and OSWsubmittals@bsee.gov) the PAM plan, which describes all proposed equipment, deployment locations, detection review methodology, and other | Long-term PAM would provide data useful for documenting marine mammal presence in the Lease Area and vicinity and evaluating changes in population density and habitat use over the life of the project. This measure would not modify impact determinations on marine mammals but would provide the information necessary to ensure that these effects do not exceed the levels analyzed herein, and to inform existing uncertainty about potential effects on marine mammal species. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | procedures and protocols related to the required use of PAM for monitoring.<br>The PAM plan must detail mooring best practices, data management, storage, measurement, and data processing best practices that are required by BOEM for long-term PAM monitoring. Refer to Regional Wildlife Science Collaborative for Offshore Wind Data Management & Storage Best Practices for Long-term and Archival Passive Acoustic Monitoring (PAM) Data. Other best practices consistent with COP approval should be detailed in the plan. The long-term PAM Plan must include the proposed equipment, sample rate, mooring design, deployment locations, methods for baleen whale and cod detections, and metrics for ambient noise analysis. The long-term PAM plan must be submitted to BOEM and BSEE (at renewable_reporting@boem.gov and OSWsubmittals@bsee.gov) for review and concurrence. BOEM and BSEE will review the long-term PAM Plan and provide comments, if any, on the plan within 45 calendar days, but no later than 90 days of its submittal. The plan must satisfy all outstanding comments to BOEM's and BSEE's satisfaction. The Lessee will receive written concurrence from DOI upon acceptance of the final long-term PAM plan. If DOI does not provide comments on the long-term PAM Plan within 90 calendar days of its submittal, the Lessee may conclusively presume DOI's concurrence with the long-term PAM Plan.<br>Long-term PAM monitoring results must be provided within 180 days of buoy collection and again within 180 days of the annual anniversaries of each the PAM device deployments. All raw data must be sent to NCEI for archiving no later than 6 months following the date of each recorder recovery.<br>As an alternative to conducting long-term PAM in its project area, the lessee may opt to meet this monitoring requirement through an annual deposit to BOEM's Environmental Studies Program in support of its Partnership for an Offshore Wind Energy Regional Observation Network (POWERON) initiative. The lessee's contribution would cover activities within the area of potential | |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | effect of the project, such as the purchase of instruments, annual deployments and refurbishment, data processing, and long-term data archiving. Funding from BOEM, other partners, and potentially other lessees will support long-term PAM throughout the region which will enable broader-scale analyses on cumulative effects to marine species. Under this option, the Lessee will be expected to cooperate with the POWERON team to facilitate deployment and retrieval of instruments within the project area. If necessary, the Lessee may request temporary withholding of the public release of acoustic data that has been collected within its project area. Record long-term measurements of ambient noise, marine mammal, and cod vocalizations in the Lease Area before, during, and following construction. | |

**Table 3.15-18. Additional Mitigation and Monitoring Measures Under Consideration for Marine Mammals (Appendix F, Table F-3)**

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| Federal survey mitigation | There are 14 NMFS scientific surveys that overlap with wind energy development in the northeast region and eight of these surveys overlap with the Project. As per NMFS and BOEM Survey Mitigation strategy actions 1.3.1, 1.3.2, 2.1.1, and 2.1.2 (Hare et al. 2022), within 120 calendar days of COP Approval, the Lessee must submit to BOEM a draft survey mitigation agreement between NMFS and the Lessee. The survey mitigation agreement will describe how the Lessee will mitigate the Project impacts on the eight NMFS surveys. If after consultation with NMFS NEFSC, BOEM deems the survey mitigation agreement acceptable, the mitigation will be considered required as a term and condition of the Project's COP approval.<br>As soon as reasonably practicable, but no later than 30 days after the issuance of the Project's COP Approval, the Lessee will initiate coordination with NMFS NEFSC to develop the survey mitigation agreement described above. Mitigation activities specified under the agreement will be designed to mitigate the Project impacts on the | This measure provides a mechanism to avoid and minimize adverse impacts of project O&M on scientific surveys used to monitor the status of marine mammal populations and their forage and prey organisms. The implementation of this measure would ensure that federal surveys continue to provide the data and information necessary to monitor marine mammal population status. Federal survey data will be used to ensure that impacts to marine mammals remain within the levels considered in this FEIS, and to address uncertainties identified in impact analysis. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | following NMFS NEFSC surveys: (a) Spring Bottom Trawl survey; (b) Autumn Multi-species Bottom Trawl survey; (c) Ecosystem Monitoring survey; (d) NARW aerial survey; (e) Aerial marine mammal and sea turtle survey; (f) Shipboard marine mammal and sea turtle survey; (g) Atlantic surfclam and ocean quahog survey; and (h) Atlantic sea scallop survey. At a minimum, the survey mitigation agreement will describe actions needed and the means to address impacts on the affected surveys due to the preclusion of sampling platforms and impacts on statistical designs. In terms of statistical design, the project will be viewed as a discrete stratum in surveys that use a random stratified design. Other anticipated Project impacts on NMFS surveys such as changes in habitat and increased operational costs due to loss of sampling efficiencies may also be addressed in the agreement.<br>The survey mitigation agreement will identify activities that will result in the generation of data equivalent to data generated by NMFS's affected surveys for the duration of the Project. The survey mitigation agreement will describe the implementation procedures by which the Lessee will work with NEFSC to generate, share, and manage the data required by NEFSC for each of the surveys impacted by the Project, as mutually agreed upon between the Lessee and NMFS/NEFSC. The survey mitigation agreement must also describe the Lessee's participation in the NMFS NEFSC Northeast Survey Mitigation Program to support activities that address regional-level impacts for the surveys listed above. | |

#### 3.15.2.7.1 Measures Incorporated into the Preferred Alternative

Mitigation measures required through completed consultations, authorizations, and permits listed in Table 3.15-16 and in Appendix F, Table F-2, are incorporated into Alternative G (Preferred Alternative). BOEM has identified additional measures in Table 3.15-17. These measures, if adopted, would further define how the effectiveness and enforcement of EPMs would be ensured and improve accountability for compliance with EPMs by requiring the submittal of plans for approval by the enforcing agency(ies) and by defining reporting requirements. Because these measures ensure the effectiveness of and compliance with EPMs that are already analyzed as part of the Proposed Action, implementation of these measures would not further reduce the impact level of the Proposed Action from what is described in Section 3.15.2.

# 3.16 Navigation and Vessel Traffic

## 3.16.1 Description of the Affected Environment for Navigation and Vessel Traffic

Geographic analysis area: The GAA for navigation and vessel traffic impacts includes the Lease Area, all other wind energy lease areas (for the cumulative effects analysis), and the bays surrounding each of the ports listed in Section 3.11 as being potentially used by the Project during construction or operations, as shown in Figure 3.16-1.

In Figure 3.16-1, "Wind Farm Ports (Listed in the COP)" are those potentially used for construction or operations activities, including WTG tower, nacelle, and blade storage; pre-commissioning and marshalling; foundation marshalling and advanced foundation component fabrication; and construction hub and/or O&M activities (see COP Table 3.3.10-1 [VHB 2023]). "Commercial Fishing Only" refers to those ports identified as commercial fishing or for-hire recreational fishing ports, as discussed in Section 3.11.

The OCS-A 0501 and OCS-A 0517 wind energy lease areas are included under Alternative A. The other wind energy lease areas considered in the cumulative analysis include the following RI/MA WEA and MA WEA Lease Areas: OCS-A 0487, OCS-A 0500, OCS-A 0520, OCS-A 0521, and OCS-A 0522. See Table E-3 in Appendix E for more information.

Affected environment: The navigational safety risk assessment (NSRA) (DNV GL Energy USA, Inc. 2020) analyzed all vessels with Automatic Identification System (AIS) data[45] using data for July 1, 2018, through June 30, 2019, supplemented with vessel monitoring system (VMS) data for calendar year 2016, density maps, the final USCG (2020) report *The Areas Offshore of Massachusetts and Rhode Island Port Access Route Study* (MARIPARS), and stakeholder input (DNV GL Energy USA, Inc. 2020). The assessment used a 5-mile radius around the Project to determine the vessel types transiting in the area during this time period and evaluation incidents; AIS data suggest that primarily only fishing and other/unidentified vessels currently transit within the Lease Area.

[45] AIS data cover those vessels that are required to carry a transponder—or that choose to carry one—according to AIS requirements at 33 CFR 164.01, 164.02, 164.46, and 164.53. Most smaller vessels are not covered in the data. AIS data underestimate the scale of commercial fishing vessel activities, as transponders are only required for vessels over 65 feet and can be turned off after 12 nm. See Section 3.9 for a discussion of VMS data used for commercial fishing vessels.

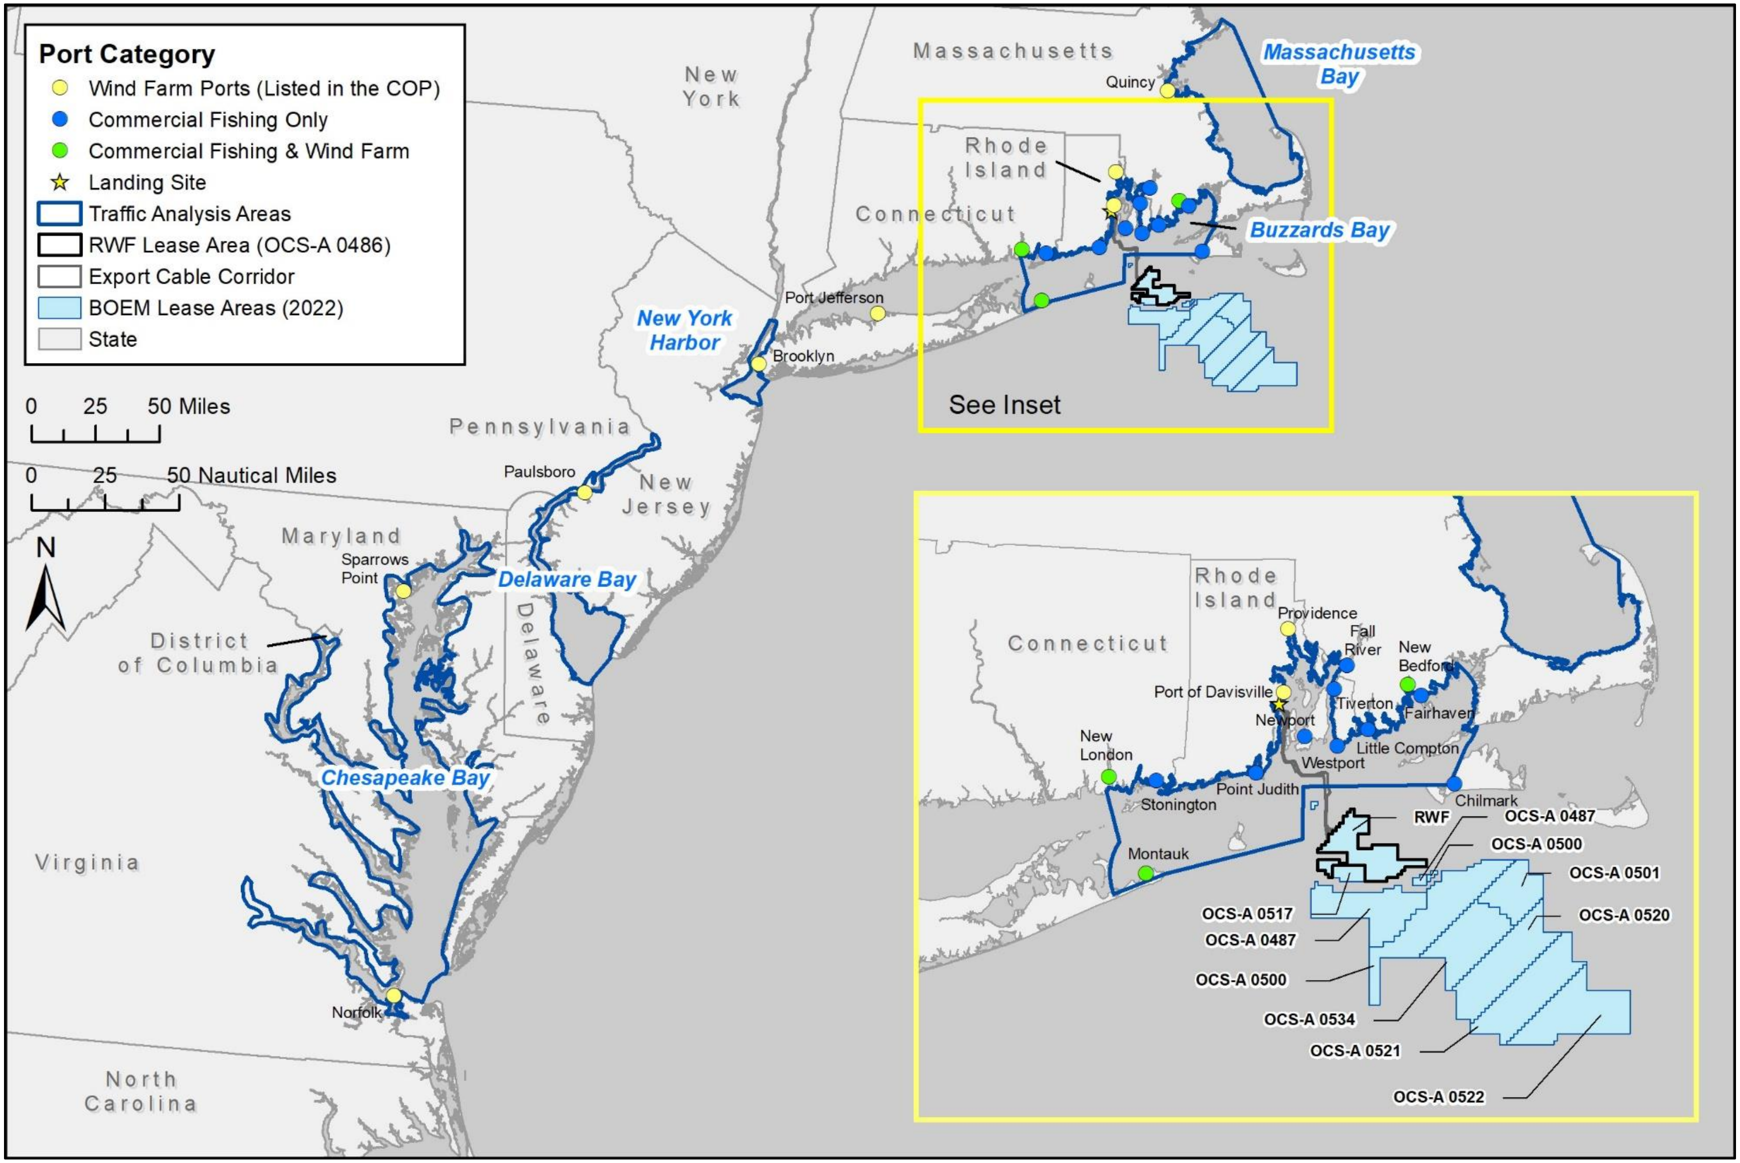

**Figure 3.16-1. Geographic analysis area for navigation and vessel traffic.**

MARIPARS analyzed AIS data within the leased areas of the RI/MA WEA and MA WEA (study area) shown in Figure 3.16-1[46] (USCG 2020:Figure 3). The MARIPARS study found 13,000 to 46,900 annual vessel transits through the study area. Activity during the summer months was quadruple that of January and February. The study concluded that vessel activity in the study area was largely commercial fishing. Fishing vessels primarily originated from several ports in Rhode Island, Massachusetts, or New York and transited the study area to reach fishing grounds and other areas southeast of the study area. Recreational vessels were more expected to transit within the structure arrays and less expected to use USCG designated routes. Passenger vessels largely did not transit the study area. Deep draft and towing vessels transited the study area, mostly on the west side, and tug and towing vessels had a low frequency of transit in the study area. MARIPARS did not evaluate other and unidentified vessels, although many appeared to be misclassified fishing vessels.

AIS data for 2019 (Office for Coastal Management [OCM] 2020) were further analyzed to measure the time and distance that vessels spent within the Lease Area. In 2019, vessels traveled 42,424 miles in the Lease Area. The majority of miles are attributed to fishing vessels, which accounted for 39% of all vessel miles traveled. Pleasure craft accounted for 6% of miles (Table 3.16-1). Table 3.16-2 summarizes activity in the basins in the GAA, as measured by miles traveled. Chesapeake Bay had the most activity, and pleasure craft/sailing vessels were the most common vessel there. New York Harbor was the second busiest, with passenger vessels contributing more than half of the activity. Tug tow vessels accounted for a substantial number of miles traveled in Chesapeake Bay, New York Harbor, and Delaware Bay (each with more than 500,000 miles traveled). Fishing vessels had the most activity in Buzzards Bay. Deep draft vessels accounted for very little of the activity; the largest contribution was in Chesapeake Bay, with 537,000 miles of 3,775,000 miles total.

**Table 3.16-1. Distance Vessels Traveled inside Lease Area (miles)**

| Vessel Type | Revolution Wind Lease Area | Other Contiguous Rhode Island/Massachusetts Wind Energy Area Lease Areas* |

Source: Developed using OCM (2020).

Figures 3.16-2 and 3.16-3 show close-up views of the Project with vessel traffic (based on AIS data). Tanker cargo vessels and tug and towing vessels generally travel in the internationally designated traffic separation schemes to the north and west of the Lease Area. These vessels can approach or exit the Narragansett Bay traffic separation scheme in a northwest–southeast orientation, leading some to transit through the Lease Area. East of and at the approximate latitude of Old Harbor, cargo vessels diverge from the north–south traffic lanes, and some transit through the Lease Area. Passenger vessels, typically ferries or cruise ships, generally avoid the Lease Area and would often follow a similar route. The Lease Area is located outside the designated lanes used by most commercial vessel traffic.

Fishing vessels operate all over the region, sometimes fishing and often transiting, with their vessel movements recorded through AIS, VMS, or not at all (see Section 3.9.1). Relative to the areas closer to the coast and traffic lanes, there is less vessel traffic near the Lease Area.

The NSRA modeled vessel incident data, showing no collisions or allisions in the Lease Area and estimating a total of 0.7543 collisions per year and no allisions in the NSRA's study area, which included the Lease Area (DNV GL Energy USA, Inc. 2020:Table E-6). The results of the model show that fishing vessels would experience the most frequent rate of incidents, accounting for nearly all of the collisions, at 0.7325 per year.

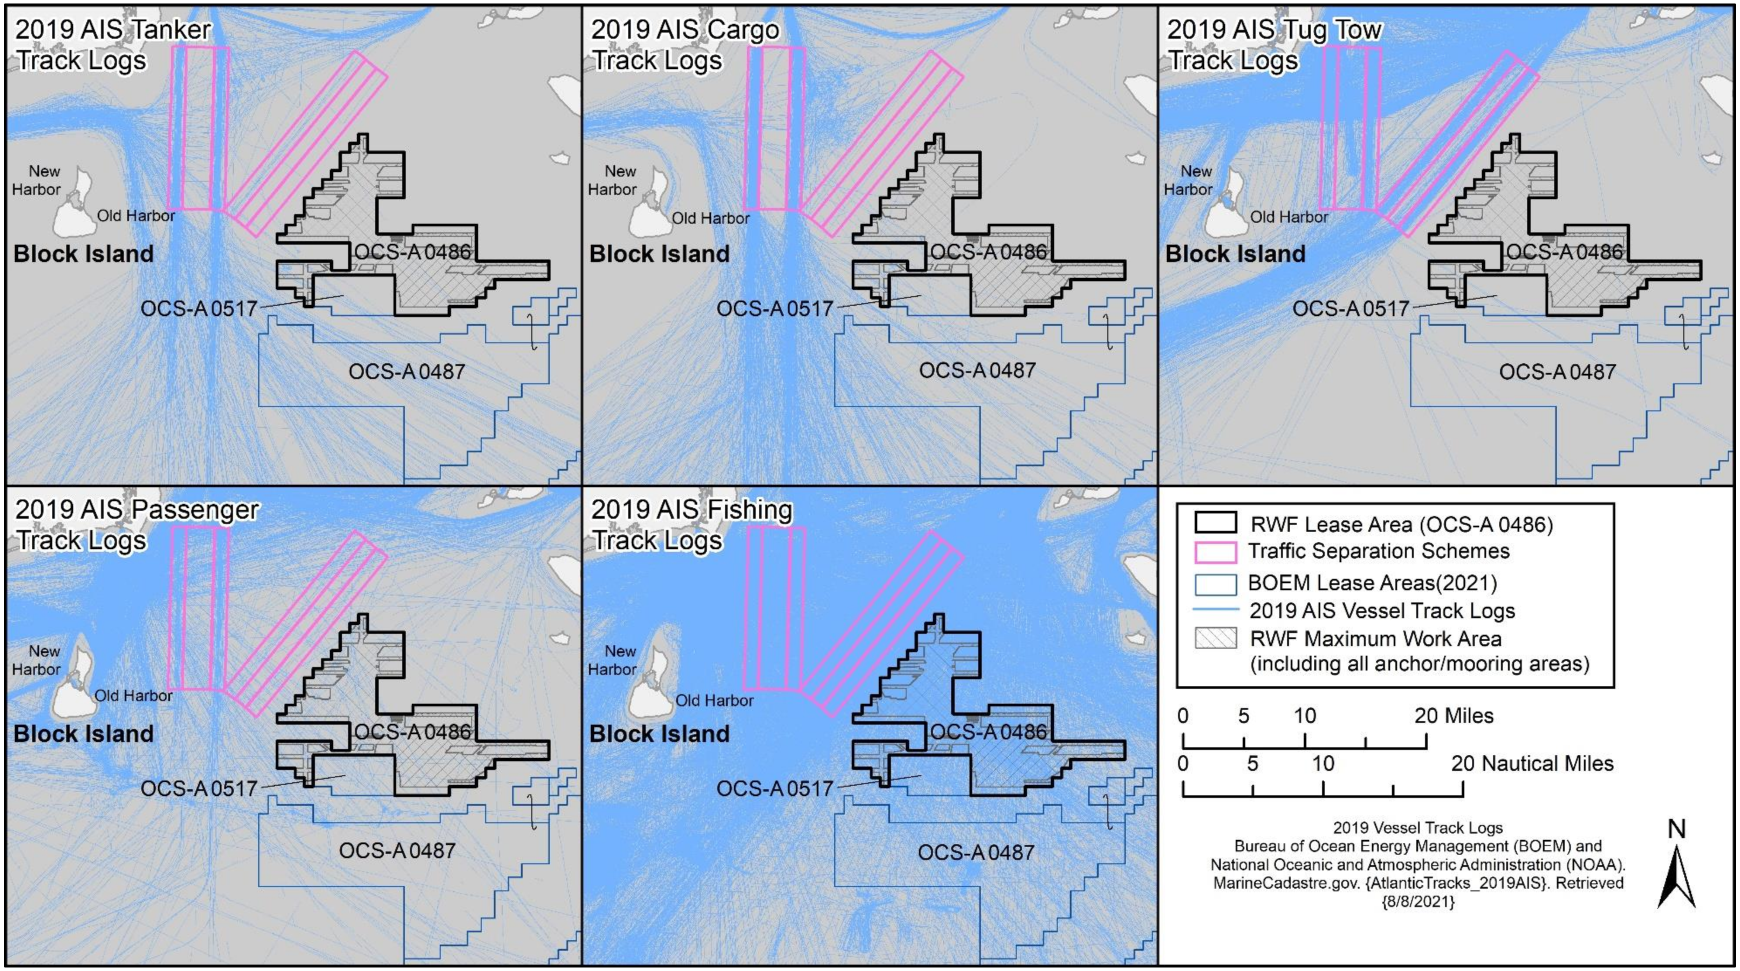

**Figure 3.16-2. Vessel traffic near the Lease Area.**

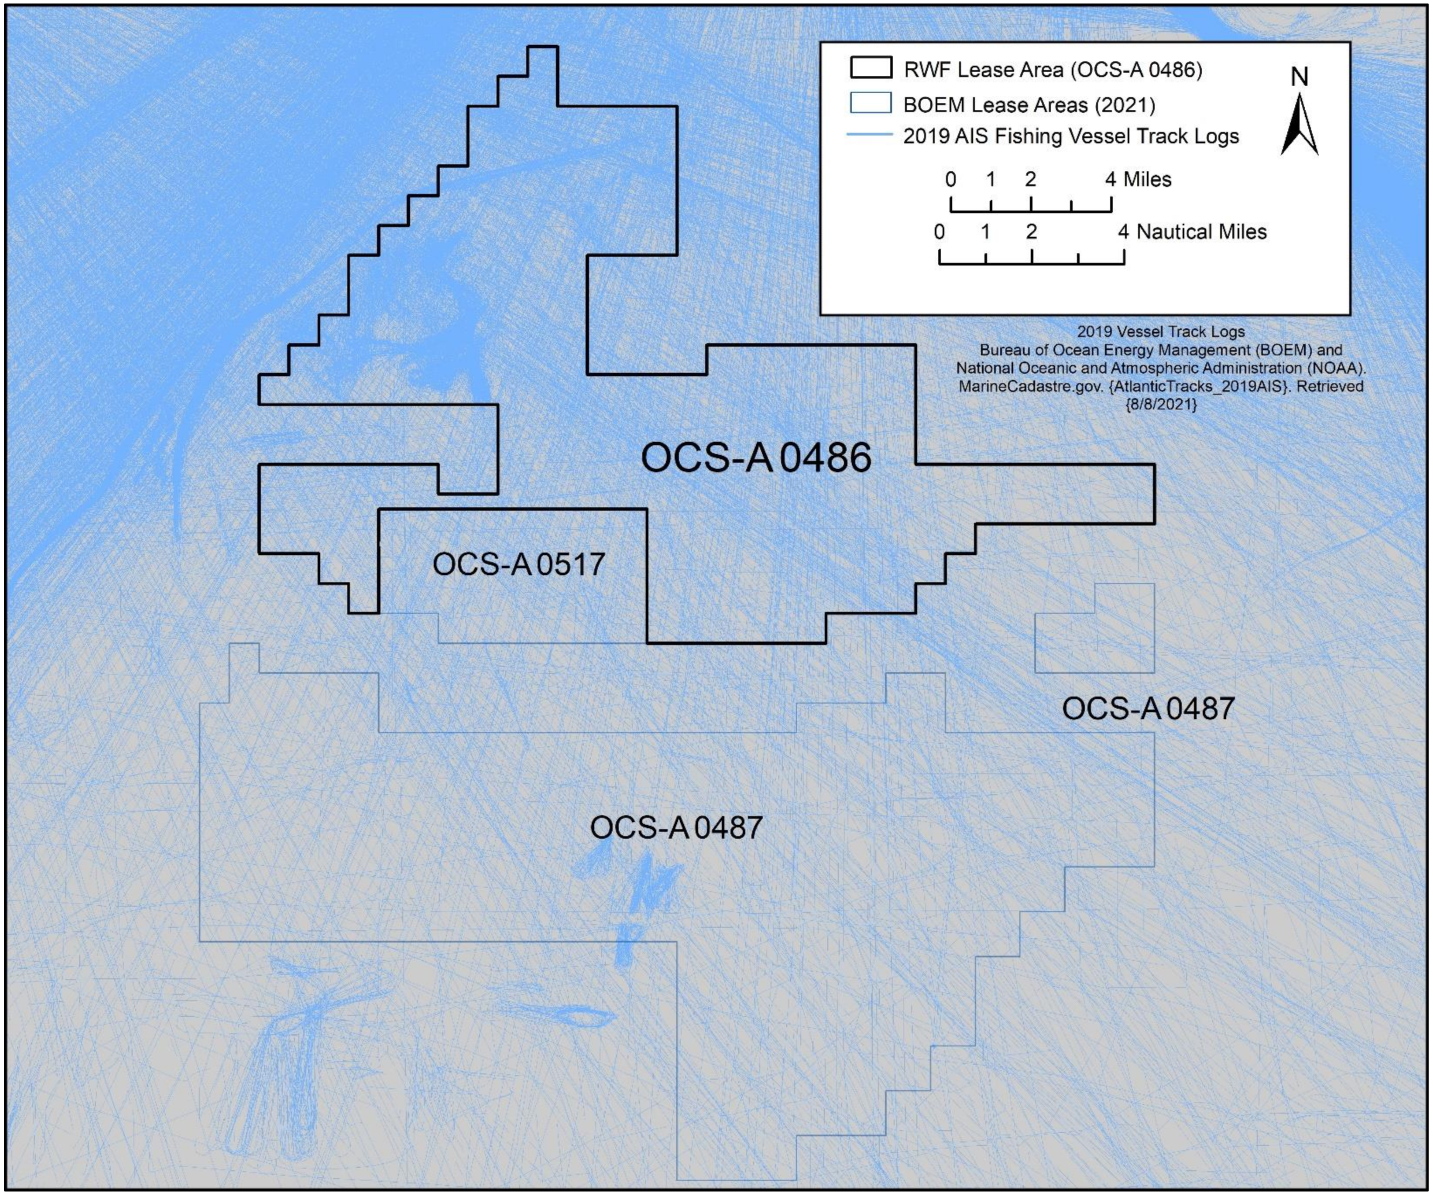

**Figure 3.16-3. Detail of fishing vessel traffic near the Lease Area.**

## 3.16.2 Environmental Consequences

### 3.16.2.1 Relevant Design Parameters, Impact-Producing Factors, and Potential Variances in Impacts

This assessment analyzes the maximum-case scenario; however, there is the potential for variances in the proposed Project build-out, as defined in the PDE (see Appendix D). If Revolution Wind implements a less impactful scenario within the PDE, smaller amounts of construction or infrastructure development would result in lower impacts but would not likely result in different impact ratings than those described below.

The relevant design parameters for impacts to navigation and vessel traffic are the number and layout of WTGs and OSSs (i.e., the presence of structures) within the Lease Area. If the number of structures is reduced, the change in impact would be based on the location of the WTGs removed. Removal of rows or columns of structures would have the greatest change in impacts due to the increased navigation space created. Removal of select structures not organized in rows or columns would have less of an impact due to the navigational constraints and layout of the remaining grid pattern. Changes to the layout that move away from a standard 1 × 1–nm grid would increase the navigational complexity and the risk of incidents, including collisions, allisions, and accidental releases.

See Appendix E1 for a summary of IPFs analyzed for navigation and vessel traffic across all action alternatives. IPFs that are either not applicable to the resource or determined by BOEM to have a negligible effect are excluded from Chapter 3 and provided in Table E2-13 in Appendix E1.

Table 3.16-3 provides a comparison of all evaluated IPFs for navigation and vessel traffic across alternatives. Each alternative analysis discussion consists of the construction and installation phase, the O&M phase, the decommissioning phase, and the cumulative analysis. If these analyses are not substantially different, then they are presented as one discussion. Detailed analysis of other considered action alternatives is also provided below the table if analysis indicates that the alternative(s) would result in substantially different impacts than the Proposed Action. Offshore and onshore IPFs are addressed separately in the analysis if appropriate for the resource; not all IPFs have both an offshore and onshore component.

The conclusion section within each alternative analysis discussion includes rationale for the overall effect call determination.

Under all of the options overall impact to navigation and vessel traffic from any alternative would be long term **moderate** adverse, as impacts would be notable, but the resource would recover completely when the impacting agents are removed and remedial or mitigating actions are taken. Where feasible, calculations for specific alternative impacts are provided in Appendix E4, to facilitate reader comparison across alternatives.

*This page intentionally left blank.*

**Table 3.16-3. Alternative Comparison Summary for Navigation and Vessel Traffic**

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTG | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative G (Preferred Alternative) | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|---|---|
| Anchoring and new cable emplacement/ maintenance | **Offshore**: Anchoring vessels used in the construction of offshore wind energy projects would pose a navigational hazard to vessels. Although anchoring impacts would occur primarily during Project construction, some impacts could also occur during O&M and decommissioning. All impacts would be localized (within a few hundred yards of an anchored vessel) and temporary (hours to days). Impacts on navigation and vessel traffic would be temporary localized **minor** adverse, and navigation and vessel traffic would fully recover following the disturbance.<br>Offshore cable emplacement would have temporary localized **minor** adverse impacts on boating because vessels would need to navigate around work areas, and some boaters would prefer to avoid the noise and disruption caused by installation. | **Offshore**: The Project would have no impact on ordinary anchoring activity in the area. The Project may have some impact on anchoring near the cable route, provided that a vessel might need to anchor in an emergency. Cable laying would have a temporary **negligible** to **minor** adverse impact on vessels entering or exiting commercial shipping lanes and the precautionary area during construction. Impacts of anchoring and new cable emplacement/maintenance on deep draft vessels during operations would be long term **negligible** adverse.<br>BOEM estimates a total of 25,019 acres of cabling- and anchoring-related seafloor disturbance for the Proposed Action plus all other future offshore wind projects in the contiguous RI/MA and MA WEA lease areas. Therefore, when considered in combination with past, present, and other reasonably foreseeable projects, the Project would have short-term **minor** to **moderate** adverse cumulative impacts on navigation and vessel traffic. | **Offshore**: Alternatives C through F would reduce the IAC proportionally based on the number of WTGs but would still require cables to connect the extent of the WTGs. The construction impacts from anchoring and new cable emplacement/maintenance would be similar to the Proposed Action. Ordinary anchoring activity would occur outside the Lease Area and not be affected. When combining any of the action alternatives (C–F) with the Proposed Action, anchoring and new cable emplacement/maintenance impacts during construction and installation could be slightly reduced. However, this reduction would not result in a change in the overall impact conclusion when compared to that alternative by itself. Overall, there would be a temporary **negligible** to **minor** adverse impact on vessels entering or exiting commercial shipping lanes and the precautionary area from cable laying and a temporary **moderate** adverse impact on commercial fishing vessels.<br>During operation, as with the Proposed Action, the Project would have no impact on ordinary vessel anchorage operations, although risks would still exist for emergency anchoring and vessels transiting the area at a reduced level due to the smaller footprints. Impacts of anchoring and new cable emplacement/maintenance on deep draft vessels during operations would be long term **negligible** adverse.<br>The alternatives would contribute to the cumulative impacts of offshore wind projects but to a lesser extent than the Proposed Action based on the alternative chosen. The change from Alternatives C through F would be negligible relative to all future activity in the contiguous RI/MA and MA WEA lease areas and it is unexpected that Project cable installation would overlap with other project cable routes. When considered in combination with past, present, and other reasonably foreseeable projects the Project would have short-term **minor** to **moderate** adverse cumulative impacts on navigation and vessel traffic. | | | | **Offshore**: Alternative G's construction impacts from anchoring and new cable emplacement/maintenance would be similar to the Proposed Action. Ordinary anchoring activity would occur outside the Lease Area and not be affected. Anchoring and new cable emplacement/maintenance impacts during construction and installation could be slightly reduced, though this would not result in a change in the overall impact conclusion. Overall, there would be a temporary **negligible** to **minor** adverse impact on vessels entering or exiting commercial shipping lanes and the precautionary area from cable laying, and a temporary **moderate** adverse impact on commercial fishing vessels.<br>During operation, as with the Proposed Action, the Project would have no impact on ordinary vessel anchorage operations, although risks would still exist for emergency anchoring and vessels transiting the area at a reduced level. Impacts of anchoring and new cable emplacement/maintenance on deep draft vessels during operations would be long term **negligible** adverse.<br>The alternatives would contribute to the cumulative impacts of offshore wind projects but to a lesser extent than the Proposed Action. The change would be negligible relative to all future activity in the contiguous RI/MA and MA WEA lease areas, and it is not expected that Project cable installation would overlap with other project cable routes. When considered in combination with past, present, and other reasonably foreseeable projects, the Project would have short-term **minor** to **moderate** adverse cumulative impacts on navigation and vessel traffic. |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action)<br>up to 100 WTG | Alternative C<br>(Habitat Alternative)<br>64–65 WTGs | Alternative G<br>(Preferred Alternative) | Alternative E<br>(Viewshed Alternative)<br>64–81 WTGs | Alternative F<br>(Higher Capacity Turbine Alternative)<br>56 WTGs | Alternative G<br>(Preferred Alternative) |
|---|---|---|---|---|---|---|---|
| Port utilization | **Offshore**: Construction and operation of improvements at various ports in support of reasonably foreseeable offshore wind projects could coincide with the forecasted port improvements listed in Appendix E, some of which are intended to directly support offshore wind energy development. Port improvements could increase vessel congestion and stress port capacity during construction, leading to temporary localized **minor** to **moderate** adverse impacts based on how the different projects manage their port utilization. | **Offshore**: Because of the small number of vessels involved with Project construction, any ports potentially used by these vessels would be able to accommodate their needs at existing facilities without significant modifications or upgrades; therefore, the impact to port operations or port congestion would be temporary **negligible** to **minor** adverse.<br>Any ports used by vessels conducting maintenance would have a long-term **negligible** adverse impact because ports potentially used by these vessels would be able to accommodate their needs at existing facilities without significant modifications or upgrades.<br>Project port activity and upgrades (via dredging and in-water work) could coincide with other forecasted projects. Port activities could be delayed or ports could experience congestion or changes in utilization as a result of the overlap in construction activities. Therefore, the cumulative impacts of the Proposed Action when combined with past, present, and reasonably foreseeable future projects would have long-lasting overall but temporary impacts on specific ports (depending on how each project manages its port utilization) with localized **minor** to **moderate** adverse impacts on port utilization. | **Offshore**: Alternatives C through F would reduce the number and duration of vessel activity. Therefore, construction impacts on port utilization would be reduced from the levels of the Proposed Action depending on the alternative chosen, but still temporary **negligible** adverse.<br>Alternatives C through F would reduce the number and duration of vessels working on maintenance activity, although due to the vessels primarily working on-site, the change to port utilization would be negligible. Ports potentially used by these vessels would be able to accommodate their needs at existing facilities without significant modifications or upgrades. Therefore, Alternative C through F would have the same impact from port utilization as the Proposed Action: long term **negligible** adverse.<br>Port upgrades and vessel activity associated with the Project could result in negligible impacts to navigation and vessel traffic. Alternatives C through F would require fewer construction vessels than the Proposed Action and would therefore reduce the potential impact on ports, reducing its share of cumulative impacts, depending on the alternative chosen. However, port activity and upgrades (via dredging and in-water work) could coincide with other forecasted projects, and a reduced footprint relative to the Proposed Action would not likely have much of an impact overall. The cumulative impacts of Alternatives C through F when combined with past, present, and reasonably foreseeable future projects would have long-lasting overall but temporary impacts on specific ports (depending on how each project manages its port utilization), with localized **minor** to **moderate** adverse impacts on port utilization. | | | | **Offshore**: Alternative G would reduce the number and duration of vessel activity. Therefore, construction impacts on port utilization would be reduced from the levels of the Proposed Action, but would still be temporary **negligible** adverse.<br>The alternative would also reduce the number and duration of vessels working on maintenance activity, although due to the vessels primarily working on-site, the change to port utilization would be negligible. Ports potentially used by these vessels would be able to accommodate their needs at existing facilities without significant modifications or upgrades. Therefore, Alternative G would have the same impact from port utilization as the Proposed Action: long term **negligible** adverse.<br>Port upgrades and vessel activity associated with the Project could result in negligible impacts to navigation and vessel traffic. Alternative G would require fewer construction vessels than the Proposed Action and would therefore reduce the potential impact on ports, reducing its share of cumulative impacts, depending on the alternative chosen. However, port activity and upgrades (via dredging and in-water work) could coincide with other forecasted projects, and a reduced footprint relative to the Proposed Action would not likely have much of an impact overall. The cumulative impact of Alternative G when combined with past, present, and reasonably foreseeable future projects would have long-lasting overall but temporary impacts on specific ports (depending on how each project manages its port utilization), with localized **minor** to **moderate** adverse impacts on port utilization. |
| Presence of structures | **Offshore**: Using the assumptions in Appendix E4, the No Action Alternative would include 81 foundations, with a cumulative total of 1,025 foundations. The | **Offshore**: Revolution Wind would develop a mariner communication plan, limit construction activities to periods of good weather, and request the USCG implement temporary safety zones | **Offshore**: As with the Proposed Action, Revolution Wind would develop a mariner communication plan, limit construction activities to periods of good weather conditions, and request the USCG implement temporary safety zones around the locations with active construction. In addition to the reduced footprint, depending on the option(s) chosen, this | | | | **Offshore**: As with the Proposed Action, Revolution Wind would request the USCG implement temporary safety zones around the locations with active |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTG | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative G (Preferred Alternative) | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|---|---|
| | placement of these structures in the contiguous RI/MA WEA and MA WEA lease areas would have long-term **negligible** to **moderate** adverse impacts on vessels through the risk of allision, navigation hazards, space-use conflicts, the presence of cable infrastructure, and visual impacts. | around the locations with active construction. This would minimize impacts from offshore RWEC construction. The impact would be temporary and increase from **negligible** to **moderate** adverse as structures are added.<br>For vessels that generally travel within and through the Lease Area, a vessel's view could be obstructed for as much as 7.8 seconds. Because of the 1 × 1–nm spacing of the Project structures, the impact on visibility would be further reduced. The Project would use USCG-approved lighting to make nearby vessels aware of structure locations (see Appendix F for EPMs). The structures would not impact a mariner's ability to use navigation aids or the coastline as a reference for navigation. Overall, spacing and placement of the structures would result in a long-term **negligible** adverse impact to visibility and a long-term **moderate** adverse impact from the presence of structures due to increased navigational complexity and allision risk.<br>The Proposed Action would add up to 100 additional WTGs and two OSSs to the No Action Alternative's 1,015 cumulative structures, which would increase navigational complexity and therefore the risk of collision, allision, and potential spills. Additional structures could also interfere with marine radars and aircraft engaging in search and rescue efforts. The Proposed Action would more than double the number of existing structures, though it would account for 10% of the total future structures in the contiguous RI/MA and MA WEA lease areas and would implement a 1 × 1–nm uniform north–south and east–west grid spacing, consistent with other contiguous RI/MA and MA WEA lease areas. The cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would consist predominantly of impacts described under the No Action Alternative, which would represent a long-term **moderate** adverse impact on navigation and vessel traffic. | would minimize impacts from offshore RWEC construction (see Appendix F). Due to controls in the working area, Alternatives C through F would have impacts slightly reduced but similar to the Proposed Action for the presence of structures: temporary and increasing from **negligible** to **moderate** adverse as structures are added.<br>The removal of structures from the northern and northwestern sections of the Lease Area under Alternative E would, in particular, move construction activity away from areas with the greatest commercial fishing activity, resulting in a temporary impact on commercial fishing vessel navigation that would increase from **negligible** to **minor** adverse as structures are added during construction. Fishing activity would see the greatest reduction in impacts relative to the Proposed Action.<br>During operations, Alternatives C through F would reduce the number of WTGs in the Lease Area, which would alleviate some navigational complexity in areas where WTGs are not present. Detailed analysis is provided in Section 3.16.2.3.<br>Alternatives C through F would add to the 81 structures present under the No Action Alternative and 1,025 total cumulative structures including future offshore wind energy projects, which would increase navigational complexity; increase the risk of collision, allision, and potential spills; and potentially interfere with marine radar or aircraft conducting search and rescue efforts. See Section 3.17 (Other Uses) for a discussion of potential impacts to search and rescue efforts. The footprint of each alternative would have varying impacts on these activities based on other actions. Detailed analysis is provided in Section 3.16.2.3. | | | | construction, develop a mariner communication plan, and limit construction activities to periods of good weather conditions. In addition to the reduced footprint, this would minimize impacts from offshore RWEC construction (see Appendix F). Due to controls in the working area, Alternative G would have impacts slightly reduced but similar to the Proposed Action for the presence of structures: temporary and increasing from **negligible** to **moderate** adverse as structures are added.<br>The removal of structures from the southwest section of the Lease Area would move construction activity away from areas with some commercial fishing traffic, resulting in a temporary impact on commercial fishing vessel navigation that would increase from **negligible** to **minor** adverse as structures are added during construction. Fishing activity would see a small reduction in impacts relative to the Proposed Action.<br>During operations, Alternative G would reduce the number of WTGs in the Lease Area relative to the Proposed Action, which would alleviate some navigational complexity in areas where WTGs are not present, resulting in long term **minor** to **moderate** adverse impacts. Detailed analysis is provided in Section 3.16.2.3.<br>The alternative would add to the 81 structures present under the No Action Alternative, which would increase navigational complexity; increase the risk of collision, allision, and potential spills; and potentially interfere with marine radar or aircraft conducting search and rescue efforts. |---|---|---|---|---|---|---|---|
| | | | | | | | The cumulative impacts associated with the Preferred Action would be similar to that of the Proposed Action: long term **moderate** adverse on navigation and vessel traffic. |
| Vessel traffic | **Offshore**: Vessel activity could peak in 2025, with as many as 210 vessels involved in the construction and operation of current and reasonably foreseeable projects (see Table 3.16-4). Construction activities would result in increased vessel traffic near the lease areas and ports used as well as obstructions to navigation and changes to navigation patterns. Additional impacts would include delays within or approaching ports; increased navigational complexity; detours to offshore travel or port approaches; or increased risk of incidents such as collision, strikes or allisions, and groundings.<br>As a whole, this level of traffic activity would represent a long-term overall but temporary **minor** to **moderate** adverse impact on individual ports and a **minor** to **moderate** adverse impact to navigation under the No Action Alternative because the construction would be located outside major shipping lanes and the number of vessels would be small compared to the overall level of traffic near each of the potential developments. The vessels impacted under this alternative would be primarily commercial fishing and other types of vessels that have historically transited to and operated within or near each of the potential developments. | **Offshore**: Project effects on navigation and vessel traffic would include increased vessel traffic near the RWF, offshore RWEC, and ports used by the Project; obstructions to navigation; delays within or approaching ports; increased navigational complexity; changes to navigation patterns; detours to offshore travel or port approaches; or increased risk of incidents such as allisions. There would be a short-term **minor** adverse impact on deep draft, tug, and towing vessels and commercial fishing vessels would experience temporary **moderate** adverse impacts. Because of the small number of vessels involved in construction, Project construction would have a temporary (for the duration of construction activities) **negligible** adverse impact on commercial traffic as a whole.<br>Maintenance would have a long-term **negligible to minor** adverse impact on navigation and vessel traffic because of the infrequent nature of monitoring and inspection. Maintenance would primarily impact commercial fishing and other vessels operating at the same time and place that maintenance is performed. Because of the low frequency of allision and collision incidents and Project EPMs, the expected risks to navigation would be long term **negligible** adverse. Decommissioning of the Project would have similar short-term (for the duration of decommissioning activities) **minor** to **moderate** adverse impacts as construction.<br>The Proposed Action would add as many as 56 construction vessels during construction in 2024 and 2025 to conditions under the No Action Alternative. BOEM estimates a peak of 259 vessels at sea on a daily basis due to offshore wind Project construction and O&M over a 10-year time frame, with most of these vessels remaining in the vicinity of their respective lease areas. Therefore, cumulative impacts associated with the Project when combined with past, present, | **Offshore**: As with the Proposed Action, Project construction could impact navigation and vessel traffic. Project effects on navigation and vessel traffic would include increased vessel traffic near the RWF, offshore RWEC, and ports used by the Project; obstructions to navigation; delays within or approaching ports; increased navigational complexity; changes to navigation patterns; detours to offshore travel or port approaches; or increased risk of incidents such as allisions. These impacts would be reduced proportionally with the smaller footprint on the chosen alternative due to a smaller area under construction.<br>Alternatives D3 and E2 have a reduced potential for affecting vessel traffic by extending the buffer around and moving construction away from the traffic separation scheme. Likewise, the combinations of D1+D3 and D1+D2+D3 would have reduced potential for affecting vessel traffic.<br>Construction of offshore components of the Project under Alternatives C through F would likely require less time than anticipated for the Proposed Action (see COP Section 3.2). The NSRA indicates the highest risk would be from smaller non-Project vessels operating close to construction and work vessels; this risk would be reduced based on the smaller footprint (DNV GL Energy USA, Inc. 2020). There would be a temporary (for the duration of construction activities) minor adverse impact on smaller vessels, which would need to reroute around the Project. Commercial fishing vessels would experience temporary moderate adverse impacts. However, because of the small number of vessels involved in construction and due to controls in the working area, Project construction would have a temporary (for the duration of construction activities) **negligible** adverse impact on commercial traffic as a whole.<br>Operational impacts to navigation would be reduced from the Proposed Action in vessel traffic, though not meaningfully so, due to the decreased footprint of Alternatives C through F and removal of structures from the trafficked areas. All alternatives would still be located within the Lease Area and would primarily affect vessels that normally would be present, in particular, fishing vessels. Most vessel transits would take place outside the Lease Area; impacts due to the presence of structures are addressed above. Overall, the net effect is that Alternatives C through F would have the same impact from vessel traffic as the Proposed Action: long term **negligible** adverse. Decommissioning of the Project under Alternatives C through F would have similar short-term (for the duration of decommissioning activities) **minor** to **moderate** adverse impacts as construction because decommissioning would use similar numbers of vessels and implement the same EPMs. After the Project is decommissioned, the navigation conditions in the area would return to pre-Project conditions pursuant to 30 CFR 585.910.<br>Alternatives C through F would add construction vessels in 2024 and 2025 to conditions under the No Action Alternative at a level proportionally lower than the maximum-case scenario under the Proposed Action based on the alternative chosen. Non-Project traffic would largely avoid the work area and transiting construction vessels, with potentially fewer adjustments needed based on the vessels' routes and the reduced work area. Project O&M vessel traffic under Alternatives C through F would be less than that of the Proposed Action. When compared to all future activities considered in this analysis, these reductions in the Project's impact would cause a meaningful reduction in cumulative impacts. The reduction would to some extent depend on the actions taken by other future activities. Alternative D1, for example, would result in less of a | | | | **Offshore**: As with the Proposed Action, Project construction could impact navigation and vessel traffic. Project effects on navigation and vessel traffic would include increased vessel traffic near the RWF, offshore RWEC, and ports used by the Project; obstructions to navigation; delays within or approaching ports; increased navigational complexity; changes to navigation patterns; detours to offshore travel or port approaches; or increased risk of incidents such as allisions. These impacts would be reduced proportionally with the smaller footprint on the chosen alternative due to a smaller area under construction.<br>Alternative G would have a slightly reduced potential for affecting vessel traffic by eliminating WTGs in the southwest portion of the Lease Area.<br>Construction of offshore components of the Project would likely require less time than anticipated for the Proposed Action. The NSRA indicates the highest risk would be from smaller non-Project vessels operating close to construction and work vessels; this risk would be reduced based on the smaller footprint (DNV GL Energy USA, Inc. 2020). There would be a temporary (for the duration of construction activities) **minor** adverse impact on smaller vessels, which would need to reroute around the Project. Commercial fishing vessels would experience temporary **moderate** adverse impacts. However, because of the small number of vessels involved in construction and due to controls in the working area, Project construction would have a temporary (for the duration of |

### 3.16.2.2 Alternative A: Impacts of the No Action Alternative on Navigation and Vessel Traffic

#### 3.16.2.2.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for navigation and vessel traffic (see Section 3.16.1) would continue to follow current regional trends and respond to IPFs introduced by other ongoing activities and by permitted and constructed offshore wind COP projects within the geographic analysis area. These IPFs are described and analyzed in Appendix E1.

#### 3.16.2.2.2 Cumulative Impacts

This section discloses potential cumulative navigation impacts associated with future offshore wind development (without the Proposed Action). The cumulative impact analysis for the No Action Alternative for planned non-offshore wind activities, as well as activities associated with constructed or approved offshore wind projects (without the Proposed Action), is provided in Appendix E1.

<u>Anchoring and new cable emplacement/maintenance:</u> BOEM estimates approximately 3,848 acres of seafloor would be disturbed by anchoring associated with offshore wind activities. Anchoring vessels used in the construction of offshore wind energy projects would pose a navigational hazard to vessels. Although anchoring impacts would occur primarily during Project construction, some impacts could also occur during O&M and decommissioning. All impacts would be localized (within a few hundred yards of an anchored vessel) and temporary (hours to days). Therefore, the effects of offshore wind energy–related anchoring on commercial fisheries and for-hire recreational fishing are expected to be short term **minor** adverse.

Future offshore wind developers are expected to coordinate with the maritime community and the USCG to avoid laying export cables through any traditional or designated lightering/anchorage areas, meaning that any risk for deep draft vessels would come from anchoring in an emergency scenario, specifically in or near the Buzzards Bay and Narragansett Bay traffic separation schemes. Generally, larger vessels accidently dropping anchor on top of an export cable (buried or mattress protected) to prevent drifting in the event of vessel power failure would result in damage to the export cable, risks to the vessel associated with an anchor contacting an electrified cable, and impacts to the vessel operator’s liability and insurance. Impacts on navigation and vessel traffic would be temporary localized **minor** adverse, and navigation and vessel traffic would fully recover following the disturbance.

Under the No Action Alternative, up to 2,952 miles of cable could be installed in the contiguous RI/MA WEA and Massachusetts Wind Energy Area (MA WEA) lease areas to support future offshore wind projects (see Figure 1.1-2 for location of RI/MA and MA WEAs). Offshore cable emplacement would have temporary localized **minor** adverse impacts on boating because vessels would need to navigate around work areas, and some boaters would prefer to avoid the noise and disruption caused by installation.

<u>Port utilization:</u> Construction and operation of improvements at various ports in support of reasonably foreseeable offshore wind projects could coincide with the forecasted port improvements listed in Appendix E, some of which are intended to directly support offshore wind energy development. Port improvements could increase vessel congestion and stress port capacity during construction, leading to temporary localized **minor** to **moderate** adverse impacts based on how the different projects manage

their port utilization. However, state and local agencies would be responsible for minimizing the potential adverse impacts of additional port utilization by managing traffic to ensure continued access to ports.

Presence of structures: Using the assumptions in Appendix E3, future offshore wind energy projects under the No Action Alternative would include 1,015 foundations. The placement of these structures in the contiguous RI/MA WEA and MA WEA lease areas would have long-term adverse impacts on vessels through the risk of allision, navigation hazards, space-use conflicts, the presence of cable infrastructure, and visual impacts. While lease areas are generally located in low vessel traffic areas, they do receive some use. Table 3.16-1 summarizes the miles traveled by vessels within the Lease Area and other lease areas in 2019.

The presence of offshore wind structures would increase the GAA's navigational complexity, thereby increasing the risk of allision or collision. Deep draft, tug, and towing vessels would need to minimally divert to avoid traveling near structures. Vessels that generally travel within and through lease areas could require an adjustment of navigation practices. The attraction of artificial reef effects would increase vessel congestion and the risk of allision, collision, and spills near structures. BOEM assumes that all offshore wind developments in the GAA would use the developer-agreed-upon 1 × 1–nm spacing in fixed east–west rows and north–south columns and would evaluate each of those individual projects in their respective NEPA analyses. Because this layout supports traditional east–west active fishing operations, this arrangement would reduce, but not eliminate, navigational complexity and space-use conflicts during the operations phases of the projects.

Vessel traffic: Applying vessel activity estimates developed by BOEM based on its 2019 study *National Environmental Policy Act Documentation for Impact-Producing Factors in the Offshore Wind Cumulative Impacts Scenario on the North Atlantic Outer Continental Shelf* (BOEM 2019) and applying construction vessel activity estimates presented in *Vineyard Wind I Offshore Wind Energy Project Final Environmental Impact Statement Volume I* (BOEM 2021), if construction of the Project does not occur, vessel activity could peak in 2025, with as many as 210 vessels involved in the construction and operation of current and reasonably foreseeable projects (Table 3.16-4).

**Table 3.16-4. Cumulative Construction and Operations Vessels from Current and Future Activities**

| Vessels | 2021 | 2022 | 2023 | 2024 | 2025 | 2026 | 2027 |
|---|---|---|---|---|---|---|---|
| Average construction vessels | 1 | 0 | 72 | 106 | 102 | 16 | 0 |
| Maximum construction vessels | 1 | 0 | 132 | 194 | 188 | 28 | 0 |
| Average operations vessels | 1 | 1 | 1 | 3 | 8 | 12 | 12 |
| Maximum operations vessels | 1 | 1 | 1 | 9 | 22 | 34 | 36 |
| Average daily vessels, total | 2 | 1 | 73 | 109 | 110 | 28 | 12 |
| Maximum daily vessels, total | 2 | 1 | 133 | 203 | 210 | 62 | 36 |

Source: Developed using offshore wind projects listed in Table E-1 in Appendix E and estimates of average (maximum) daily vessels per foundation of 0.245 (0.451) for construction and 0.010 (0.029) for operations from BOEM (2021).

Construction activities would result in increased vessel traffic near the lease areas and ports used as well as obstructions to navigation and changes to navigation patterns. Additional impacts would include delays within or approaching ports; increased navigational complexity; detours to offshore travel or port approaches; or increased risk of incidents such as collision, strikes or allisions, and groundings. Other reasonably foreseeable future offshore projects would produce additional vessel traffic during construction, but because of their timing, they are not anticipated to use the same traffic routes. Construction of other offshore wind projects are anticipated to be scheduled to minimize overlapping construction periods and reduce the number of construction vessels in operation at any given time, effectively reducing the cumulative impact on port congestion and construction vessel rerouting. As a whole, this level of traffic activity would represent a long-term overall but temporary **minor** to **moderate** adverse impact on individual ports and a **minor** to **moderate** adverse impact to navigation under the No Action Alternative because the construction would be located outside major shipping lanes and the number of vessels would be small compared to the overall level of traffic near each of the potential developments.

Cumulative impacts during O&M of reasonably foreseeable offshore wind projects (see Table 3.16-3) would also represent a long-term **negligible** to **minor** adverse impact to navigation due to the smaller number of vessels and lower frequency of activities (growing to an average of 12 vessel trips per day by 2027). Decommissioning of each of the projects is anticipated to have cumulative impacts similar to those experienced during construction. All reasonably foreseeable offshore wind projects would be required to prepare an NSRA in compliance with the guidelines in USCG NVIC 01-19 (USCG 2019), which would serve to minimize impacts to marine navigation.

#### 3.16.2.2.3 Conclusions

Under the No Action Alternative, BOEM would not approve the COP; Project construction and installation, O&M, and decommissioning would not occur; and potential impacts on navigation associated with the Project would not occur. However, ongoing and future activities would have continuing temporary to long-term **minor** to **moderate** impacts on navigation, primarily through existing traffic activity, port use, and the presence of structures.

BOEM anticipates that the range of impacts for reasonably foreseeable offshore wind activities, especially the presence of structures, port utilization, and vessel traffic, would be long term minor to moderate adverse. As described in Appendix E1, BOEM anticipates that the range of impacts for ongoing activities and reasonably foreseeable activities other than offshore wind would also be long term minor to moderate adverse. Future projects would increase vessel activity, which could lead to congestion at affected ports, the possible need for port upgrades beyond those currently envisioned, and an increased likelihood of collisions and allisions, with a resultant increased risk of accidental releases. In addition, the presence of new structures would also increase the risk for collisions, allisions, and resultant accidental releases and threats to human health and safety.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the GAA combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in long-term **minor** to **moderate** adverse impacts because the overall effect would be notable, but vessels would be able to adjust to account for disruptions and EPMs would reduce impacts.

### 3.16.2.3 Alternative B: Impacts of the Proposed Action on Navigation and Vessel Traffic

#### 3.16.2.3.1 Construction and Installation

#### Offshore Activities and Facilities

Anchoring and new cable emplacement/maintenance: The nearest anchorage area is 6.7 nm from the Project (DNV GL Energy USA, Inc. 2020:Section 2.2.2.5), and the Project would have no impact on ordinary anchoring activity in the area. The Project may have some impact on anchoring near the cable route, provided that a vessel might need to anchor in an emergency. Cable laying would have a temporary **negligible** to **minor** adverse impact on vessels entering or exiting commercial shipping lanes and the precautionary area.

Port utilization: Because of the small number of vessels involved with Project construction, any ports potentially used by these vessels would be able to accommodate their needs at existing facilities without significant modifications or upgrades; therefore, the impact to port operations would be temporary **negligible** to **minor** adverse. See Section 3.11 for a list of potential port facilities the Project could use and how they would be used. There would be a temporary **negligible** to **minor** adverse impact on port congestion.

Presence of structures: Revolution Wind would develop a mariner communication plan, limit construction activities to periods of good weather conditions, and request the USCG implement temporary safety zones around the locations with active construction (see Table F-1 in Appendix F). This would minimize impacts from offshore RWEC construction, though the addition of 100 structures would more than double the 81 structures under the No Action Alternative. The impact would be temporary and increase from **negligible** to **moderate** adverse as structures are added.

Vessel traffic: Project construction could impact navigation and vessel traffic. Project effects on navigation and vessel traffic would include increased vessel traffic near the RWF, offshore RWEC, and ports used by the Project; obstructions to navigation; delays within or approaching ports; increased navigational complexity; changes to navigation patterns; detours to offshore travel or port approaches; or increased risk of incidents such as allisions.

Construction of offshore components of the Project would require approximately 8 months for the RWEC, 5 months for WTG foundations, 5 months for the IAC, 8 months for WTGs, and 8 months for OSSs (see Chapter 2, Figure 2.1-9). The NSRA indicates the highest risk would be from smaller non-Project vessels operating close to construction and work vessels. Because of the small number of vessels used for construction and the location of the Project outside shipping lanes (see Figures 3.16-2 and 3.16-3), there would be a short-term (for the duration of construction activities) **minor** adverse impact on deep draft, tug, and towing vessels, which would need to reroute around the Project for a slightly longer route, and smaller passenger vessels, which could reroute closer to shore, increasing grounding potential. During construction and installation, commercial fishing vessels would need to avoid work areas and could be adversely impacted, depending on the location of the exploitable biomass and whether there are suitable alternative locations; with respect to navigation, commercial fishing vessels would experience temporary **moderate** adverse impacts. Because of the small number of vessels involved in construction, Project construction would have a temporary (for the duration of construction activities) **negligible** adverse impact on commercial traffic as a whole.

#### 3.16.2.3.2 Operations and Maintenance and Decommissioning

### Offshore Activities and Facilities

<u>Anchoring and new cable emplacement/maintenance:</u> The nearest anchorage area is 6.7 nm away from the Project (DNV GL Energy USA, Inc. 2020:Section 2.2.2.5), and the Project would have no impact to ordinary vessel anchorage operations, although risks would still exist for emergency anchoring and vessels transiting the area. Impacts of anchoring and new cable emplacement/maintenance on deep draft vessels during operations would be long term **negligible** adverse.

<u>Port utilization:</u> Any ports used by vessels conducting maintenance would have a long-term **negligible** adverse impact because ports potentially used by these vessels would be able to accommodate their needs at existing facilities without significant modifications or upgrades.

<u>Presence of structures:</u> For vessels that generally travel within and through the Lease Area, the NSRA mapped out the placement of the structures and evaluated the time of potential visual obstruction each would present based on a vessel's speed (DNV GL Energy USA, Inc. 2020:Section 9). At a speed of 5 knots, a vessel's view could be obstructed for as much as 7.8 seconds. The NSRA notes that this is a conservative estimate because it reflects the view of a single moving vessel and not multiple moving vessels that would enhance each vessel's ability to see the others. Because of the 1 × 1–nm spacing of the Project structures, the impact on visibility would be further reduced. The Project would use USCG-approved lighting to make nearby vessels aware of structure locations (see Appendix F for EPMs). The structures would not impact a mariner's ability to use navigation aids or the coastline as a reference for navigation. Overall, spacing and placement of the structures would result in a long-term **negligible** adverse impact to visibility. NOAA also would identify and chart the structures and offshore RWEC.

Under the Proposed Action, there is a modeled increase of 1.4 incidents per year in the NSRA's study area over baseline conditions as a result of changes to travel patterns to certain vessel types (DNV GL Energy USA, Inc. 2020:Table 11-2). More than 99% of total incidents would be allisions, and 92% of total incidents would involve fishing vessels. Based on the NSRA results, there would be a negligible increase (0.004) in collisions.

The Project calls for a standard and uniform grid pattern with 1-nm spacing between structures (WTGs and OSSs) across the contiguous RI/MA and MA WEA lease areas, which provides sufficient space for certain vessels that fish in the RI/MA and MA WEAs to continue fishing after the wind farms are constructed. See Figure 1.1-2 for location of the RI/MA and MA WEAs. The USCG has determined that if structures are developed along a standard and uniform grid pattern, formal or informal vessel routing measures would not be required because such a grid pattern would provide space for dispersal of the fleet that can safely accommodate both transits through and fishing within the RI/MA and MA WEAs. The USCG believes the 1 × 1–nm aligned and gridded layout should be sufficient to maintain navigational safety and provide vessels with multiple straight-line options to transit safely throughout the contiguous RI/MA and MA WEA lease areas (USCG 2020). Marine vessel radars are not optimized to operate in a WTG environment due to a combination of factors ranging from the slow adoption of solid-state technology to the electromagnetic characteristics of WTGs (National Academies of Sciences, Engineering, and Medicine 2022). USCG also noted in its final *The Areas Offshore of Massachusetts and Rhode Island Port Access Route Study* (USCG 2020) that various factors play a role in potential marine radar interference by offshore wind infrastructure, stating that "the potential for interference with marine radar is site specific and depends on many factors including, but not limited to, turbine size, array layouts, number of turbines, construction material(s), and the vessel types." It is anticipated that industry will adopt both technological and non-technological-based measures to reduce impacts on marine radar, including greater use of AIS and electronic charting systems, use of new technologies like LiDAR, employing more watchstanders, and avoiding wind farms altogether.

The USCG has reviewed all available studies on radar interference and found that although these studies show that structures could have some effect upon radar, as discussed in the MARIPARS report, they do not render radar inoperable and do not inform planning decisions about structure arrangement or spacing (USCG 2020).

Overall, as the number of structures increases from 81 under the No Action Alternative to 181 structures under the Proposed Action, there would be a long-term **moderate** adverse impact from the presence of structures due to increased navigational complexity and allision risk.

<u>Vessel traffic:</u> During operations, maintenance is expected on a periodic basis for each offshore component (offshore transmission facilities, WTG and OSS foundations, and WTGs) (see COP Sections 3.5.2 through 3.5.4). This limited operation activity would have a long-term **negligible to minor** adverse impact on navigation and vessel traffic, with impacts primarily on commercial fishing and other vessels operating at the same time and place as maintenance vessels.

Because of the low frequency of allision and collision incidents and Project EPMs (see Table F-1 in Appendix F), the expected risks to navigation would be long term **negligible** adverse. Most deep draft vessel traffic already avoids the area and would not need to meaningfully reroute, as shown in Figures 3.16-2 and 3.16-3. The Project is outside existing traffic lanes and is not expected to require significant rerouting of traffic to avoid Project components (DNV GL Energy USA, Inc. 2020:Table 5-1).

Impacts to traffic from offshore RWEC maintenance would be temporary **negligible** adverse because of the infrequent nature of monitoring and inspection. Decommissioning of the Project would have similar short-term (for the duration of decommissioning activities) **minor** to **moderate** adverse impacts as construction because decommissioning would use similar numbers of vessels and implement the same EPMs. After the facility is decommissioned, the navigation conditions in the area would return to pre-Project conditions.

#### 3.16.2.3.3 Cumulative Impacts

### Offshore Activities and Facilities

<u>Anchoring and new cable emplacement/maintenance:</u> The Proposed Action would add up to 7,213 acres of seafloor disturbance from RWEC, OSS-link, IAC installation, and anchoring/mooring activity to the seafloor cable–related disturbance estimated under the No Action Alternative. This would result in localized temporary **minor** adverse cumulative impacts on navigation and vessel traffic due to increased collision and spill risk during construction. BOEM estimates a total of 25,019 acres of seafloor disturbance for the Proposed Action plus all other future offshore wind projects in the GAA. During installation and maintenance, other vessels could also be forced to reroute to avoid installation and maintenance vessels. Cable installation for the Project is not expected to overlap with other project cable routes or installation based on the location of other offshore wind projects and proposed construction schedules (see Appendix E). Therefore, when considered in combination with past, present, and other

reasonably foreseeable projects, the Project would have short-term **minor** to **moderate** adverse cumulative impacts on navigation and vessel traffic.

Port utilization: Port upgrades and vessel activity associated with the Proposed Action could result in negligible impacts to navigation and vessel traffic. The Proposed Action is expected to require as many as 56 construction vessels during construction in 2024 (primarily) and 2025 (see COP Table 3.3.10-2 and COP Figure 3.2-1). There would be 1,400 vessel return trips (see COP Table 3.3.10-2), although most vessels would be concentrated in the work area, with fewer vessels transporting crew and materials back and forth from ports. This additional vessel traffic could cause delays or changes in berthing patterns at primary ports. It could lead to operators being redirected to use alternate ports or facilities on a temporary basis. To some extent, individual ports could independently undertake facility improvement projects in anticipation of this demand to relieve some of the potential congestion. The Project's impact on port capacity would also be limited due to the small number of additional vessels.

Project port activity and upgrades (via dredging and in-water work) could coincide with other forecasted projects. Port activities could be delayed or ports could experience congestion or changes in utilization as a result of the overlap in construction activities. Therefore, the cumulative impacts of the Proposed Action when combined with past, present, and reasonably foreseeable future projects would have long-lasting overall but temporary impacts on specific ports (depending on how each project manages its port utilization) with localized **minor** to **moderate** adverse impacts on port utilization.

Presence of structures: The Proposed Action would add up to 100 additional WTGs and two OSSs to the 1,015 structures present under the No Action Alternative, which would increase navigational complexity and therefore the risk of collision, allision, and potential spills. Additional structures could also interfere with marine radars and aircraft engaging in search and rescue efforts. See Table 3.16-1 for a summary of miles traveled by vessels carrying AIS within the Lease Area and other lease areas in 2019. The commercial fisheries discussion in Appendix G presents VMS numbers for commercial fishing vessels. The Proposed Action would account for 10% of the total future structures in the GAA; however, Revolution Wind would implement a 1 × 1–nm uniform north–south and east–west grid spacing, consistent with other contiguous RI/MA and MA WEA lease areas. Therefore, the Project would contribute a long-term **moderate** adverse impact from the presence of structures due to increased navigational complexity and allision risk. The cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would consist predominantly of impacts described under the No Action Alternative, which would represent a long-term **moderate** adverse impact on navigation and vessel traffic.

Vessel traffic: The Proposed Action would add as many as 56 construction vessels during construction in 2024 and 2025 to conditions under the No Action Alternative (see COP Table 3.3.10-2). The Proposed Action represents up to 22% of the total maximum vessels potentially present in 2024. Non-Project traffic would be able to adjust routes and avoid the work area and transiting construction vessels. Project O&M vessel traffic would be substantially less because the RWF would represent 10% of the WTGs in service by 2027 under the No Action Alternative, all of which are assumed to have similar O&M vessel traffic generation. Therefore, the Proposed Action would result in a **minor** adverse impact to vessel traffic. BOEM estimates a peak of 259 vessels at sea on a daily basis due to offshore wind Project construction and O&M over a 10-year time frame, with most of these vessels remaining in the vicinity of their respective lease areas. Therefore, cumulative impacts associated with the Project when combined with past, present, and reasonably foreseeable future activities would be short term **minor** adverse.

#### 3.16.2.3.4 Conclusions

Project construction and installation, O&M, and decommissioning would impact navigation and vessel traffic, primarily through increased traffic; obstructions to navigation; delays within or approaching ports; increased navigational complexity; changes to navigation patterns; detours to offshore travel or port approaches; or increased risk of incidents such as collision, strikes, or allisions, and groundings. BOEM anticipates the impacts resulting from the Proposed Action alone would be long term **moderate** adverse. Therefore, BOEM expects the overall impact on navigation from the Proposed Action alone to be long term **moderate** adverse.

In the context of other reasonably foreseeable environmental trends and planned actions, the impacts under the Proposed Action resulting from individual IPFs would range from temporary to long term **negligible** to **moderate** adverse. The main IPF of concern is the presence of structures, which increase navigational complexity and therefore the risk of collision/allision. Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in long-term **moderate** adverse impacts to navigation. The overall effect to navigation and vessel traffic would be notable, but the resource would recover completely when the impacting agents are removed and remedial or mitigating actions are taken.

### 3.16.2.4 Alternatives C, D, E, and F

#### 3.16.2.4.1 Operations and Maintenance and Decommissioning

##### Offshore Activities and Facilities

<u>Presence of structures:</u> The Habitat Alternative would reduce the number of WTGs in the central area of the Lease Area, which would alleviate some navigational complexity around that area, where WTGs are not present. However, the presence of an OSS in the center of the area that would otherwise be clear of WTGs (under both C1 and C2) would introduce some complexity, and the presence of three WTGs to the northeast of the OSS (under C2) would create further complexity. Further, the presence of structures in the adjacent OCS-A 0517 lease area could create navigational issues. Overall, the net effect is that Alternative C (under both C1 and C2) would have a slightly reduced impact from the presence of structures from the Proposed Action: long term **minor** to **moderate** adverse.

For the Transit Alternative, Alternative D1 would result in a long-term **moderate** adverse impact from the increased navigational complexity and allision risk. Alternative D2 would result in a long-term **minor** to **moderate** adverse impact from the increased navigational complexity and allision risk, specifically reducing impacts on the fishing and passenger vessels that transit through this area, as it would remove an “ungrouped” section of structures, making navigation through this area more predictable. Alternative D3 would result in a long-term **minor** to **moderate** adverse impact from the presence of structures due to the increased navigational complexity and allision risk. Alternative D3 would result in a somewhat reduced impact from the Proposed Action (although not enough to change the impact rating), as it would remove structures adjacent to the inbound lane of the Buzzards Bay Traffic Separation Scheme that fall within the USCG’s Marine Planning Guidelines buffers (USCG 2019). This would reduce risks specifically to commercial and international vessels (e.g., deep draft cargo and tanker). Alternatives D1+D2, D1+D3, and D1+D2+D3 would have a long-term **minor** to **moderate** adverse impact from the presence of structures.

For the Viewshed Alternative, Alternative E2 would expand the traffic separation scheme buffer from 1 nm to 2 nm, reducing the potential for conflict with vessel traffic. Overall, spacing and placement of the structures would result in a long-term **minor** to **moderate** adverse impact to visibility, although navigational complexity would increase from the concentration of traffic in the open area and increase the likelihood that fishing activities will occur there. This could lead to conflicting uses and, accordingly, increased risk of allision/collision. Removal of structures under this alternative would primarily affect commercial fishing vessels, which are active in the area. Alternatives E1 and E2 would reduce impacts to fishing vessels and would result in a long-term **minor** adverse impact to fishing vessel navigation from the presence of structures due to the increased allision risk.

For the Higher Capacity Turbine Alternative, the presence of structures impacts during operations and maintenance and decommissioning could be slightly reduced but similar to the Proposed Action (long term **moderate** adverse) depending on the alternative (C, D, or E) chosen and the location(s) of foundations affected by the reduction.

#### 3.16.2.4.2 Cumulative Impacts

### Offshore Activities and Facilities

Presence of structures: The Habitat Alternative would create an apparent passage through the middle of the Lease Area along a northeast–southwest route, which could encourage traffic to transit through that area. Therefore, Alternative C (under both C1 and C2) would have the same cumulative impact from presence of structures as the Proposed Action: long term **moderate** adverse.

For the Transit Alternative, under Alternative D1, the fishing industry–proposed transit lane intersects four contiguous BOEM lease areas: OCS-A 0486 (RWF), OCS-A 0487, OCS-A 0500, and OCS-A 0517.[47] If a similar east–west opening were to be incorporated into the selected alternatives for proposed wind energy projects in the OCS-A 0487, OCS-A 0500, and OCS-A 0517 lease areas, it would reduce the number of structures but may also increase navigational complexity by concentrating traffic in the open area and increasing the likelihood that fishing activities will occur there. This could lead to conflicting uses and, accordingly, increased risk of allision/collision, resulting in a long-term moderate adverse impact on navigation. However, if any of those other lease areas are approved with wind energy project configurations that do not incorporate a similar opening, Alternative D1 would increase the navigational complexity and may result in a long-term **moderate** adverse impact on navigation.

Under Alternative D2, the fishing industry–proposed transit lane intersects four contiguous BOEM lease areas: OCS-A 0486, OCS-A 0487, OCS-A 0500, and OCS-A 0501.[48] Under this alternative, the easternmost reach of the RWF Lease Area would be open for vessel traffic. If the selected alternatives for proposed wind energy projects in the OCS-A 0487, OCS-A 0500, and OCS-A 0501 lease areas to the south of this section were to adopt a similar transit alternative to allow north–south traffic, it would reduce the number of structures but may also increase navigational complexity by concentrating traffic in

[47] Note that OCS-A 0517 is part of the No Action Alternative.
[48] Note that OCS-A 0501 is part of the No Action Alternative.

the open area and increasing the likelihood that fishing activities will occur there. This could lead to conflicting uses and, accordingly, increased risk of allision/collision, resulting in a cumulative long-term to moderate adverse impact on navigation. If the other projects were to develop structures that preclude north–south transit, the cumulative impact on navigation would be long term **moderate** adverse.

Under Alternative D3, the setback proposed would intersect only the OCS-A 0486 Lease Area (RWF). Under this alternative, the lack of structures along the northwestern edge of the Lease Area would extend the traffic separation scheme buffer from 1 nm to 2 nm. No other RI/MA and MA WEA lease areas would be affected by this change, resulting in a long-term **moderate** adverse cumulative impact to navigation.

Combining alternatives would result in combined effects. It would reduce the number of structures but may also increase navigational complexity by concentrating traffic in the open area and increasing the likelihood that fishing activities will occur there. This could lead to conflicting uses and, accordingly, increased risk of allision/collision, Alternatives D1+D2, D1+D3, and D1+D2+D3 would result in long-term **moderate** adverse cumulative impacts.

For the Viewshed Alternative, structures removed by this alternative relative to the Proposed Action are positioned away from other lease areas and would not cause additional interactions with structures in those other areas. As a result, the cumulative impact of each of the Alternative E layouts would be long term **minor** adverse to navigation.

Under the Higher Capacity Turbine Alternative, presence of structures impacts from cumulative activities could be slightly reduced but similar to the Proposed Action (long term **moderate** adverse) depending on the alternative (C, D, or E) chosen and the location(s) of foundations affected by the reduction.

#### 3.16.2.4.3 Conclusions

Although these alternatives would reduce the number of WTGs when compared to the maximum-case scenario under the Proposed Action and, in turn, the associated IACs and vessel activity, Alternatives C through F would maintain uniform north–south and east–west grid spacing and separation of 1 nm. Therefore, BOEM expects that the impacts resulting from each alternative alone would be similar to the Proposed Action: long term **moderate** adverse.

In the context of other future actions, BOEM expects the alternative’s impacts would depend on development in nearby lease areas. Alternative C would add sources of navigation impacts (e.g., structures, noise, port utilization) to the No Action Alternative at quantities and durations similar to the Proposed Action. Therefore, the overall impact on navigation and vessel traffic when combined with past, present, and reasonably foreseeable activities would be the same as under the Proposed Action: long term intermittent **moderate** adverse.

Alternative D could reduce impacts to **minor** to **moderate** adverse if other lease areas likewise limit development to create an east–west area that is open to traffic. However, if the other lease areas were to develop fully, the impacts of each Alternative D scenario when combined with other future activities would be the same level as the Proposed Action: long term **moderate** adverse.

For Alternative E, the locations where structures would be eliminated would not interact with development in other lease areas. Therefore, BOEM expects Alternative E’s impacts would be long term **minor** to **moderate** adverse.

For Alternative F, the locations where structures would be eliminated cannot be determined. Depending on those locations, the Project could or could not interact with development in other lease areas. Therefore, BOEM expects Alternative F's impacts would be similar to that of the Proposed Action (long term **moderate** adverse) depending on the alternative (C, D, or E) chosen.

### 3.16.2.5 Alternative G: Impacts of the Preferred Alternative on Navigation and Vessel Traffic

#### 3.16.2.5.1 Operations and Maintenance and Decommissioning

##### Offshore Activities and Facilities

Presence of structures: Alternative G would avoid placement of WTGs in the southwest section of the Lease Area as well as in numerous central locations. The avoidance of the southwest section could alleviate some navigational complexity around that area, though it would not have an impact on transiting vessels due to the presence of WTGs to the north of this area and the adjacent SFWF (OCS-A 0517). Alternative G would avoid an area used by some fishing vessels, as shown in Figure 3.16-3. The removal of WTGs in central locations would not affect transits but could affect vessels operating within the Lease Area. From a navigation and vessel traffic perspective, Alternatives G, G1, G2, and G3 would have similar impacts, slightly reduced from the Proposed Action: long term **minor** to **moderate** adverse.

#### 3.16.2.5.2 Cumulative Impacts

##### Offshore Activities and Facilities

Presence of structures: Under Alternative G, impacts from the presence of structures could be slightly reduced but similar to the Proposed Action (long term **moderate** adverse) due to other wind lease areas south of the Lease Area. Although the removal of WTGs would open the southwest section of the Lease Area to vessels, the other lease areas would prevent vessels from transiting in that area.

#### 3.16.2.5.3 Conclusions

Although Alternative G would reduce the number of WTGs when compared to the Proposed Action, it would maintain its uniform north–south and east–west grid spacing and separation of 1 nm. It would eliminate WTGs in the southwest section of the Lease Area, but that impact would be mitigated by the presence of the SFWF (OCS-A 0517). Therefore, BOEM expects that the impacts resulting from Alternative G would be slightly reduced from the Proposed Action: long term **minor** to **moderate** adverse.

In the context of other future actions, the presence of additional wind lease areas to the south would result in impacts similar to that of the Proposed Action: long term **moderate** adverse.

### 3.16.2.6 Mitigation

Mitigation measures resulting from agency consultations for navigation and vessel traffic are identified in Appendix F, Table F-2, and addressed in Table 3.16-5.

**Table 3.16-5. Mitigation and Monitoring Measures Resulting from Consultations for Navigation and Vessel Traffic (Appendix F, Table F-2)**

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| Submarine cable system burial plan | Revolution Wind shall submit a copy of the submarine cable system burial plan as part of their facility design report and fabrication and installation report that depicts precise planned locations and burial depths of the entire cable system. | This measure would not modify the impact determinations for navigation and vessel traffic but would ensure that these effects do not exceed the levels analyzed herein. |
| Boulder relocation reporting | The locations of any boulder (which would protrude > 2 meters or more on the seafloor) relocated during cable installation activities must be reported to BOEM, USCG, NOAA, and the local harbormaster. These locations must be reported in latitude and longitude degrees to the nearest 10 thousandth of a decimal degree (roughly the nearest meter), or as precise as practicable. | This measure would not modify the impact determinations for navigation and vessel traffic but would ensure that these effects do not exceed the levels analyzed herein. |
| Vessel safety practices | All Project vessels involved in construction, O&M, and decommissioning activities would comply with U.S. or international Safety of Life at Sea standards, as applicable, with regard to vessel construction, vessel safety equipment, and crewing practices. | This measure would not modify the impact determinations for navigation and vessel traffic but would ensure that these effects do not exceed the levels analyzed herein. |
| WTG and OSS marking | Each WTG and OSS would be marked with private aids to navigation (PATONs), subject to the approval of the Commander (dpw-1), First Coast Guard District. Revolution Wind would do the following:<br>Provide BOEM and USCG with a proposed lighting, marking, and signaling plan, which must be approved by BOEM after consultation with the USCG. The plan should conform to the International Association of Marine Aids to Navigation and Lighthouse Authorities Recommendation G1162, The Marking of Man-Made Offshore Structures. Should any part of the recommendation conflict with federal law or regulation, or if SFW seeks an alternative to the recommendation, Revolution Wind must consult with the USCG.<br>Mark each individual WTG and OSS with clearly visible, unique, alphanumeric identification characters.<br>Light each WTG and OSS in a manner that is visible by mariners in a 360-degree arc around the WTG and OSS.<br>Apply to the First Coast Guard District to establish PATONs for the facility. Approval for all PATONs must be obtained before installation of the Revolution Wind structures begins. | This measure would not modify the impact determinations for navigation and vessel traffic but would ensure that these effects do not exceed the levels analyzed herein. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | Ensure each WTG is lighted with red obstruction lighting consistent with the FAA Advisory Circular 70/7460-1L Change 2 (FAA 2018), so long as this requirement does not preclude the use of an ADLS.<br>Provide signage that covers 360-degrees of the wind turbine structures warning vessels of the air draft of the turbine blades as determined at highest astronomical tide.<br>Cooperate with USCG and NOAA to ensure that cable routes and wind turbines are depicted on appropriate government produced and commercially available nautical charts.<br>Provide mariner information sheets on Revolution Wind's website with details on the location of the turbines and specifics such as blade clearance above sea level. | |
| WTG shut-down mechanism | Equip all WTG rotors (blade assemblies) with control mechanisms operable from the Revolution Wind control centers available 24 hours a day, 7 days a week. The control mechanisms shall enable control room operators to shut down the requested WTGs within an agreed upon time of notification between the USCG and Revolution Wind. A formal shut-down procedure would be part of the standard operating procedures and periodically tested. Normally, USCG-ordered shut downs would be limited to those WTGs in the immediate vicinity of an emergency and for as short a period as is safely practicable under the circumstances, as determined by the USCG. | This measure would not modify the impact determinations for navigation and vessel traffic but would ensure that these effects do not exceed the levels analyzed herein. |
| USCG training and exercises | Revolution Wind would participate in periodic USCG-coordinated training and exercises to test and refine notification and shut-down procedures and to provide SAR training opportunities for USCG vessels and aircraft. | This measure would not modify the impact determinations for navigation and vessel traffic but would ensure that these effects do not exceed the levels analyzed herein. |
| Operations and maintenance plan | Prior to operation of the Project, Revolution Wind shall submit a written plan for operations and maintenance, which includes control center(s), for review by BOEM and the USCG. The plan must demonstrate that the control center(s) would be adequately staffed to perform standard operating procedures, communications capabilities, and monitoring capabilities. The plan shall include the following topics, which may be modified through ongoing discussions with the USCG: | This measure would not modify the impact determinations for navigation and vessel traffic but would ensure that these effects do not exceed the levels analyzed herein. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | Standard operating procedures: Methods for establishing and testing WTG rotor shut-down; methods of lighting control; method(s) for notifying the USCG of mariners in distress or potential/actual SAR incidents; method(s) for notifying the USCG of any events or incidents that may impact maritime safety or security; and methods for providing the USCG with environmental data, imagery, communications and other information pertinent to SAR or marine pollution response.<br>Staffing: Number of personnel intended to staff the control center(s) to ensure continuous monitoring of WTG operations, communications, and surveillance systems.<br>Communications: Capabilities to be maintained by the control center(s) to communicate with the USCG and mariners within and in the vicinity of the Project area. Communications capability shall at a minimum include VHF marine radio and landline and wireless for voice and data.<br>Monitoring: The control center(s) should maintain the capability to monitor the Project's installation and operations in real time (including night and periods of poor visibility) for determining the status of all PATONs, and to detect any survivor who has climbed to the survivor’s platform, if installed, on any WTG or OSS. | |
| WTG/OSS installation | No WTG/OSS installation work will begin in the Lease Area (i.e., on or under the water) without prior review by BOEM and USCG of a plan submitted by Revolution Wind that describes the schedule and process for erecting each WTG, including all planned mitigations to be implemented to minimize any adverse impacts on navigation while installation is ongoing. Appropriate Notice to Mariners submissions would accompany the plan. | This measure would not modify the impact determinations for navigation and vessel traffic but would ensure that these effects do not exceed the levels analyzed herein. |
| USCG reporting | Complaints: On a monthly basis during installation, Revolution Wind shall provide USCG with a description of any complaints received (either written or oral) by boaters, fishermen, commercial vessel operators, or other mariners regarding impacts on navigation safety allegedly caused by construction vessels, crew transfer vessels, barges, or other equipment. Describe any remedial action taken in response to complaints received. | This measure would not modify the impact determinations for navigation and vessel traffic but would ensure that these effects do not exceed the levels analyzed herein. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | Correspondence: Revolution Wind shall provide to USCG copies of any correspondence received by Revolution Wind from other federal, state, or local agencies that mention or address navigation safety issues.<br>Maintenance: Revolution Wind would provide the USCG with its planned WTG maintenance schedule, forecasted out to at least one quarter. Appropriate Notice to Mariners submissions would accompany each maintenance schedule. | |
| Public participation | To ensure sufficient opportunity for the public to receive information directly from the owners/operators of the wind energy facility, Revolution Wind would attend periodic meetings of the Southeastern Massachusetts and Rhode Island Port Safety and Security Forums to provide briefs on the status of construction and operations and on any problems or issues encountered with respect to navigation safety. | This measure would not modify the impact determinations for navigation and vessel traffic but would ensure that these effects do not exceed the levels analyzed herein. |
| Helicopter landing platforms | If Revolution Wind's OSSs include helicopter-landing platforms, those platforms would be designed and built to accommodate up to and including USCG H-60-sized rescue helicopters. | This measure would not modify the impact determinations for navigation and vessel traffic but would ensure that these effects do not exceed the levels analyzed herein. |

#### 3.16.2.6.1 Measures Incorporated into the Preferred Alternative

Mitigation measures required through completed consultations, authorizations, and permits listed in Table 3.16-5 and in Appendix F, Table F-2, are incorporated into Alternative G (Preferred Alternative). These measures, if adopted, would further define how the effectiveness and enforcement of EPMs would be ensured and improve accountability for compliance with EPMs by requiring the submittal of plans for approval by the enforcing agency(ies) and by defining reporting requirements. Because these measures ensure the effectiveness of and compliance with EPMs that are already analyzed as part of the Proposed Action, implementation of these measures would not further reduce the impact level of the Proposed Action from what is described in Section 3.16.2. Agency-proposed measures related to vessel speed restrictions would expand upon Revolution Wind's EPMs to require that all vessels regardless of size would comply with speed restrictions in any seasonal management area, dynamic management area, or slow zone. Although adoption of these measures would reduce risk to marine mammals (see Section 3.15) and sea turtles (see Section 3.19) under the Proposed Action, it would not alter the impact determinations for navigation and vessel traffic.

# 3.17 Other Marine Uses

## 3.17.1 Description of the Affected Environment for Other Marine Uses

Geographic analysis area: The GAA for other marine uses: scientific research and surveys includes the footprint of the Proposed Action and all reasonably foreseeable projects between Maine and mid-North Carolina (Figure 3.17-1). This area encompasses locations where scientific research and surveys are anticipated.

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of GAAs for additional other marine uses categories analyzed in the EIS (aviation and air traffic, land-based radar, military and national security, and undersea cables).

### 3.17.1.1 Aviation and Air Traffic

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to aviation and air traffic from implementation of the Proposed Action and other considered alternatives.

### 3.17.1.2 Land-Based Radar

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to land-based radar from implementation of the Proposed Action and other considered alternatives.

### 3.17.1.3 Military and National Security

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to military and national security from implementation of the Proposed Action and other considered alternatives.

### 3.17.1.4 Scientific Research and Surveys

Affected environment: Government-managed fisheries surveys, both state and federal, occur within the region at varying times of year. As an example, through the Ecosystems Surveys Branch, NOAA Fisheries collects fishery-independent data using standardized research vessel surveys from Cape Hatteras, North Carolina, to the Scotian shelf. These data are used for assessment, management, and a variety of research programs (NOAA Fisheries 2018). NOAA Fisheries' seasonal survey locations vary and are randomly selected and stratified by depth. BOEM and NOAA have developed a federal survey mitigation strategy for the northeast U.S. region that addresses potential impacts of offshore wind energy development on NOAA Fisheries' scientific surveys (Hare et al. 2022). Because of the depths and acreage in the region, there is a likelihood of sample survey locations being placed within the RWF and waters along the RWEC. It is likely that other surveys conducted by academic institutions and non-governmental organizations occur within the region (VHB 2023).

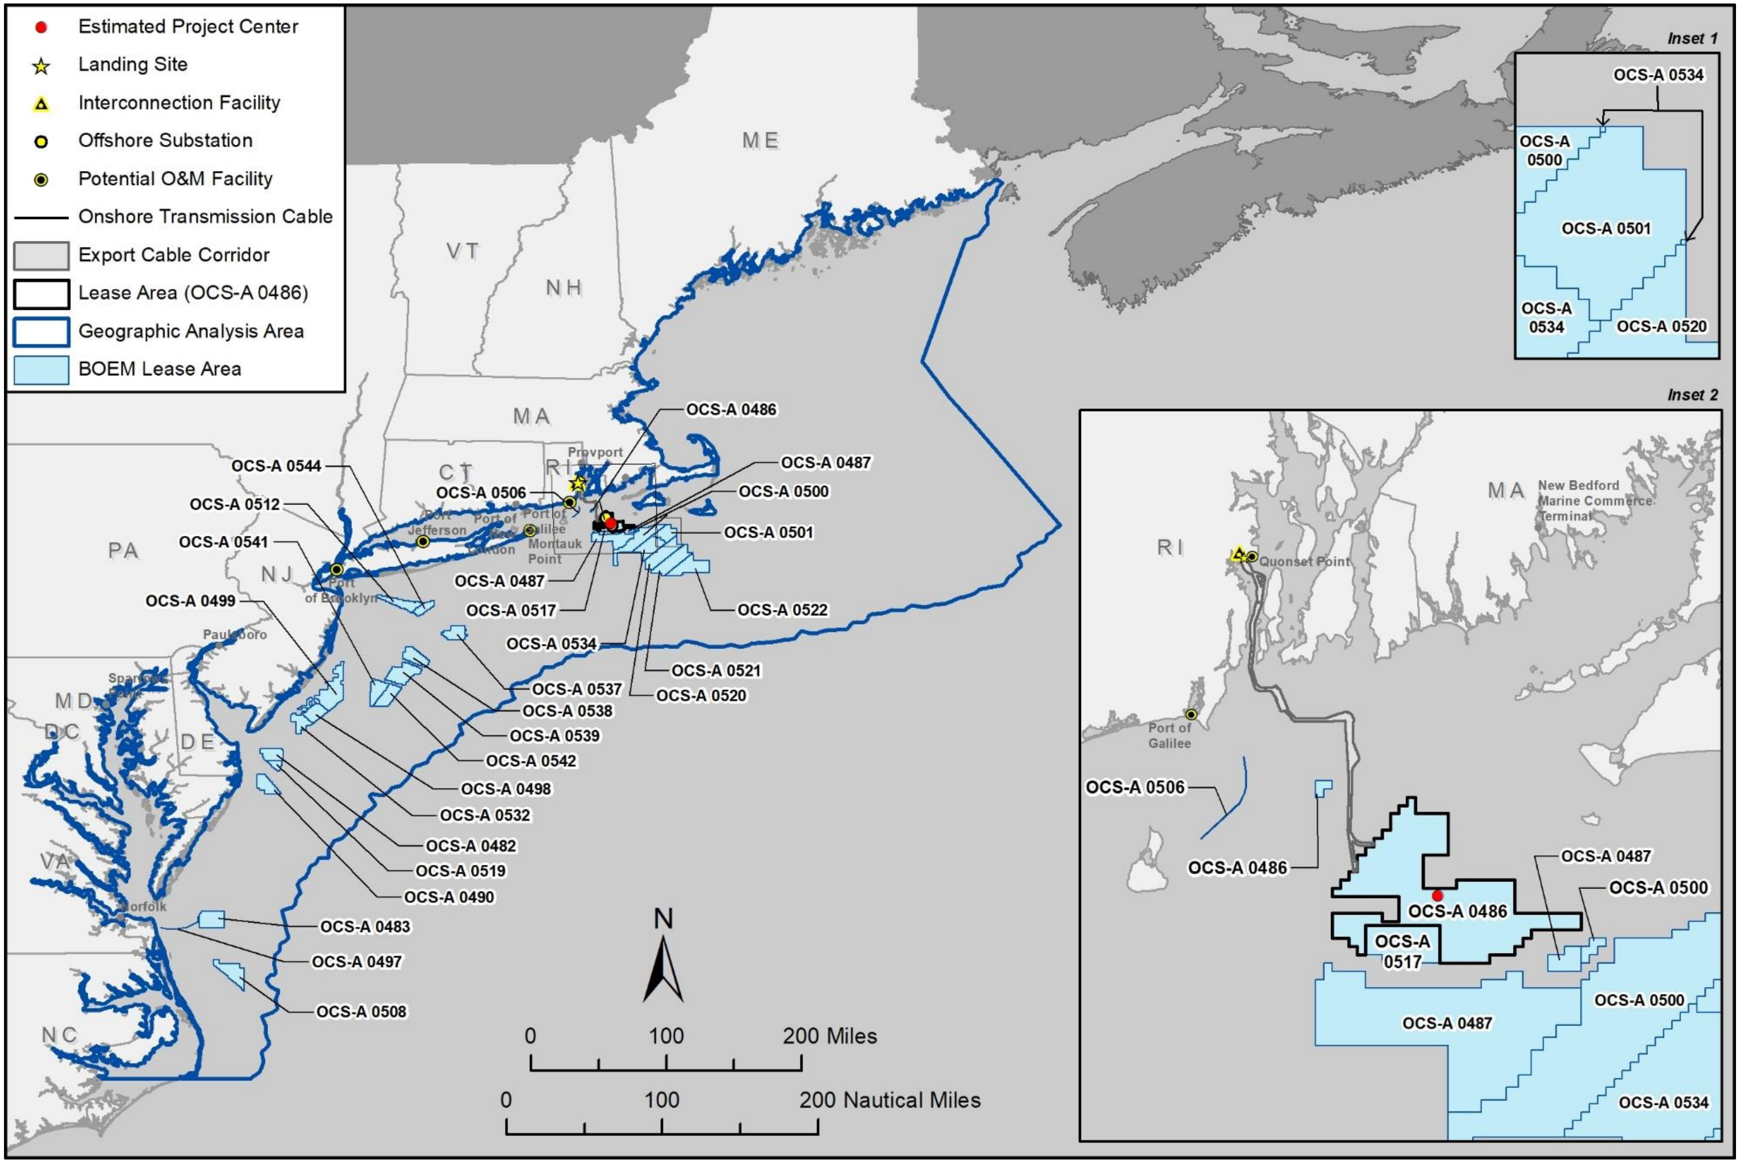

**Figure 3.17-1. Geographic analysis areas for other marine uses: scientific research and surveys.**

Regular fisheries management and ecosystem monitoring surveys conducted by or in coordination with the NEFSC would overlap offshore wind lease areas in the New England region and south into the mid-Atlantic region. Surveys include 1) the NEFSC Bottom Trawl Survey, a more than 50-year multispecies stock assessment tool using a bottom trawl; 2) the NEFSC Sea Scallop/Integrated Habitat Survey, a sea scallop stock assessment and habitat characterization tool using a bottom dredge and camera tow; 3) the NEFSC Surfclam/Ocean Quahog Survey, a stock assessment tool for both species using a bottom dredge; 4) the NEFSC Ecosystem Monitoring Program, a more than 40-year shelf ecosystem monitoring program using plankton tows and conductivity, temperature, and depth units; 5) NOAA's Atlantic Marine Assessment Program for Protected Species aerial and shipboard survey; and 6) North Atlantic Right Whale Sighting Advisory System aerial survey (BOEM 2021). As future wind development continues, alternative platforms, sampling designs, and sampling methodologies would be needed to maintain surveys conducted in or near the Project.

#### 3.17.1.5 Undersea Cables

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to undersea cables from implementation of the Proposed Action and other considered alternatives.

### 3.17.2 Environmental Consequences

#### 3.17.2.1 Relevant Design Parameters, Impact-Producing Factors, and Potential Variances in Impacts

The analysis presented in this section considers the impacts resulting from the maximum design scenario under the PDE approach developed by BOEM to support offshore wind project development (Rowe et al. 2017). The maximum design size specifications defined in Appendix D, Table D-1, are PDE parameters used to conduct this analysis.

The following design parameters would result in different impacts relative to those generated by the design elements considered under the PDE:

- The selection of lower capacity WTG designs would reduce the total WTG height from 873 to as low as 648 feet, reducing impacts to low-flying aircraft.
- The selection of a higher capacity WTG design would reduce the total number of fixed structures that survey vessels could be required to avoid.

See Appendix E1 for a summary of IPFs analyzed for other marine uses across all action alternatives. IPFs that are either not applicable to the resource or determined by BOEM to have a negligible adverse effect are excluded from Chapter 3 and provided in Appendix E1, Tables E2-15 to E2-21. Other marine uses subsections that are determined by BOEM to have a minor or less adverse effect from the action alternatives (aviation and air traffic, military uses, land-based radar, and undersea cables) are provided in Appendix E2.

Table 3.17-1 provides a summary of IPF findings carried forward for analysis in this section. Each alternative analysis discussion consists of the construction and installation phase, the O&M phase, the decommissioning phase, and the cumulative analysis. If these analyses are not substantially different, then they are presented as one discussion. This comparison considers the implementation of all EPMs proposed by Revolution Wind to avoid and minimize adverse impacts on other marine uses. These EPMs are summarized in Appendix F, Table F-1.

A detailed analysis of the Proposed Action follows Table 3.17-1. Detailed analysis of other considered action alternatives is also provided below the table if analysis indicates that the alternative(s) would result in substantially different impacts than the Proposed Action. Offshore and onshore IPFs are addressed separately in the analysis if appropriate for the resource; not all IPFs have both an offshore and onshore component. Where feasible, calculations for specific alternative impacts are provided in Appendix E4 to facilitate reader comparison across alternatives.

The conclusion section within each alternative analysis discussion includes rationale for the effects determinations. The overall effect determination for each alternative is **major** adverse for scientific research and surveys.

**Table 3.17-1. Alternative Comparison Summary for Other Marine Uses**

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) Up to 100 WTGs | Alternative C (Habitat Alternative) 64 or 65 WTGs | Alternative G (Preferred Alternative) | Alternative E (Viewshed Alternative) 64 or 81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|---|---|
| **Scientific Research and Surveys** | | | | | | | |
| Anchoring and new cable emplacement/ maintenance | **Offshore: O**ffshore energy facility construction of new cable emplacement and maintenance of cables would involve increased vessel traffic, which could impact scientific research and surveys by increasing the number of vessels, increasing navigational complexity and risk of collisions. However, these impacts are expected to be limited because cable emplacement vessels would be restricted to emplacement corridors and their activities would be of short duration. Therefore, the effects of anchoring and new cable emplacement and maintenance on scientific research and surveys would be **negligible** adverse. | **Offshore:** Vessel anchoring, cable installation, seafloor preparation, and placement of cable protection activities would occur during Project construction and O&M that could impact scientific research and survey uses. Impacts are expected to be limited because cable emplacement vessels would be restricted to emplacement corridors, and their activities would be of short duration. Therefore, the effects of anchoring and new cable emplacement and maintenance under the Proposed Action on scientific research and studies would be **negligible** adverse.<br>Reasonably foreseeable future actions in combination with the Proposed Action could result in up to 11,631 acres that could be affected by anchoring and mooring and up to 105,390 acres for cable installation activities during offshore wind energy development within the GAA. Therefore, the Proposed Action when combined with past, present, and other reasonably foreseeable project impacts would result in **minor** adverse impacts on scientific research and survey. | **Offshore:** all offshore impacts under Alternatives C through F would result in a noticeably smaller offshore impact compared to the maximum case under the Proposed Action. The effects of this IPF would therefore be the same or slightly reduced relative to those described for the Proposed Action: **negligible** adverse for construction and O&M and **minor** adverse for cumulative. | | | | Offshore: All offshore impacts under Alternatives G would result in a noticeably smaller offshore footprint and reduced IAC cable length compared to the maximum case under the Proposed Action. The estimated construction impact footprint for this IPF is 4,291 acres under Alternative G and 3,803 to 3,812 acres under Alternatives G1 through G3. The effects of this IPF would therefore be similar to the Proposed Action but reduced in extent: **negligible** adverse for construction and O&M and **minor** adverse for cumulative. |
| Light | **Offshore:** Future offshore wind activities without the Proposed Action would result in an increase in permanent aviation warning lighting on WTGs offshore. The increase in light in the area could change conditions or species' behavior, which could impact the results of scientific research and surveys. Therefore, impacts from structural lighting alone on scientific research and surveys under the No Action Alternative would be **minor** adverse. | **Offshore:** Construction and installation and O&M of the Proposed Action would result in an increase in lighting on WTGs offshore, which could have minor adverse effects on scientific research and surveys by impacting the natural environment and changing conditions compared to other areas used for scientific research and surveys that do not have artificial light. The increase in light in the area could change species' behavior, which could impact the results of scientific research and surveys. Therefore, impacts from structural lighting alone on scientific research and surveys under the No Action Alternative would be **minor** adverse. | **Offshore:** While Alternatives C through F could result in a reduction in construction and operational lighting, the effects of this IPF on scientific research and surveys would otherwise be similar to those described for the Proposed Action. Therefore, the impact on scientific research and surveys under this alternative would be **minor** adverse. | | | | Offshore: Although Alternatives G would result in a reduction in construction and operational lighting, the effects of this IPF on scientific research and surveys would otherwise be similar to the Proposed Action. Therefore, the impact on scientific research and surveys under this alternative would be **minor** adverse. |
| Presence of structures | **Offshore:** Offshore wind facilities could adversely affect scientific surveys by preclusion of NOAA survey vessels and aircraft from sampling in survey strata and impacts on the random-stratified | **Offshore:** NMFS scientific research and protected species surveys could be curtailed within the Lease Area due to Project activities, and NMFS believes that construction of the RWF and the | **Offshore:** While the offshore footprint would be reduced under all configurations, the effects of this IPF on scientific research and surveys under Alternatives C through F would otherwise be similar to those described for the Proposed Action. Therefore, the impact of this IPF on scientific research and surveys would be **major** adverse**.** | | | | Offshore: Although the offshore footprint would be reduced under Alternative G (e.g., the maximum construction disturbance footprint is estimated at 583 acres for Alternative G and 482 acres for Alternatives G1 |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) Up to 100 WTGs | Alternative C (Habitat Alternative) 64 or 65 WTGs | Alternative G (Preferred Alternative) | Alternative E (Viewshed Alternative) 64 or 81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|---|---|
| | statistical design that is the basis for assessments, advice, and analyses. Scientific survey and protected species survey operations would therefore be reduced or eliminated as offshore wind facilities are constructed (BOEM 2021).<br>Overall, the No Action Alternative would have **major** adverse effects on NMFS' scientific research and protected species surveys, potentially leading to impacts on fishery participants and communities, as well as potential **major** adverse impacts on monitoring and assessment activities associated with recovery and conservation programs for protected species. | survey adjustments needed would constitute a long-term **major** adverse impact on those surveys. | | | | | through G3), the effects of this IPF on scientific research and surveys would otherwise be similar to the Proposed Action. Therefore, the impact of this IPF on scientific research and surveys would be **major** adverse. |
| Vessel traffic | **Offshore:** Increased vessel traffic due to future offshore wind facilities could lead to course changes of scientific and research vessels, congestion and delays at ports, and increased traffic along vessel transit routes. Therefore, the effects of vessel traffic on scientific and research surveys under the No Action Alternative would be **minor** adverse. | **Offshore:** Increased vessel traffic due to construction and installation and O&M of the Proposed Action could lead to course changes of scientific and research vessels and increased traffic along vessel transit routes. Additionally, offshore construction activities of Project facilities could be a hazard to scientific research vessels as they could experience hazards from passing Project construction vessels. With EPMs, however, the Proposed Action would be **minor** adverse for vessel traffic.<br>Vessel activity could peak with as many as 262 vessels involved in construction of reasonably foreseeable projects. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would be **minor** adverse. | **Offshore:** Vessel traffic associated with Alternatives C through F may result in slightly reduced vessel traffic in the Lease Area and around ports given the smaller offshore footprint. While the offshore footprint would be reduced under all configurations, vessel traffic is expected to remain at similar levels as vessel traffic under the Proposed Project. Reduced navigational complexity combined with a smaller construction footprint and fewer offshore structures would result in the effects of this IPF being the same or slightly reduced relative to those described for the Proposed Action. Therefore, impacts on scientific research and surveys would be **minor** adverse under all Project phases. | | | | Offshore: Vessel traffic associated with Alternatives G may be slightly reduced in the Lease Area and around ports, given the smaller offshore footprint. Although the offshore footprint and IAC cable length would be reduced, vessel traffic is expected to remain at similar levels as vessel traffic under the Proposed Action. Reduced navigational complexity combined with a smaller construction footprint and fewer offshore structures would result in the effects of this IPF being the same or slightly reduced relative to the Proposed Action. Therefore, impacts on scientific research and surveys would be **minor** adverse under all Project phases. |

#### 3.17.2.2 Alternative A: Impacts of the No Action Alternative on Aviation and Air Traffic

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to aviation and air traffic control from implementation of the No Action Alternative.

#### 3.17.2.3 Alternative A: Impacts of the No Action Alternative on Land-Based Radar

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to aviation and air traffic control from implementation of the No Action Alternative.

#### 3.17.2.4 Alternative A: Impacts of the No Action Alternative on Military and National Security (including Search and Rescue)

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to aviation and air traffic control from implementation of the No Action Alternative.

#### 3.17.2.5 Alternative A: Impacts of the No Action Alternative on Scientific Research and Surveys

##### 3.17.2.5.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for scientific research and surveys (see Section 3.17.1) would continue to follow current regional trends and respond to IPFs introduced by other ongoing activities and by permitted and constructed offshore wind COP projects within the GAA. These IPFs are described and analyzed in Appendix E1.

##### 3.17.2.5.2 Cumulative Impacts

This section discloses potential scientific research and surveys impacts associated with future offshore wind development (without the Proposed Action). The cumulative impact analysis for the No Action Alternative for planned non-offshore wind activities, as well as activities associated with constructed or approved offshore wind projects (without the Proposed Action), is provided in Appendix E1.

<u>Anchoring and new cable emplacement/maintenance:</u> Up to 8,427 acres could be affected by anchoring/mooring activities and up to acres of 101,381 acres of cable installation during offshore wind energy development within the GAA. This offshore energy facility construction of new cable emplacement and maintenance of cables would involve increased vessel traffic, which could impact scientific research and surveys by increasing the number of vessels within the GAA. Increased vessel traffic due to anchoring and cable maintenance of wind facilities could lead to course changes of scientific research vessels, thereby increasing navigational complexity and risk of collisions. These impacts are expected to be the highest during construction phases and lower during infrequent yearly routine maintenance and monitoring of offshore wind activities. Therefore, the effects of anchoring and new cable emplacement and maintenance under the No Action Alternative on scientific research and surveys would be **negligible** adverse.

<u>Light:</u> Future offshore wind activities without the Proposed Action would result in an increase in permanent aviation warning lighting on WTGs offshore. All existing stationary structures would have

navigation marking and lighting in accordance with FAA, USCG, and BOEM guidance to minimize allision risks. Implementation of navigational lighting and marking per FAA and BOEM requirements and guidelines would further reduce the risk of scientific research vessel collisions. This would result in a general increase of lights in the GAA, which could impact the natural environment and alter research conditions compared to other areas used for scientific research and surveys that do not have artificial light. The increase in light in the area could change species' behavior, which could impact the results of scientific research and surveys. Therefore, impacts from structural lighting alone on scientific research and surveys under the No Action Alternative would be **minor** adverse.

Presence of structures: This EIS incorporates, by reference, the detailed analysis of potential impacts to scientific research and surveys provided in the Vineyard Wind final EIS (BOEM 2021). Activities associated with offshore wind development such as site assessment activities, construction of reasonably foreseeable offshore wind farms (including placement of structures such as OSSs and WTGs), associated cable systems, and vessel activity would present additional navigational obstructions for sea and air-based scientific surveys. If construction of all projected future offshore wind facilities occurs along the Atlantic coast, these developments would add up to as many as 3,088 structures between by 2030. Collectively, these developments would prevent NMFS from continuing ongoing scientific research surveys or protected species surveys under current vessel capacities and could reduce future opportunities for NMFS' scientific research in the area.

NMFS scientific surveys that overlap with wind development areas collectively represent over 277 survey-years of total effort by dedicated NOAA ship and aircraft resources. Data gathered from these surveys represent some of the most comprehensive data on marine ecosystems in the world, and data within offshore wind development areas are essential to those datasets in the Northwest Atlantic Ocean. These data support fisheries assessments and management actions, protected species assessments and management actions, ecosystem-based fisheries management, and regional and national climate assessments, as well as a number of regional, national, and international science activities.

Within offshore wind facility areas, survey operations would be curtailed or eliminated under current vessel capacities and monitoring protocols. Specifically, coordinators of large vessel survey operations or operations deploying mobile survey gear have currently determined activities within offshore wind facilities are not within their safety and operational limits. The need for survey vessels to navigate around large offshore wind projects to access survey stations would cause a loss of efficiency for surveys conducted outside the wind energy areas by reducing sampling time available with limited sea day allocations for survey vessels. In addition, changes in required flight altitudes due to proposed turbine height would affect aerial survey design and protocols. Stock assessment surveys for fisheries and protected species and ecological monitoring surveys considered in this analysis include, but are not limited to the NMFS spring and fall multi-species bottom trawl surveys; the NMFS surf clam survey; the NMFS ocean quahog survey; the NMFS integrated benthic survey/Atlantic scallop survey (optical and dredge); NMFS winter, spring, summer and fall ecosystem monitoring surveys; the NMFS North Atlantic right whale photographic sightings surveys (aerial); the NMFS marine mammal, sea turtle, and seabird vessel surveys; the NMFS marine mammal and sea turtle aerial surveys; the Virginia Institute of Marine Science scallop dredge survey; and the Northeast Area Monitoring and Assessment Program surveys.

In summary, offshore wind facilities could adversely affect scientific surveys by preclusion of NOAA survey vessels and aircraft from sampling in survey strata and impacts on the random-stratified statistical design that is the basis for assessments, advice, and analyses. Scientific survey and protected species survey operations would therefore be reduced or eliminated as offshore wind facilities are constructed (BOEM 2021). Offshore wind facilities would disrupt survey sampling statistical designs, such as random stratified sampling. Impacts to the statistical design of region-wide surveys violate the assumptions of probabilistic sampling methods. Development of new survey technologies, changes in survey methodologies, and required calibrations could help to mitigate losses in accuracy and precision of current practices due to the impacts of wind development on survey strata.

Other offshore wind projects could also require implementation of mitigation and monitoring measures through BOEM approvals or consultations. Identification and analysis of specific measures are speculative at this time; however, these measures could further impact NMFS's ongoing scientific research surveys or protected species surveys because of the increased vessel activity and/or in-water structures from these other projects.

BOEM and NOAA have developed a federal survey mitigation strategy for Vineyard Wind that is currently undergoing public review and that addresses potential impacts of offshore wind energy development on NOAA Fisheries' scientific surveys (Hare et al. 2022).

Overall, the No Action Alternative would have **major** adverse effects on NMFS' scientific research and protected species surveys, potentially leading to impacts on fishery participants and communities, as well as potential **major** adverse impacts on monitoring and assessment activities associated with recovery and conservation programs for protected species. Therefore, the effects of the presence of structures on scientific research and surveys under the No Action Alternative would be **major** adverse.

<u>Vessel traffic:</u> Although no future non–offshore wind stationary structures were identified within the Lease Area, increased vessel traffic due to future offshore wind facilities located outside of the Lease Area could lead to course changes of scientific and research vessels, congestion and delays at ports, and increased traffic along vessel transit routes. Vessel activity could peak in 2025 with as many as 210 vessels involved in construction of reasonably foreseeable OSW projects. While construction periods of various wind energy facilities may be staggered, some overlap would result in a cumulative impact to traffic loads. Therefore, the effects of vessel traffic on scientific and research surveys under the No Action Alternative would be **minor** adverse.

#### 3.17.2.5.3 Conclusions

Under the No Action Alternative, BOEM would not approve the COP; Project construction and installation, O&M, and decommissioning would not occur; and potential impacts on other marine uses associated with the Project would not occur. However, ongoing and future activities would have **major** adverse impacts on scientific research and surveys due to the presence of structures that reduce future opportunities for NMFS' scientific research in the area.

BOEM anticipates **moderate** adverse impacts on scientific research and surveys due to the impacts of ongoing offshore wind activities (BIWF). BOEM anticipates that the impacts to reasonably foreseeable offshore wind activities would be **major** adverse, primarily because of the potential impacts of structures to NMFS survey efforts. The No Action Alternative would forgo the fisheries and benthic habitat monitoring that Revolution Wind has committed to voluntarily perform. Therefore, the results of this monitoring would not be available to provide an understanding of the effects of offshore wind development; benefit future management of finfish, invertebrates, and EFH; or inform planning of other offshore developments. However, other ongoing and future surveys could still provide similar data to support similar goals.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the GAA combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore would result in **major** adverse impacts for scientific research and surveys and USCG SAR activities (of people or marine mammals). The presence of stationary structures could prevent or hamper continued NMFS scientific research surveys using current vessel capacities and monitoring protocols or reduce opportunities for other NMFS scientific research surveys in the area. Coordinators of large vessel survey operations or operations deploying mobile survey gear have determined that activities within offshore wind facilities would not be within current safety and operational limits. In addition, changes in required flight altitudes due to the proposed WTG height would affect aerial survey design and protocols. BOEM acknowledges that NOAA's Office of Marine and Aviation Operations endorses the restriction of large vessel operations to greater than 1 nm from wind installations due to safety and operational challenges.

#### 3.17.2.6 Alternative A: Impacts of the No Action Alternative on Undersea Cables

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to aviation and air traffic control from implementation of the No Action Alternative.

#### 3.17.2.7 Alternative B: Impacts of the Proposed Action on Aviation and Air Traffic

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to aviation and air traffic control from implementation of the Proposed Action and other considered alternatives.

#### 3.17.2.8 Alternative B: Impacts of the Proposed Action on Land-Based Radar

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to land-based radar from implementation of the Proposed Action and other considered alternatives.

#### 3.17.2.9 Alternative B: Impacts of the Proposed Action on Military and National Security (including Search and Rescue)

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to military and national security from implementation of the Proposed Action and other considered alternatives.

### 3.17.2.10 Alternative B: Impacts of the Proposed Action on Scientific Research and Surveys

#### 3.17.2.10.1 Construction and Installation

**Offshore Activities and Facilities**

Anchoring and new cable emplacement/maintenance: Vessel anchoring, cable installation, seafloor preparation, and placement of cable protection activities would occur during Project construction. This would involve increased construction vessel traffic that could impact scientific research and survey uses by increasing the number of vessels within the GAA. Additionally, cable emplacement could impact bottom-trawl NMFS surveys that are planned in wind areas, although it is likelier that the development of the RWF would preclude scientific research and studies from occurring in the GAA, which would result in a greater impact discussed under Presence of Structures. Impacts specific to anchoring and cable emplacement during Project construction would be restricted to cable emplacement corridors, which would result in limited contact with cable emplacement installation vessels. Therefore, the effects of anchoring and new cable emplacement and maintenance under the Proposed Action on scientific research and studies would be **negligible** adverse.

Light: Construction and installation of the Proposed Action would result in an increase in temporary construction lighting on WTGs offshore. All existing stationary structures would have navigation marking and lighting in accordance with FAA, USCG, and BOEM guidance to minimize collision risks. This would result in a general increase of lights in the GAA, which could have minor adverse effects on scientific research and surveys by impacting the natural environment and changing conditions compared to other areas used for scientific research and surveys that do not have artificial light. The increase in light in the area could change species' behavior, which could impact the results of scientific research and surveys. Therefore, impacts from structural lighting alone on scientific research and surveys under the No Action would be **minor** adverse.

Presence of structures and vessel traffic: Scientific research and protected species surveys could be affected from the construction of the RWF and RWEC. Some vessels or low-flying aircraft could be required to alter course to avoid WTGs. During review of other wind energy proposals, BOEM found that that NOAA Fisheries experienced reduced sampling productivity because of impacts associated with the presence of wind energy structures (Hare et al. 2022). NOAA has concluded that, within offshore wind facility areas, survey operations would be curtailed, if not eliminated, under current vessel capacities and monitoring protocols. Specifically, coordinators of large vessel survey operations or operations deploying mobile survey gear have currently determined that activities within offshore wind facilities are not within their safety and operational limits. Vessels could be required to make minor course adjustments to avoid collisions but would not be completely blocked from using the areas around the WTGs. Nevertheless, NMFS scientific research and protected species surveys could be curtailed within the Lease Area, and NMFS believes that construction of the RWF and the survey adjustments needed would constitute a long-term **major** adverse impact on those surveys.

Increased vessel traffic due to construction and installation of the Proposed Action could lead to course changes of scientific and research vessels and increased traffic along vessel transit routes. Additionally, offshore construction activities of Project facilities could be a hazard to scientific research vessels as they could experience hazards from passing Project construction vessels. Two primary means of reducing this risk are updates to mariners from the Project and safety zones around construction activity. Revolution Wind has committed to informing fishermen and other mariners about offshore activities related to the RWF. Fisheries liaisons and a team of fisheries representatives are based in regional ports, and updates would be provided to mariners online and via twice-daily updates on very high frequency channels. Safety zones can also protect mariners from potential hazards during construction activities. It is anticipated that the Coast Guard would implement safety zones during construction of the Project, as they did for the construction of the BIWF (USCG 2016). To reduce the likelihood of allision or collision during construction, Project safety vessel(s) would be on scene to advise mariners of construction activity (DNV GL Energy USA, Inc. 2020).

Because NMFS surveys could be curtailed in the Lease Area and because of increased collision risk, the effects of presence of structures and vessel traffic on scientific and research surveys under the Proposed Action would be **major** adverse for presence of structures and **minor** adverse for vessel traffic**.**

#### 3.17.2.10.2 Operations and Maintenance and Decommissioning

#### Offshore Activities and Facilities

Anchoring and new cable emplacement/maintenance: Vessel anchoring and cable maintenance would occur during Project O&M and decommissioning. This would involve a slight increase in construction vessel traffic that could impact scientific research and survey uses by increasing the number of vessels within the GAA. Impacts specific to anchoring and cable emplacement during Project O&M and decommissioning are expected to be restricted to cable emplacement corridors, which would result in limited contact with cable emplacement and maintenance vessels. Cables associated with the RWF would be removed as part of decommissioning. Therefore, the effects of anchoring and new cable emplacement and maintenance under the Proposed Action on scientific research and studies would be **negligible** adverse.

Light: O&M and decommissioning of the Proposed Action would result in an increase in permanent lighting on up to 100 WTGs offshore. All existing stationary structures would have navigation marking and lighting in accordance with FAA, USCG, and BOEM guidance to minimize collision risks. Implementation of navigational lighting and marking per USCG and BOEM requirements and guidelines would further reduce the risk of scientific vessel collisions. This would result in a general increase of lights in the GAA, which could have a negative impact on scientific research and surveys by impacting the natural environment and changing conditions compared to other areas used for scientific research and surveys that do not have artificial light. The increase in light in the area could change species' behavior, which could impact the results of scientific research and surveys. Light impacts are expected to be **minor** adverse compared with other impacts discussed below in Presence of structures and vessel traffic. Lighting would be removed as part of WTG and OSS decommissioning. Therefore, impacts from structural lighting alone on scientific research and surveys under the Proposed Action would be **minor** adverse.

Presence of structures and vessel traffic: Scientific research and protected species surveys could be affected from the O&M and decommissioning of the RWF and RWEC. Some vessels or low-flying aircraft could be required to alter course to avoid WTGs. During review of other wind energy proposals, BOEM found that that NOAA Fisheries experienced reduced sampling productivity because of impacts associated with the presence of wind energy structures (Hare et al. 2022). NOAA has concluded that, within offshore wind facility areas, survey operations would be curtailed, if not eliminated, under current vessel capacities and monitoring protocols. Specifically, coordinators of large vessel survey operations or operations deploying mobile survey gear have currently determined that activities within offshore wind facilities are not within their safety and operational limits. Vessels could be required to make minor course adjustments to avoid collisions but would not be completely blocked from using the areas around the WTGs. Nevertheless, NMFS scientific research and protected species surveys could be curtailed within the Lease Area, and NMFS believes that construction of the RWF and the survey adjustments needed would constitute a long-term **major** adverse impact on those surveys.

Increased vessel traffic due to O&M and decommissioning of the Proposed Action could lead to course changes of scientific and research vessels and increased traffic along vessel transit routes. However, less vessel traffic is anticipated during O&M and decommissioning than during construction and installation activities. Additionally, during operations, each WTG foundation would serve as an aid to navigation (ATON) for mariners as they are large structures that would be lighted and marked as required by applicable law and regulation, and as included in any/all conditions the Coast Guard may impose in conjunction with its private aids to navigation (PATON) permits. The Project structures and seaward components would be clearly marked on applicable NOAA nautical charts, including Chart No. 13218 (NOAA 2020). Revolution Wind would work closely with the USCG and NOAA to chart all elements of the Project (DNV GL Energy USA, Inc. 2020; Orsted 2020).

Therefore, the effects of presence of structures and vessel traffic on scientific and research surveys under the Proposed Action for O&M and decommissioning would be **major** adverse for presence of structures and **minor** adverse for vessel traffic.

#### 3.17.2.10.3 Cumulative Impacts

##### Offshore Activities and Facilities

<u>Anchoring and new cable emplacement/maintenance:</u> Up to 11,631 acres could be affected by anchoring/mooring activities and up to 105,390 acres could be affected by cable installation during construction and installation of offshore elements of the RWF, combined with other reasonably foreseeable future actions. Construction of offshore elements of the RWF would involve cable emplacement, which would involve increased vessel traffic. This could create conflicts with scientific and research vessels by increasing the number of vessels within the GAA and the number of cables constructed. However, the cable emplacement vessels would be restricted to cable emplacement corridors, which would result in limited contact with scientific and research vessels. Therefore, the Proposed Action when combined with past, present, and other reasonably foreseeable project impacts would result in **minor** adverse impacts on scientific research and surveys.

<u>Light:</u> The Proposed Action would result in an increase in temporary lighting and permanent aviation warning lighting on WTGs offshore. All existing stationary structures would have navigation marking and lighting in accordance with FAA, USCG, and BOEM guidance to minimize collision risks. Implementation of navigational lighting and marking per USCG and BOEM requirements and guidelines would further reduce the risk of scientific vessel collisions. This would result in a general increase of lights in the GAA, which could have an impact on scientific and research surveys by increasing navigational complexity. Reasonably foreseeable activities combined with the Proposed Action would also increase lighting in the area and would include up to 3,190 additional lighted structures in the GAA.

Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would be **minor** adverse.

<u>Presence of structures:</u> This EIS incorporates by reference the detailed analysis of potential impacts to scientific research and surveys provided in the Vineyard Wind final EIS (BOEM 2021). In response to the impacts to scientific surveys identified in the Vineyard Wind final EIS, BOEM and NOAA developed a federal survey mitigation strategy for offshore wind energy development in the northeast region (see Section 3.17.2.22 and Table F-2, Appendix F).

Without this mitigation, the Proposed Action would result in long-term **major** adverse impacts to scientific research and surveys through the installation of up to 100 WTGs and two OSSs. The Proposed Action structures represent a 3% increase over the total estimated 3,088 WTG and OSS foundations under the No Action Alternative that could be present along the Atlantic coast if all projected future offshore wind facilities are constructed. Within the GAA, BOEM estimates a cumulative total of 3,190 offshore WTG and OSS foundations for the Proposed Action plus all other future offshore wind projects. These structures would result in adverse impacts to NMFS' scientific research and protected species surveys due to 1) WTG blade tip height that would exceed the survey altitude for current surveying methodologies, and 2) Lease Area geographic overlap with ongoing NMFS' Northeast Fisheries Science Center fishery resource monitoring surveys. Research and monitoring proposed by the lessees and/or conducted by other scientific institutions would continue in offshore wind facilities. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would consist predominately of impacts described under the No Action Alternative, which would represent a long-term **major** adverse impact on NMFS's scientific research and protected species surveys and the resulting stock assessments.

<u>Vessel traffic:</u> The Proposed Action would result in increased vessel traffic due to construction and installation, O&M, and decommissioning of the Proposed Action that could lead to course changes of scientific and research vessels and increased traffic along vessel transit routes. Additionally, increased vessel traffic due to reasonably foreseeable future actions could lead to course changes of scientific and research vessels, congestion and delays at ports, and increased traffic along vessel transit routes. Vessel activity could peak with as many as 262 vessels involved in construction of reasonably foreseeable projects. While construction periods of various wind energy facilities could be staggered, some overlap would result in a cumulative impact to traffic loads. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would be **minor** adverse.

### 3.17.2.10.4 Conclusions

Project construction and installation, O&M, and decommissioning would affect ongoing scientific research studies occurring in the GAA. Similar impacts from Project O&M would occur, although at a lesser extent and duration for some uses. BOEM anticipates that the impacts resulting from the Proposed Action alone would range from **negligible** to **major** adverse. Therefore, BOEM expects that the overall impact on scientific research and surveys from the Proposed Action alone to be **major** adverse.

In the context of other reasonably foreseeable environmental trends and planned actions, the impacts under the Proposed Action resulting from individual IPFs would range from **negligible** to **major** adverse. Considering all the IPFs together, BOEM anticipates that the overall impacts associated with the

Proposed Action when combined with past, present, and reasonably foreseeable activities would be **major** adverse for scientific research and surveys.

#### 3.17.2.11 Alternative B: Impacts of the Proposed Action on Undersea Cables

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to undersea cables from implementation of the Proposed Action and other considered alternatives.

#### 3.17.2.12 Alternatives C, D, E, and F: Aviation and Air Traffic

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to aviation and air traffic control from implementation of the Proposed Action and other considered alternatives.

#### 3.17.2.13 Alternatives C, D, E, and F: Land-Based Radar

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to land-based radar from implementation of the Proposed Action and other considered alternatives.

#### 3.17.2.14 Alternatives C, D, E, and F: Military and National Security (including Search and Rescue)

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to military and national security from implementation of the Proposed Action and other considered alternatives.

#### 3.17.2.15 Alternatives C, D, E, and F: Scientific Research and Surveys

Table 3.17-1 provides a summary of IPF findings by alternative.

##### 3.17.2.15.1 Conclusions

Although Alternatives C through F would reduce the number of WTGs and their associated inter-array cables, which would have an associated reduction in associated vessel traffic, BOEM expects that the impacts resulting from each alternative alone would be the same as the Proposed Action: **major** adverse. The overall impacts of Alternatives C through F when combined with past, present, and reasonably foreseeable activities would therefore be the same as under the Proposed Action: **major** adverse for scientific research and protected species surveys.

#### 3.17.2.16 Alternatives C, D, E, and F: Undersea Cables

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to undersea cables from implementation of the Proposed Action and other considered alternatives.

#### 3.17.2.17 Alternative G: Impacts of the Preferred Alternative on Aviation and Air Traffic

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to aviation and air traffic control from implementation of the Proposed Action and other considered alternatives.

#### 3.17.2.18 Alternative G: Impacts of the Preferred Alternative on Land-Based Radar

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to land-based radar from implementation of the Proposed Action and other considered alternatives.

#### 3.17.2.19 Alternative G: Impacts of the Preferred Alternative on Military and National Security (including Search and Rescue)

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to military and national security from implementation of the Proposed Action and other considered alternatives.

#### 3.17.2.20 Alternative G: Impacts of the Preferred Alternative on Scientific Research and Surveys

Table 3.17-1 provides a summary of IPF findings for this alternative.

##### 3.17.2.20.1 Conclusions

The construction and installation, O&M, and decommissioning of Alternative G would affect ongoing scientific research studies occurring in the GAA through the same mechanisms described for the Proposed Action, including increased vessel activity, presence of structures, light, and anchoring and cable emplacement. Although the overall extent of impacts to scientific research and surveys would be reduced under Alternative G relative to the Proposed Action, the significance of those effects would be the same. Therefore, the impacts of Alternative G alone on scientific research and surveys would be **major** adverse. Considering all IPFs together, BOEM anticipates that the overall impacts associated with Alternative G when combined with past, present, and reasonably foreseeable activities would be **major** adverse for scientific research and surveys.

#### 3.17.2.21 Alternative G: Impacts of the Preferred Alternative on Undersea Cables

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to undersea cables from implementation of the Proposed Action and other considered alternatives.

#### 3.17.2.22 Mitigation

Mitigation measures resulting from agency consultations for other marine uses (scientific research and surveys) are identified in Appendix F, Table F-2, and addressed in Table 3.17-2. Additional mitigation measures identified by BOEM and cooperating agencies are described in detail in Appendix F, Table F-3, and addressed in Table 3.17-3. If one or more of the measures analyzed below are adopted by BOEM and/or cooperating agencies, some adverse impacts could be further reduced.

**Table 3.17-2. Mitigation and Monitoring Measures Resulting from Consultations for Other Marine Uses (scientific research and surveys) (Appendix F, Table F-2)**

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| WTG shutdown mechanism | Equip all WTG rotors (blade assemblies) with control mechanisms operable from the RWF control centers available 24 hours a day, 7 days a week. The control mechanisms shall enable control room operators to shut down the requested WTGs within an agreed-upon time of notification between the USCG and Revolution Wind. A formal shutdown procedure would be part of the standard operating procedures and periodically tested. Normally, USCG-ordered shutdowns would be limited to those WTGs in the immediate vicinity of an emergency and for as short a period as is safely practicable under the circumstances, as determined by the USCG. | This measure would not alter the impact determination for military and national security activities but would ensure that effects of project operations to SAR, pollution events, and other emergency response activities would be limited to levels considered herein. |
| USCG training and exercises | Revolution Wind would participate in periodic USCG-coordinated training and exercises to test and refine notification and shutdown procedures and to provide SAR training opportunities for USCG vessels and aircraft. | This measure would not alter the impact determination for military and national security activities but would ensure that effects of project operations to SAR, pollution events, and other emergency response activities would be limited to levels considered herein. |
| Operations and maintenance plan | Before the project becomes operational, Revolution Wind shall submit a written plan for O&M, which includes control center(s), for review by BOEM and the USCG. The plan must demonstrate that the control center(s) would be adequately staffed to perform standard operating procedures, communications capabilities, and monitoring capabilities necessary to support USCG activities. The plan shall include, but not be limited to, the following topics, which may be modified through ongoing discussions with the USCG:<br>Standard operating procedures: Methods for establishing and testing WTG rotor shutdown; methods of lighting control; method(s) for notifying the USCG of mariners in distress or potential/actual SAR incidents; method(s) for notifying the USCG of any events or incidents that may impact maritime safety or | This measure would not alter the impact determination for military and national security activities but would ensure that effects of project operations to SAR, pollution events, and other emergency response activities would be limited to levels considered herein. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | security; and methods for providing the USCG with environmental data, imagery, communications, and other information pertinent to SAR or marine pollution response.<br>Staffing: Number of personnel intended to staff the control center(s) to ensure continuous monitoring of WTG operations, communications, and surveillance systems.<br>Communications: Capabilities to be maintained by the control center(s) to communicate with the USCG and mariners within and near the Lease Area. Communications capability shall at a minimum include very high frequency (VHF) marine radio and landline and wireless for voice and data.<br>Monitoring: The control center(s) should maintain the capability to monitor RWF installation and operations in real time (including night and periods of poor visibility) for determining the status of all PATONs and detection of a survivor who has climbed to the survivor's platform, if installed, on any WTG or OSS. | |
| Helicopter landing platforms | If Revolution Wind's OSSs include helicopter landing platforms, those platforms would be designed and built to accommodate up to and including USCG H-60-sized rescue helicopters. | This measure would not alter the impact determination for military and national security activities but would ensure that effects of project operations to SAR, pollution events, and other emergency response activities would be limited to levels considered herein. |
| Fiber-optic sensing technology | Distributed fiber-optic sensing technology proposed for the Project or associated transmission cables would be reviewed by the DOD to ensure that distributed fiber-optic sensing is not used to detect sensitive data from DOD activities, to conduct any other type of surveillance of U.S. Government operations, or to otherwise pose a threat to national security. | This measure would not alter the impact determination for military and national security but would ensure that these impacts remain negligible. |
| NOAA Fisheries scientific surveys | The project should be required to mitigate the major impacts to NOAA Fisheries scientific surveys consistent with NMFS-BOEM Federal Survey Mitigation Strategy - Northeast U.S. Region. Revolution Wind's plans to mitigate these impacts at the project and regional levels should be provided to NMFS for review and | This measure would not alter the impact determination for scientific research and surveys but would provide a planning and coordination process to ensure the effectiveness of measures used to avoid and minimize adverse impacts on scientific survey activities. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | approval prior to BOEM's decision on its acceptance. Mitigation is necessary to ensure that NOAA Fisheries can continue to accurately, precisely, and timely execute our responsibilities to monitor the status and health of trust resources. | |
| Locations of boulders, berms, and protection measures | Locations of relocated boulders, created berms, and scour protection, including cable protection measures (i.e., concrete mattresses) should be provided to NMFS and the public as soon as possible to help inform marine users, including, but not limited to the fishing industry and entities conducting scientific surveys of potential gear obstructions. | This measure would not alter the impact determination for scientific research and surveys but would help to avoid and minimize adverse impacts on experimental design and sampling gear used to conduct these activities. |

**Table 3.17-3. Additional Mitigation and Monitoring Measures Under Consideration for Other Marine Uses (scientific research and surveys) (Appendix F, Table F-3)**

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| Federal survey mitigation | There are 14 NMFS scientific surveys that overlap with wind energy development in the northeast region and eight of these surveys overlap with the Project. As per NMFS and BOEM Survey Mitigation strategy actions 1.3.1, 1.3.2, 2.1.1, and 2.1.2 (Hare et al. 2022), within 120 calendar days of COP Approval, the Lessee must submit to BOEM a draft survey mitigation agreement between NMFS and the Lessee. The survey mitigation agreement will describe how the Lessee will mitigate the Project impacts on the eight NMFS surveys. If after consultation with NMFS NEFSC, BOEM deems the survey mitigation agreement acceptable, the mitigation will be considered required as a term and condition of the Project's COP approval.<br><br>As soon as reasonably practicable, but no later than 30 days after the issuance of the Project's COP Approval, the Lessee will initiate coordination with NMFS NEFSC to develop the survey mitigation agreement described above. Mitigation activities specified under the agreement will be designed to mitigate the Project impacts on the following NMFS NEFSC surveys: (a) Spring Bottom Trawl survey; (b) Autumn Multi-species Bottom Trawl survey; (c) Ecosystem Monitoring survey; (d) NARW aerial survey; (e) Aerial marine mammal and sea turtle survey; (f) Shipboard marine mammal and sea turtle survey; (g) Atlantic surfclam and ocean quahog survey; and (h) Atlantic sea scallop survey. At a minimum, the survey mitigation agreement will describe actions needed and the means to address impacts on the affected surveys due to the preclusion of sampling platforms and impacts on statistical designs. In terms of statistical design, the project will be viewed as a discrete stratum in surveys that use a random stratified design. Other anticipated Project impacts on NMFS surveys such as changes in habitat and increased operational costs due to loss of sampling efficiencies may also be addressed in the agreement.<br><br>The survey mitigation agreement will identify activities that will result in the generation of data equivalent to data generated by NMFS's affected | This measure would complement existing EPMs. The federal survey mitigation strategy is a long-term plan to help ensure the quality of NOAA's fisheries surveys and data is maintained. Eventually, major long-term impacts to scientific research and surveys could be reduced to minor if monitoring becomes direct mitigation. |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | surveys for the duration of the Project. The survey mitigation agreement will describe the implementation procedures by which the Lessee will work with NEFSC to generate, share, and manage the data required by NEFSC for each of the surveys impacted by the Project, as mutually agreed upon between the Lessee and NMFS/NEFSC. The survey mitigation agreement must also describe the Lessee's participation in the NMFS NEFSC Northeast Survey Mitigation Program to support activities that address regional-level impacts for the surveys listed above. | |

#### 3.17.2.22.1 Measures Incorporated into the Preferred Alternative

Mitigation measures required through completed consultations, authorizations, and permits listed in Table 3.17-4 and in Appendix F, Table F-2, are incorporated into Alternative G (Preferred Alternative). These measures, if adopted, would further define how the effectiveness and enforcement of EPMs would be ensured and would improve accountability for compliance with EPMs by requiring the submittal of plans for approval by the enforcing agency(ies) and by defining reporting requirements. Because these measures would ensure the effectiveness of and compliance with EPMs that are already analyzed as part of the Proposed Action, implementation of these measures would not further reduce the impact level of the Proposed Action from what is described in Section 3.17.2.

## 3.18 Recreation and Tourism

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to recreation and tourism from implementation of the Proposed Action and other considered alternatives.

## 3.19 Sea Turtles

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to sea turtles from implementation of the Proposed Action and other considered alternatives.

# 3.20 Visual Resources

## 3.20.1 Description of the Affected Environment and Environmental Consequences of the No Action Alternative for Visual Resources

Geographic analysis area: The GAA for non-historic visual resources encompasses a 40-mile radius extending from the boundary of the Lease Area and a 3-mile radius encompassing the OnSS and visually sensitive resources within New York, Connecticut, Rhode Island, and Massachusetts (Figure 3.20-1). The GAA comprises approximately 6,113 square miles of open ocean and 1,488 square miles of land and shoreline. Approximately 28 towns or communities in Rhode Island, 33 in Massachusetts, six in Connecticut, and two in New York are within the GAA (EDR 2023). This section addresses information and impacts related to non-historic visual resources. Information and impacts related to historic visual resources can be found in Section 3.10.

Visual resource impacts associated with the Project were evaluated and determined based primarily on information and findings associated with the RWF visual impact assessment (VIA) (EDR 2023) and the application of recently implemented BOEM impact assessment methodology, *Methodology for Assessment of Seascape, Landscape, and Visual Impacts of Offshore Wind Energy Developments on the Outer Continental Shelf of the United States* (seascape, landscape, and visual impact assessment [SLVIA]) (Sullivan 2021). At the request of BOEM, Revolution Wind applied the SLVIA methodology to assess impacts to the viewer's visual experience and impacts to ocean, seascape, and landscape character (Sullivan 2021:29–33). To the extent possible, Revolution Wind used previously documented information associated with the VIA, which pre-dates the SLVIA.

The SLVIA methodology was compared with the VIA to extract previously documented existing view information and landscape similarity zone characteristics (EDR 2023) and was translated into ocean character areas (OCAs), seascape character areas (SCAs), and landscape character areas (LCAs) at a generalized scale following the SLVIA as well as visual conditions and information. A total of 37 viewing condition scenarios (e.g., daytime, sunset, and nighttime) associated with 28 individual key observation points (KOPs) were assessed in the VIA and include photo simulations (EDR 2023:91–145). Additionally, OCA, SCA, and LCA visibility computations, based on SLVIA guidance and VIA information, were compiled and are presented in Tables G-VIS1a through G-VIS10c in Appendix G. For each action alternative, data were compiled and organized based on the best-known information provided in the VIA and compared to the Proposed Action. Additionally, the visibility analysis for each action alternative was analyzed associated with OCAs, SCAs, LCAs, and specially designated areas (SDAs) as was the proximity of KOPs in relation to action alternative variations (e.g., closest WTG and closest removed WTG based on the alternative) to provide geographic context of the overall distance in relation to the KOP. Analysis distances associated with KOPs may deviate between various resources (e.g., cultural and historic resources) based on location-specific analysis criteria. Identifying the closest WTG and closest removed WTG in relation to each KOP provides a tabular understanding of how action alternatives relate to each KOP (see Appendix G). Not all KOPs were evaluated for all action alternatives. The orientation of specific KOPs in relation to action alternatives was reviewed and selected for further analysis based on the geographic proximity of each action alternative.

Affected environment: Three distinct visual settings occur within the GAA and are categorized into OCAs, SCAs, and LCAs based on their inherent physical and built characteristics. These character areas aid in understanding the types of sensitive viewers and locations along with uses that occur within the GAA. The

OCA includes approximately 6,113 square miles of open ocean environment, which includes state waters (shoreline to 3 nm from shoreline) and federal waters (3 nm from shore and beyond) within the GAA. The OCA consists of the Atlantic Ocean and interconnected bodies of water such as Rhode Island Sound, Block Island Sound, Narragansett Bay, Fisher's Island Sound, Buzzards Bay, Mount Hope Bay, Vineyard Sound, Nantucket Sound, and other bays and coves. Depending on weather conditions, the texture of the ocean surface can range from smooth to choppy, and its color can range from blue, to silver, to dark gray. The ocean within the GAA can be categorized as a working water landscape that supports a variety of uses and associated human-made features, including recreational and commercial fishing, commercial shipping, ferry transportation, pleasure boating, and associated maritime activities and features (buoys, channel markers, warning lights, etc.) (EDR 2023). Within the GAA, SCAs and LCAs have been combined to include the land area inland from the ocean edge based on best available data sources and general descriptive characteristics using landscape similarity zone information from the VIA. SLVIA tables for each action alternative in Appendix G have landscape similarity zones from the VIA categorized as SCAs and LCAs based on descriptive characteristics and with SLVIA metrics applied as appropriate. The total land area associated with the SCA and LCA as described in the following narrative accounts for roughly 1,488 square miles within the GAA and is used for comparison purposes related to the visibility of alternatives (see Appendix G).

Areas that can be considered SCAs consist of Long Island; Block Island; Conanicut Island; Cuttyhunk Island; Prudence Island; Aquidneck Island; the Elizabeth Islands; Martha's Vineyard; Nantucket; and several smaller islands scattered along the coast of Connecticut, Massachusetts, and Rhode Island. Topography is typically undulating to gently rolling, with dunes and/or steep bluffs occurring along shorelines. Elevations range from sea level to a maximum of approximately 600 feet amsl near West Greenwich, Rhode Island. Cuttyhunk Island, Block Island, and Long Island have high points ranging from 130 to 200 feet amsl. Vegetation is typically characterized by a mix of scrub forest, grassy dunes, salt marshes, freshwater wetlands, and open fields (agricultural and successional). LCAs within the GAA consist of Connecticut, Rhode Island, and Massachusetts (mainland New York does not occur within the GAA) and are categorized by low hills, and valleys are primarily forested with scattered freshwater lakes, ponds, and occasional agricultural land. Residential and urbanized development occurs throughout the LCAs and consists of seasonal and year-round homes, villages, roads, and ports, with the highest density found in villages and towns. Outside of the village and town center areas, inland development is more scattered at a lower density and is in a largely forested landscape (EDR 2023).

The VIA (EDR 2023) located in COP Appendix U3 further categorizes the above visual settings into landscape similarity zones, which are based on the similarity of landscape character and visual features such as landform, vegetation, and water and land use patterns such as recreation, residential and commercial development, and transportation. Descriptions of each of the 17 landscape similarity zones identified within the GAA can be found in the VIA (EDR 2023:15–25).

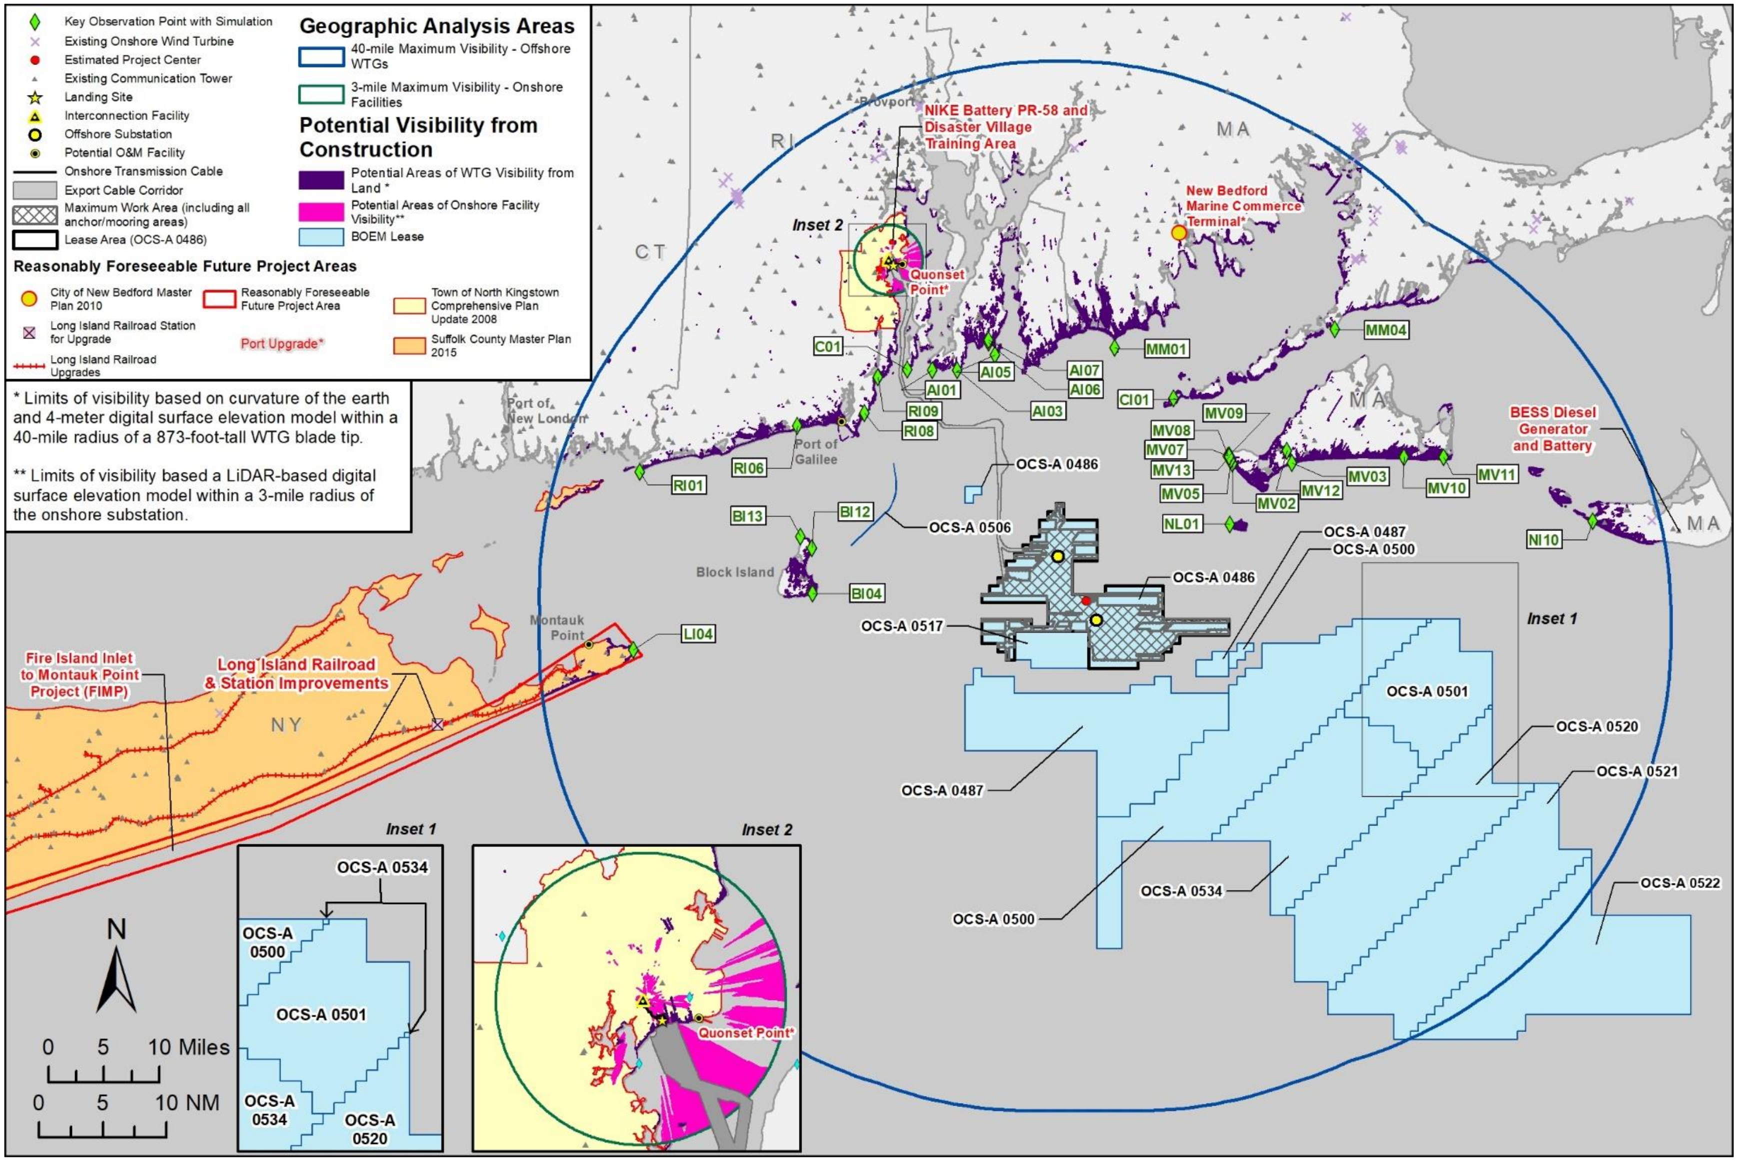

Figure 3.20-1. Geographic analysis areas for visual resources.

Viewers within the GAA have been categorized into five general user groups (local residents, through-travelers, tourists and vacationers, recreational users, and the fishing community [recreational and commercial]) based on their relative viewer experience within the GAA and their perceived sensitivity to visual changes in the landscape. Local residents are those who live, work, and travel for their daily business within the GAA. They generally view the landscape from their yards, homes, local roads, and places of employment. Residents' sensitivity to visual quality is variable, and how they experience their surroundings on a day-to-day basis is based on the location and or locations they visually interact with either in residential, workplace, or recreational settings. Through-travelers are typically vehicle-based and moving, thus having a relatively narrow field of view oriented along the axis of the roadway, and are most often destination-oriented, viewing the landscape either from the driver or passenger perspective. Through-travelers who are not residents of the area or vacationers are unlikely to be particularly sensitive to visual change and often engage with visual experiences at that time and place rather than over a consistent period of time where visual change can be more noticeable. Tourists and vacationers consist of out-of-town visitors and seasonal-weekend residents who come to the area to experience its scenic and recreational resources. Tourists and vacationers in the area are generally involved in outdoor recreational activities in settings where the experience can be directly connected to the activity or location, such as parks, trails, and beaches, and in natural settings such as forests, dunes, and the ocean.

Recreational users are generally considered to have relatively high sensitivity to aesthetic quality and changes in landscape character. Information regarding the types of recreation for both onshore and offshore users is described in Section 3.18. The fishing community is represented by recreational and commercial fishermen who work in and experience the coastal and open ocean environment on a regular basis. Despite the focused activity associated with harvesting seafood, the fishing community is particularly sensitive to changes to the visual seascape because there is often nothing in the immediate environment except for open ocean and horizon. The fishing community can have prolonged visual exposure to the open ocean, seascape, and coastal environment, in which fleets spend hours to days setting gear and harvesting fish. Those who use the ocean recreationally (e.g., boating, whale watching, sightseeing) and commercially (e.g., fishing, commercial transportation) are distinct user groups that would have foreground and middle ground views of the Project, whereas the other user groups are largely land-based and restricted to background and extended background views (EDR 2023).

## 3.20.2 Environmental Consequences

### 3.20.2.1 Relevant Design Parameters, Impact-Producing Factors, and Potential Variances in Impacts

The PDE provides for a range of WTGs sized from 8 to 12 MW. The analysis of impacts to visual resources is based on the PPAs being met using 648-foot 8-MW WTGs. This would result in a total of up to 100 WTGs and up to two OSSs for a total of 102 structures in the Lease Area.

If Revolution Wind instead installs sixty-four 12-MW WTGs, the maximum height of the blade tip for WTGs would be 873 feet above the surface compared to 648 feet for the 8-MW WTGs. Because the WTGs would exceed 699 feet, BOEM guidance, consistent with FAA requirements, would require additional mid-tower lighting in addition to lighting at the top of the nacelle (BOEM 2019). BOEM guidance further recommends that lighting color be of a red infrared wavelength between 675 and 900 nanometers based on LED light sources and that red flashing lights flash simultaneously at 30 flashes per minute (BOEM 2019). Although the 12-MW WTG option would reduce the number of WTGs, the 226-

foot taller WTGs and additional lighting would be similar in contrast in the seascape character and potentially would result in greater visual impacts within the GAA associated with the viewers' visual experience, as the WTGs may be visible at greater distances in comparison with the 8-MW WTGs.

See Appendix E1 for a summary of IPFs associated with visual resources across all action alternatives. IPFs that are either not applicable to the resource or determined by BOEM to have a negligible adverse effect are excluded from Chapter 3 and provided in Table E2-11 in Appendix E1. Offshore and onshore IPFs are addressed separately in the analysis if appropriate for the resource; not all IPFs have both an offshore and onshore component. Where feasible, calculations for specific alternative impacts are provided in Appendix E4 to facilitate reader comparison across alternatives.

Table 3.20-1 provides a summary of IPF findings carried forward for analysis in this section. Each alternative analysis discussion consists of the construction and installation phase, the O&M phase, the decommissioning phase, and the cumulative analysis. If these analyses are not substantially different, then they are presented as one discussion.

A detailed analysis of the Proposed Action is provided following the table. A detailed analysis of other considered action alternatives is also provided below the table if the analysis indicates that the alternative(s) would result in substantially different impacts than the Proposed Action. Analysis findings that identify an action alternative (C, D, E, F, or G) that has the greatest potential for reduced visual impacts (least impactful) as a result of the removal of turbines in relation to KOPs or character areas have been carried forward in Table 3.20-1 in lieu of describing impacts for all action alternatives. Overall SLVIA impact summaries for KOPs, SDAs, and character areas are provided in Tables 3.20-2 through 3.20-4. Further details and information related to all action alternatives are comprehensively compiled in Appendix G. The Conclusion section within each alternative discussion includes rationale for the effects determinations.

Under all action alternative configurations (options), overall impacts to non-historic visual resources from any alternative would range from long term **negligible** to **major** adverse for KOPs, SDAs, and character areas related to the overall visual change and magnitude of change based on analysis findings that indicate the largest number of overall impact determinations. Individual KOPs where sensitivity may influence impacts such as tribal concerns or recreation associated with scenic beaches may indicate higher impacts and are individually identified in Appendix G. Impacts would be substantial, but the resource would recover completely when the impacting agents are removed.

*This page intentionally left blank.*

**Table 3.20-1. Alternative Comparison Summary for Visual Resources**

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTGs | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
|---|---|---|---|---|---|---|---|
| Light | **Offshore**: Development of offshore wind lease areas would increase the amount of offshore light sources associated with construction and installation, O&M, and decommissioning during the life of future projects. Lighting associated with night construction and decommissioning for future projects would be localized and temporary. However, light sources, depending on quantity, intensity, and location, could be visible from unobstructed onshore and offshore KOPs based on viewer distance.<br>The existing offshore wind lease areas, following established grid spacing guidelines within the RI/MA and MA WEAs, have space for up to an estimated 936 WTGs. BOEM lighting guidelines require a minimum of three red flashing lights at the midsection of each tower and one at the top of each WTG nacelle. The potential full build-out of the existing offshore wind lease areas could result in up to 936 WTGs with lighting and would have long-term **minor** to **major** adverse impacts to onshore and offshore KOP distance and angle of view, assuming no obstructions.<br>Under the No Action Alternative, visual resource impacts would be short term during construction and long term during O&M, with **negligible** to **major** adverse impacts to KOPs, character areas, and SDAs based on the observed warning light distances discussed in Section 3.20.2.2.2. Impacts to nighttime seascape character would also be short term during construction and long term during O&M, with **negligible** to **major** adverse impacts based on the relationship of the lease areas inherent nighttime visual characteristics and | **Offshore**: The Proposed Action would require nighttime lighting for construction vessels traveling and working within the Lease Area, as well as the addition of warning lighting systems at each WTG and OSS during an 8-month construction period. This lighting could be visible and impact the viewer's nighttime visual experience and inherent nighttime seascape character. Nighttime visibility of warning lighting may be perceived anywhere from approximately 23.3 nm (26.8 miles) to 31.3 nm (36 miles) from the viewer or farther. During construction, visual impacts to the viewer's nighttime visual experience and inherent nighttime character would be temporary when associated with vessel traffic and construction lighting. These impacts would be **negligible** to **major** adverse based on viewer distance and existing night sky environment. Aquinnah Overlook (MV07), the closest occupied KOP to the Proposed Action, is located approximately 11.10 nm (13.7 miles) distant. The farthest KOP from the Proposed Action, Madeaket Beach (NI10), is located approximately 30.0 nm (34.6 miles) distant. These two KOPs are the representative minimum and maximum KOP distances in relation to perceivability of warning lighting. KOP distances in relation to the nearest WTG are described in Appendix G.<br>During O&M, the Proposed Action would contribute to nighttime lighting due to required warning lighting on up to 100 WTGs and two OSSs. Revolution Wind has committed to implementing ADLS as an EPM to reduce the duration of lighting impacts associated with the Project.<br>Because of the limited duration and frequency of anticipated warning lighting activations with ADLS and the visibility of warning lighting, the Proposed Action would result in short duration, long-term intermittent **negligible** impacts when lights are off to **major** adverse impacts to KOPs and character areas when lights are activated. Not all KOPs or character areas would experience the same level of impact due to variances in atmospheric conditions and natural and physical barriers to the view. | **Offshore**: No measurable change from Proposed Action construction impacts is anticipated under Alternatives C through F because the number and duration of construction vessels and work areas requiring nighttime lighting, as well as the assembly of WTGs and associated OSS warning lighting, would result in temporary long-term **negligible** to **major** adverse impacts based on viewer distance and existing night sky condition, similar to the Proposed Action.<br>Alternatives C through F would reduce nighttime O&M lighting by a range of 7% to 43%, across the alternative scenarios, as compared to the maximum-case scenario for the Proposed Action due to required warning lighting of fewer WTGs. Alternative D1+D2+D3 would have the greatest reduction of lighting-related impacts within the northeastern and northwestern portions of the Lease Area, which are in closest proximity to more KOPs. Impacts associated with Alternative D1+D2+D3 would be **negligible** to **minor** adverse based on viewer distance (see Section 3.20.2.2.2) and the existing night sky environment, and given this, it would have the fewest impacts to visual resources collectively. KOP distances in relation to WTGs are described in Appendix G.<br>Offshore construction activities would add new WTGs and two OSSs as compared to the No Action Alternative. Construction vessels would employ navigational safety lighting, and offshore structures would employ aviation and navigation hazard lighting. Lighting from Alternatives C through F would contribute to an approximately 6% to 10% increase in lighting sources from past, present, and reasonably foreseeable future projects within the GAA. Cumulatively, when combined with other past, present, and reasonably foreseeable projects, Alternatives C through F would result in long-term **negligible** adverse impacts when lights are off to **major** adverse impacts when lights are activated on nighttime viewers and the existing night sky environment, with Alternative E1 having the greatest contribution to reducing cumulative lighting impacts. | | | | **Offshore**: Similar to Alternatives C through F, no measurable change from construction impacts under Alternative G is anticipated because the number and duration of construction vessels and work areas requiring nighttime lighting, as well as the assembly of WTGs and associated OSS warning lighting, would result in temporary long-term **negligible** to **major** adverse impacts based on viewer distance and existing night sky condition, similar to the Proposed Action.<br>Alternative G would reduce nighttime O&M lighting by 23.5% to 42.4%, as compared to the maximum-case scenario for the Proposed Action, due to required warning lighting of fewer WTGs. Alternatives G2 and G3 would have the greatest reduction of lighting-related impacts within the northern, northeastern, and southwestern portions of the Lease Area, which are in proximity to KOPs associated with Rhode Island, Martha's Vineyard and Block Island.<br>Impacts associated with Alternatives G2 and G3 would be **negligible** to **minor** adverse based on viewer distance (see Section 3.20.2.2.2) and the existing night sky environment, and given this, they would have the fewest impacts to visual resources collectively. KOP distances in relation WTGs are described in Appendix G.<br>Similar to Alternatives C through F, offshore construction activities would add new WTGs and two OSSs to the No Action Alternative. Construction vessels would employ navigational safety lighting, and offshore structures would employ aviation and navigation hazard lighting. Lighting from Alternative G would contribute to an approximately 7.5% (Alternatives G1, G2, and G3) to 9% (Alternative G) increase in lighting sources from past, present, and reasonably foreseeable future projects within the GAA. Cumulatively, when combined with other past, present, and reasonably foreseeable projects, Alternative G would result in long-term |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTGs | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
|---|---|---|---|---|---|---|---|
| | projects' inconsistences with those nighttime characteristics. After decommissioning, the adverse impacts associated with O&M would cease. | Impacts during decommissioning would be similar to the impacts during construction and installation: long term, short duration, and intermittent **negligible** to **major** adverse.<br>Lighting from the Proposed Action would add up to 102 in-water structures to the lighting impacts from past, present, and reasonably foreseeable future projects (assumed to be up to 893 structures) for a combined total of up to 995 lighted structures within the GAA, a 11% increase in lighting compared to the No Action Alternative (Table E4-1). Nighttime vessel and construction area lighting during construction of the Proposed Action would be limited in duration and cease when construction is complete. Atmospheric and environmental conditions would influence visibility and perceivability from KOPs, character areas, and SDAs. Cumulatively, when combined with other past, present, and reasonably foreseeable projects, the Proposed Action would result in long-term **negligible** adverse impacts when lights are off to **major** adverse impacts to nighttime viewers and the existing night sky environment when lights are activated. | | | | | **negligible** adverse impacts when lights are off to **major** adverse impacts when lights are activated on nighttime viewers and the existing night sky environment, with Alternatives G1, G2, and G3 having the greatest contribution to reducing cumulative lighting impacts based on the number of associated WTGs (65) and OSSs (two). |
| | **Onshore**: Future onshore components of offshore projects could require OnSSs, ICFs, O&M facilities, and port upgrades depending on project needs and could introduce additional or new infrastructure elements into SCAs and/or LCAs. However, specific locations and project designs have not been determined. Infrastructure and associated nighttime lighting to support other offshore wind projects (e.g., OnSS or O&M facilities) are anticipated to occur in areas of existing development or where similar infrastructure and development exist to aid in co-location of similar resources. Therefore, additional onshore nighttime lighting sources associated with infrastructure to support future offshore wind projects would be a noticeable change over time and would have long-term **negligible** to | **Onshore**: Light and noise from onshore construction activities could temporarily adversely impact viewers if located near the landing site, onshore cable route, or proposed onshore facilities. It is assumed that construction activities would occur during daylight hours. Fifteen publicly accessible KOPs were identified in the Visual Resource Assessment and Historic Resources Visual Effects Analysis within 3 miles of the OnSS and ICF with the closest at approximately 0.6 mile (Narraganset Bay) (EDR 2021). Impacts to these KOPs are not anticipated due to distance, intervening vegetation, and existing lighting sources. Approximately 500 feet south and west of the OnSS and ICF are residential properties consisting of single-family and multifamily residences. Dense stands of tall trees (40 feet tall on average) provide a natural buffer between the OnSS and ICF and the residences, which is anticipated to reduce any nighttime-related impacts to nearby residences to **negligible** adverse. | **Onshore:** Alternatives C through F would not alter impacts from onshore activities; therefore, impacts would be the same as those described for the Proposed Action: temporary **negligible** to **minor** adverse to potential nighttime viewers and the existing night sky environment based on viewer location and perspective in relation to existing onshore light sources. | | | | **Onshore:** Similar to Alternatives C through F, impacts associated with Alternative G would be the same as the Proposed Action: temporary **negligible** to **minor** adverse to potential nighttime viewers and the existing night sky environment based on viewer location and perspective in relation to existing onshore light sources. |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTGs | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
|---|---|---|---|---|---|---|---|
| | **moderate** adverse impacts for the life of the projects. | Onshore lighting related to construction activity for the O&M facility, located within an existing industrial use area with existing lighting, would create short-term **negligible** adverse impacts to potential nighttime viewers and the existing night sky environment due to the nature of the construction lighting, which would be contained to the existing property and be similar in nature to surrounding facilities and light sources.<br>The nighttime lighting impacts of the OnSS, ICF, and O&M facility would cause long-term **negligible** adverse impacts to potential nighttime viewers and the existing night sky environment during Project O&M. Impacts associated with the OnSS and ICF would be reduced by the use of switched vs. motion operational lighting, which would comply with local lighting regulations. Impacts associated with the O&M facility would be associated with localized light sources and operational uses, similar to surrounding infrastructure.<br>Onshore construction and installation would add an O&M facility, OnSS, and ICF to the No Action Alternative. These onshore structures and nighttime lighting sources are anticipated to occur in areas of existing development or where similar infrastructure and development exists. Therefore, when considered cumulatively with past, present, and reasonably foreseeable activities, the Proposed Action would result in long-term **negligible** adverse impacts to nighttime viewers and the existing night sky environment. | | | | | |
| Presence of structures | **Offshore**: Based on the Proposed Action and action alternatives analysis findings (Section 3.20.2.2 and Appendix G), if future offshore wind projects are implemented, the effects of installed WTGs and associated infrastructure on KOPs, character areas, and SDAs, when viewed from both onshore and offshore locations, would result in long-term **negligible** to **major** adverse visual impacts. The impacts experienced at KOPs, character areas, and SDAs would be dependent upon distance and orientation to the project, the degree of visibility considering lighting and | **Offshore**: The addition of Project structures with navigation and aviation lighting over the 8-month construction period, coupled with the temporary increase and concentration in construction related vessel activity, would result in short-term to long-term **negligible** to **major** adverse impacts to KOPs. Sixteen of the 37 KOPs would experience major adverse impacts. Impacts to SDAs would range from **negligible** to **major** adverse with approximately 30,208 acres of visibility or 15.5 % of the approximately 208,009 acres of SDAs. Impacts to the OCA as a result of the construction activities noted above would be **major** adverse (approximately 5,882 square miles or 96.2 % of the total OCA within the GAA would have views of the | **Offshore**: The layout and construction activities proposed under Alternatives C through F would include the same activities and construction sequencing as the Proposed Action and would result in similar anticipated impacts. Therefore, the construction and installation of offshore Project structures would have long-term **negligible** to **major** adverse impacts to KOPs, character areas, and SDAs under Alternatives C through F, similar to those of the Proposed Action.<br>Alternatives C1 and C2: Because of the placement of WTGs, Alternative C1 would result in fewer impacts to KOPs than Alternative C2. Alternative C1 would result in short-term to long-term **negligible** to **major** adverse impacts to KOPs within the GAA, with 7 of the 17 selected KOPs having major adverse impacts, five KOPs having moderate adverse impacts, and three KOPs having minor adverse impacts. Impacts to SDAs would range from **negligible** to **major** adverse, with approximately 29,968 acres of visibility of Alternative C2 (14.4%) of the approximately 208,009 acres of SDAs as compared to 30,059 acres of Alternative C1. Impacts to the OCA would be **major** adverse, similar to other action alternatives, with Alternatives C1 and C2 visible to approximately 96% of the OCA. Impacts to SCAs and LCAs would range from | | | | **Offshore**: Similar to Alternatives C through F, the layout and construction activities proposed under Alternatives G would include the same activities and construction sequencing as the Proposed Action and would result in similar anticipated impacts. Therefore, the construction and installation of offshore Project structures would have long-term **negligible** to **major** adverse impacts to KOPs, character areas, and SDAs under Alternatives G, similar to those of the Proposed Action<br>Because of the placement of WTGs in relation to KOPs, Alternatives G2 and G3 would have the greatest reduced visual impact as |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action)<br>up to 100 WTGs | Alternative C<br>(Habitat Alternative)<br>64–65 WTGs | Alternative D<br>(Transit Alternative)<br>78–93 WTGs | Alternative E<br>(Viewshed Alternative)<br>64–81 WTGs | Alternative F<br>(Higher Capacity Turbine Alternative)<br>56 WTGs | Alternative G<br>(Preferred Alternative)<br>65 WTGs |
|---|---|---|---|---|---|---|---|
| | atmospheric conditions, and the perceivable contrast, dominance, and scale of WTGs and OSSs along the horizontal plane of the ocean. | Proposed Action. Impacts to SCAs and LCAs would range from **minor** to **moderate** adverse based on the sensitivity and degree of magnitude in relation to the character area; overall approximately 35 square miles (2.4 %) of the combined SCAs and LCAs would have visibility of the Project within the GAA. Of the 60 impact determinations associated with KOPs, character areas, and SDAs associated with the Proposed Action, 21 major, 21 moderate, 11 minor and 7 negligible impacts were determined. Further information related to impacts associated with the Proposed Action is located in Appendix G. Further information related to impacts associated with the Proposed Action is located in Appendix G (see Tables G-VIS1a through G-VIS2e).<br>WTGs would be more visually apparent viewed from the northern and easterly shorelines of Rhode Island and Massachusetts. The up to 100 WTGs and two OSSs would become less perceivable as the distance from KOPs and/or character areas increases. Atmospheric and environmental factors such as haze, sun angle, time of day, cloud cover, fog, sea spray, and wave action would also influence visibility and perceivability from KOPs (e.g., NI10 - modified haze/sun, MV12 day vs. night, MV05 day vs. night), which may not be depicted in all visual simulations, or from other non-simulated locations that may have visibility within character areas. It is anticipated therefore that Project O&M would result in long-term **negligible** to **major** adverse impacts.<br>The Proposed Action would add up to 100 WTGs and two OSSs to the No Action Alternative. As a result, approximately 90% of the total potential WTGs and OSSs in the GAA (up to 995) would be associated with other future offshore wind development projects beyond the Proposed Action and at distances from KOPs, character areas, and SDAs where atmospheric conditions and curvature of the Earth influence visibility. When combined with other past, present, and reasonably foreseeable projects, the Proposed Action would result in long-term **negligible** to **major** adverse cumulative impacts to KOPs, character areas, and SDAs. Adverse impacts would be removed at Project decommissioning. | **minor** to **moderate** adverse based on the sensitivity and degree of magnitude in relation to the character area; overall, Alternative C2 would be visible to approximately 34.7 square miles (2.3%) of the combined SCAs and LCAs within the GAA. Because of the similarity in placement of WTGs, Alternatives C1 and C2 would result in similar impacts, and both alternatives would result in fewer impacts than the Proposed Action. Of the 40 impact determinations associated with KOPs, character areas, and SDAs, 10 major, 14 moderate, seven minor, and five negligible adverse impacts were determined for Alternative C1 (see Tables G-VIS3 and G-VIS4c).<br>Alternative D alternatives: Of the seven Alternative D alternatives, Alternative D1+D2+D3 would result in the fewest number of adverse impacts because of the combination of removed turbines within the Lease Area as compared to the maximum-case scenario for the Proposed Action. Alternative D1+D2+D3 would result in short-term to long-term **negligible** to **major** adverse impacts to KOPs within the GAA, with 12 of the 37 selected KOPs having major adverse impacts, 14 KOPs having moderate adverse impacts, and 11 KOPs having minor to negligible adverse impacts. Impacts to SDAs would range from **negligible** to **major** adverse, with approximately 28,840 acres of visibility of Alternative D1+D2+D3 (13.9%) of the approximately 208,009 acres of SDAs. Impacts to the OCA would be **major** adverse, similar to other action alternatives, with the Project visible to approximately 96% of the OCA. Impacts to SCAs and LCAs would range from **minor** to **moderate** adverse, similar to the Proposed Action based on the sensitivity and degree of magnitude in relation to the character area. Overall, approximately 31.1 square miles (2.1%) of the combined SCAs and LCAs would have visibility of Alternative D1+D2+D3 within the GAA. Of the 60 impact determinations associated with KOPs, character areas, and SDAs, 15 major, 24 moderate, 12 minor, and nine negligible adverse impacts were determined for Alternative D1+D2+D3 (see Tables G-VIS5a and G-VIS6c).<br>Alternatives E1 and E2: Because of the placement of WTGs, Alternative E1 would result fewer impacts than Alternative E2. Alternative E1 would result in short-term to long-term **negligible** to **major** adverse impacts to KOPs within the GAA, with four of the 21 selected KOPs having major adverse impacts, 12 KOPs having moderate adverse impacts, and five KOPs having minor to negligible adverse impacts. Impacts to SDAs would range from **negligible** to **major** adverse, with approximately 29,085 acres of visibility of Alternative E1 (14.0%) of the approximately 208,009 acres of SDAs. Impacts to the OCA would be **major** adverse, similar to the Proposed Action, with the alternative visible to approximately 96% of the OCA. Impacts to SCAs and LCAs would range from **minor** to **moderate** adverse based on the sensitivity and degree of magnitude in relation to the character area. Overall, Alternative E1 would be visible to approximately 32.7 square miles (2.2%) of the combined SCAs and LCAs within the GAA. Of the 44 impact determinations associated with KOPs, character areas, and SDAs, eight major, 21 moderate, seven minor, and eight negligible adverse impacts were determined for Alternative E1 (see Tables G-VIS7 and G-VIS8c for individual KOP impacts and Section 3.20.2.5 for example impact comparison).<br>Alternative E2 would result in short-term to long-term **negligible** to **major** adverse impacts to KOPs within the GAA; with one of the 16 selected KOPs having major adverse impacts, six KOPs having moderate adverse impacts, and nine KOPs having minor to negligible adverse impacts. Impacts to SDAs would range from **negligible** to **major** adverse with approximately 29,385 acres of visibility of Alternative E2 (14.1.0 %) of the approximately 195,701 acres of SDAs. Impacts to the OCA would be **major** adverse, similar to the Proposed Action, with the alternative visible to approximately 96% of the OCA. Impacts to SCAs and LCAs would range | | | | compared to the Proposed Action. Information related to Alternatives G and G1 is included in Appendix G.<br>Alternative G2 would result in a slightly lesser degree of impacts than Alternative G3. Alternative G2 would result in short-term to long-term **negligible** to **major** adverse impacts to KOPs within the GAA, with one of the 19 selected KOPs having major adverse impacts, 10 KOPs having moderate adverse impacts, and four KOPs having **minor** to **negligible** adverse impacts. Comparatively, Alternative G3 would have 10 of the 22 selected KOPs with major adverse impacts, seven KOPs with moderate adverse impacts, one KOP with minor impacts, and four with negligible adverse impacts.<br>Impacts to SDAs would range from **negligible** to **major** adverse for Alternative G, with Alternative G2 having the greatest reduced visibility with approximately 30,499 acres of visibility (14.6%) of the approximately 208,009 acres of SDAs as compared to 30,477 acres of visibility (14.7%) associated with Alternative G3. Impacts to the OCA would be major adverse, similar to other action alternatives, with Alternative G visible to approximately 96% of the OCA.<br>Impacts to SCAs and LCAs would range from **minor** to **moderate** adverse based on the sensitivity and degree of magnitude in relation to the character area; overall, Alternative G3 would be the least visible to approximately 33.4 square miles (2.2%) of the combined SCAs and LCAs within the GAA as compared 33.5 square miles (2.3%) associated with Alternative G2.<br>Of the 42 impact determinations associated with KOPs, character areas, and SDAs, six major, 19 moderate, eight minor, and nine negligible adverse impacts were determined for Alternative G2 as compared to 10 major, seven moderate, one minor, and four negligible adverse impacts associated with Alternative G3 (see Tables G-VIS9 to G-VIS10c). |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTGs | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
|---|---|---|---|---|---|---|---|
| | | | from **minor** to **moderate** adverse based on the sensitivity and degree of magnitude in relation to the character area. Overall, Alternative E2 would be visible to approximately 33.5 square miles (2.3%) of the combined SCAs and LCAs within the GAA. Of the 39 impact determinations associated with KOPs, character areas, and SDAs, five major, 15 moderate, seven minor, and 12 negligible adverse impacts were determined for Alternative E2 (see Tables G-VIS7 and G-VIS8c).<br>Alternative F: Alternative F, when combined with other action alternatives, could reduce the number of WTGs installed in the Lease Area by 7% to 44% as compared to the maximum potential 100 WTGs installed under the Proposed Action. The potential reduction of impacts would depend on viewer distance and would be focused primarily on locations in closest proximity to the area of reduced WTGs. A reduction in WTGs installed would be expected to result in long-term **negligible** to **major** adverse impacts to KOPs, character areas, and SDAs. However, the application of Alternative F cannot be fully evaluated until the specific WTGs to be removed are identified.<br>Further information related to impacts associated with Alternatives C, D, and E is included in Appendix G.<br>Alternatives C through F would add between 66 and 83 structures (WTGs and OSSs) to the estimated up to 893 structures under the No Action Alternative within the GAA. Of the four action alternatives identified as resulting in the greatest reduction of impacts, Alternative D1+D2+D3 would result in the smallest area of visibility (approximately 31 square miles of SCA and LCA). Alternative D1+D2+D3 when combined with other past, present, and reasonably foreseeable projects would result in long-term **negligible** to **major** adverse impacts to KOPs, character areas, and SDAs in comparison to the No Action Alternative. | | | | |
| | **Onshore**: Future onshore components of offshore wind projects could require OnSSs, ICFs, O&M facilities, and port upgrades depending on project needs and could introduce additional or new infrastructure elements into the characteristic landscape over a period of time, although specific locations and design have not been determined. Infrastructure to support other offshore wind projects (e.g., OnSS or O&M facilities) are anticipated to occur in or be co-located in areas of existing development associated with SCAs or LCAs where similar infrastructure and development exist. Therefore, the addition of onshore structures to support other offshore wind projects would be noticeable over time and would have long-term **negligible** to **minor** adverse impacts to identified KOPs, character areas, and SDAs based on their location in relation to other | **Onshore**: The construction and installation of the OnSS and ICF would occur during an approximate 18-month construction period. During this period, there would be an noticeable change over time in the immediate foreground of the OnSS and ICF because of the addition of the facilities. The O&M facility at the Port of Davisville at Quonset Point would be similar to existing industrial infrastructure, consisting of large geometric features. Therefore, the addition of Project structures associated with the OnSS, ICF, and O&M facility would create long-term **negligible** to **minor** adverse impacts to KOPs, character areas, and SDAs until the projects are decommissioned.<br>Where visible within immediate foreground distances, the OnSS and ICF would introduce new industrial-utility structures. However, the OnSS and ICF would be located adjacent to the existing Davisville Substation and would not be out of scale or character with the existing development in the vicinity, which ranges from transit rail and four-lane roadway to residential to heavy industrial within 0.5 mile. For this reason, the OnSS and ICF | **Onshore**: There are no design differences between Alternatives C through F in onshore activities; therefore, impacts resulting from onshore activities would be the same as those described for the Proposed Action: long-term **negligible** to **minor** adverse to viewers based on viewer location and perspective in relation to existing onshore structures and development as well as associated LCAs. | | | | **Onshore**: Similar to Alternatives C through F, impacts resulting from onshore activities associated with Alternative G would be the same as those described for the Proposed Action: long term **negligible** to **minor** adverse to viewers based on viewer location and perspective in relation to existing onshore structures and development as well as associated LCAs. |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTGs | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
|---|---|---|---|---|---|---|---|
| | infrastructure and facilities until the projects are decommissioned. | would result in long-term **negligible** adverse impacts to KOPs, character areas, and SDAs.<br>Onshore construction and installation would add an, ICF, and OnSS to the No Action Alternative. The O&M facility would use existing structures. The Proposed Action does not include any updates to ports. Any potential future port upgrades required to service the offshore wind industry could result in similar **negligible** adverse visual impacts to KOPs, character areas, and SDAs. The Proposed Action when combined with past, present, and reasonably foreseeable activities would result in long-term **negligible** adverse cumulative impacts to KOPs, character areas, and SDAs. | | | | | |

#### 3.20.2.2 Alternative A: Impacts of the No Action Alternative on Visual Resources

##### 3.20.2.2.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for visual resources (see Section 3.20.1) would continue to follow current regional trends and respond to IPFs introduced by other ongoing activities and by permitted and constructed offshore wind COP projects within the geographic analysis area. These IPFs are described and analyzed in Appendix E1.

##### 3.20.2.2.2 Cumulative Impacts

This section discloses potential visual resources impacts associated with future offshore wind development (without the Proposed Action). The cumulative impact analysis for the No Action Alternative for planned non-offshore wind activities, as well as activities associated with constructed or approved offshore wind projects (without the Proposed Action), is provided in Appendix E1.

**Offshore Activities and Facilities**

<u>Light:</u> Development of offshore wind lease areas would increase the amount of offshore light sources associated with construction and installation, O&M, and decommissioning during the life of future projects. Lighting associated with night construction and decommissioning for future projects within BOEM lease areas would be localized and temporary and staggered over time; therefore, the lease areas would not have light sources across the entirety of the GAA at one time. However, light sources, depending on quantity, intensity, and location, could be visible from unobstructed sensitive onshore and offshore viewing locations based on viewer distance.

Field observations associated with visibility of FAA warning lighting (warning lighting) for the BIWF were conducted in May 2019 (HDR 2019). The BIWF consists of five WTGs with a blade tip height of approximately 600 feet. Observations of FAA nighttime lighting visibility under clear sky conditions in open water identified that warning lighting may be visible to the naked eye at a distance of 23.3 nm (26.8 miles) from the viewer (HDR 2019). The approximate 27-mile distance where the BIWF hub height drops below the visible horizon due to the curvature of the Earth and WTG height and viewer position influences the overall distance from which warning lighting may be visible. The BIWF report also concludes that daytime visibility of WTGs from land and water viewing locations is strongly dependent on weather conditions and distance (HDR 2019). Research related to the visibility of onshore WTGs in western landscapes (Sullivan et al. 2012) analyzed the visibility of FAA lighting at various distances and concluded that warning lighting was visible approximately 31.3 nm (36 miles) from viewing positions in broad, uninterrupted onshore landscapes, which would be a similar viewing condition as views across the open ocean setting. Of note, warning lighting may be visible beyond 36 miles, and the aforementioned study (Sullivan et al. 2012) had intervening topography that influenced visibility at the 36-mile distance. Therefore, it is assumed based on the referenced studies that the visibility of warning lighting may be visible anywhere from 23.3 nm (26.8 miles) to 31.3 nm (36 miles) or beyond.

Warning lighting systems would be used for the duration of Project O&M following BOEM guidelines (BOEM 2021a) for each reasonably foreseeable offshore wind project (876 WTGs). The amassing of these WTGs and associated synchronized flashing strobe lights affixed with a minimum of three red flashing lights at the midsection of each tower and two at the top of each WTG nacelle within the lease areas would have long-term **minor** to **major** adverse impacts to onshore and offshore KOPs based on viewer distance and angle of view and assuming no obstructions. Atmospheric and environmental factors such as haze and fog would influence visibility and perceivability of warning lighting from viewing locations. Additionally, long-term impacts associated with OCAs, SCAs, and LCAs would range from long term **minor** to **major** adverse based on the relationship of the character areas, lease areas inherent nighttime visual characteristics, and projects' inconsistences with those nighttime characteristics. Based on warning light viewshed analyses conducted as part of the VIA (EDR 2023:64), for analysis purposes, the following thresholds are considered as part of nighttime visual impacts: minor to negligible impacts are anticipated for distances beyond approximately 26 nm (30 miles); moderate impacts are anticipated for distances between approximately 17 nm (20 miles) and 26 nm (30 miles); and major impacts are anticipated for distances from viewer position out to 17 nm (20 miles). As noted above, overall visibility is based on viewer position, atmospheric conditions, and other environmental and intervening factors.

Implementation of an ADLS is an EPM (see Table F-1in Appendix F) and a component of the Proposed Action and action alternatives. The shorter duration synchronized flashing of the ADLS (activated as needed by nearby aircraft) would have reduced visual impacts at night as compared to the standard continuous, medium-intensity red strobe FAA warning light system. It is assumed that when FAA warning lights are not activated through the use of ADLS, nighttime impacts would be **negligible**. Based on a recent study by Capital Airspace related to ADLS efficacy associated with the RWF, historic air traffic data for flights passing through the warning light activation area indicated that the ADLS would have been activated for a total of 3 hours 35 minutes and 39 seconds over a 1-year period. Considering the local sunrise and sunset times, an ADLS warning light system could result in over a 99% reduction in warning light duration as compared to a traditional continuous warning light system (see COP Appendix S4 for ADLS efficacy analysis).

Lighting impacts would be most pronounced (although for a short duration with the implementation of an ADLS) for locations that can be currently characterized as undeveloped within the seascape both from an onshore and offshore perspective, where lighting from infrastructure and activities is not dominant or perceivable by the casual observer (viewer). Therefore, visual resource impacts would be short term during construction and long term during O&M, with **negligible** to **major** adverse impacts for a short duration of time to viewers based on the observed distances as categorized under the warning lighting impacts above and the anticipated activation time over the period of 1 year. Impacts to character areas would also be short term during construction and long term during O&M, with **negligible** to **major** adverse impacts for a short duration of time based on the relationship of the character areas, the lease areas' inherent nighttime visual characteristics, and projects' inconsistences with those nighttime characteristics. After decommissioning, the adverse impacts associated with O&M would cease.

<u>Presence of structures:</u> Planned future wind facility projects would consist of an estimated 897 WTGs and OSSs (see Table E4-1 in Appendix E4). In general, under clear daytime atmospheric conditions and depending on natural lighting angles, projects built within BOEM lease areas that are within 10.4 nm (12 miles) of character areas and viewing areas would have major adverse visual impacts, viewing areas beyond 10.4 nm (12 miles) up to 20.8 nm (24 miles) would have moderate to major adverse impacts, and viewing areas beyond 20.8 nm (24 miles) up to 26 nm (30 miles) would have minor adverse impacts (BOEM 2021b). Viewing areas that exceed 26 nm (30 miles) from projects would have negligible adverse visual impacts due to distance, the curvature of the Earth, and the influence of atmospheric conditions, which would decrease the ability of the viewer to discern or perceive projects at that distance. The combined visual effects of the planned project structures to KOPs, character areas, and SDAs, when

viewed from both onshore and offshore locations, would create long-term **negligible** to **major** adverse visual impacts. The overall impacts to KOPs, character areas, and SDAs would be dependent on geographic distance, curvature of the Earth, and orientation to the project; the elevation of the viewer; the degree of visibility considering lighting and atmospheric conditions; and the perceivable contrast, dominance, and scale of WTGs and OSSs along the horizontal plane of the ocean.

### Onshore Activities and Facilities

Light: Future onshore planning projects within the GAA may require OnSSs, ICFs, O&M facilities, and port upgrades depending on project needs and may introduce additional or new infrastructure elements into SCAs and/or LCAs, although specific locations and project designs have not been determined. Infrastructure and associated nighttime lighting to support other offshore wind projects (e.g., OnSS O&M facilities) are anticipated to occur in areas of existing development or where similar infrastructure and development exist to aid in co-location of similar resources. Therefore, additional nighttime lighting sources associated with infrastructure to support other offshore wind projects would be a noticeable change over time and would have long-term **negligible** to **moderate** adverse impacts depending on the final location of infrastructure and additional lighting needs in relation to existing nighttime light sources.

Presence of Structures: Future onshore planning projects could require OnSSs, ICFs, O&M facilities, and port upgrades depending on project needs and could introduce additional or new infrastructure elements into the characteristic landscape over a period of time, although specific locations and design have not been determined. Infrastructure to support other offshore wind projects (e.g., OnSS O&M facilities) are anticipated to occur in or be co-located in areas of existing development associated with SCAs or LCAs where similar infrastructure and development exists based on trends in siting of these facilities associated with recent offshore wind projects. Therefore, the addition of structures to support other offshore wind projects would be noticeable over time and would have long-term **negligible** to **moderate** adverse impacts to identified KOPs, character areas, and SDAs depending on the final location of structures in relation to other built features in the characteristic landscape.

### 3.20.2.2.3 Conclusions

Under the No Action Alternative, BOEM would not approve the COP; Project construction and installation, O&M, and decommissioning would not occur; and potential impacts on the viewer’s visual experience and character areas associated with the Project would not occur. However, ongoing and future offshore wind activities would have continued temporary to long-term adverse impacts, primarily through construction and O&M of WTGs and associated lighting.

BOEM anticipates that the range of impacts for reasonably foreseeable offshore wind activities would be **negligible** to **major** adverse for KOPs, character areas, and SDAs. BOEM anticipates that the range of impacts for ongoing activities and reasonably foreseeable activities other than offshore wind (as described in Appendix E) are anticipated to be **negligible** to **moderate** adverse as those ongoing activities and reasonably foreseeable activities would have less prominence and dominance as compared to offshore wind projects.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the GAA combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would result in **moderate** adverse impacts because the overall effect would be substantial, but the resource would be expected to recover completely after decommissioning.

### 3.20.2.3 Alternative B: Impacts of the Proposed Action on Visual Resources

#### 3.20.2.3.1 Construction and Installation

##### Offshore Activities and Facilities

Light: The Proposed Action would require nighttime lighting for construction vessels traveling and working within the Lease Area as well as the addition of warning lighting systems at each WTG and OSS during an 8-month construction period. This lighting could be visible and impact the viewer’s nighttime visual experience and inherent nighttime seascape character. During construction, visual impacts to potential nighttime viewers and the existing night sky environment would be temporary when associated with vessel traffic and construction lighting. Impacts would be long term, of short duration, and intermittent when associated with WTGs and OSSs warning lighting implementing ADLS. These impacts would be **negligible** to **major** adverse based on the observed viewer distance, as described in Section 3.20.1.1. Aquinnah Overlook (MV07), the closest occupied KOP to the Proposed Action, is located approximately 11.10 nm (13.7 miles) from the Proposed Action and the farthest KOP, Madeaket Beach (NI10), is located approximately 30.0 nm (34.6 miles) from the Proposed Action; these KOPs are representative of the minimum and maximum KOP distances in relation to perceivability of warning lighting. KOP distances in relation to the nearest WTG are further described in Appendix G.

Presence of structures: Up to 102 Project structures (WTGs and OSSs) are proposed for installation within the GAA. As noted under the No Action Alternative, these offshore structures would impact both viewers and character areas throughout construction until build-out completion. During construction, offshore and onshore viewers would see the upper portions of tall equipment such as mobile cranes and vessels. This equipment would move from each WTG and OSS location as construction progresses and thus would be temporary fixtures. Subsequently, the construction and installation of Project structures would occur during an approximate 8-month construction period, when there would be an appreciable change over time in seascape character and the viewer’s visual experience resulting from the addition of up to two OSSs and 100 WTG structures. This appreciable change during the 8-month construction period as a result of the addition of Project structures to full build-out based on the WTG installation sequence; the temporary increase and concentration in vessel activity associated with construction, installation, and transport activities; and the addition of navigational marking and lighting would create short-term to long-term **negligible** to **major** adverse impacts to KOPs, with 16 of the 37 KOPs having major impacts. Impacts to SDAs would range from **negligible** to **major** adverse, with approximately 30,208 acres of visibility of the Proposed Action, or 14.5%, of the approximately 208,009 acres of SDAs. Impacts to the OCA as a result of the construction activities noted above would be **major** adverse (approximately 5,882 square miles, or 96.2%, of the total OCA within the GAA would have views of the Proposed Action). Impacts to SCAs and LCAs would range from **minor** to **moderate** adverse based on the sensitivity and degree of magnitude in relation to the character area; overall, the Project would be visible to approximately 35 square miles (2.4%) of the combined SCAs and LCAs within the GAA. Of the 60 impact determinations associated with KOPs, character areas, and SDAs, 21 major, 21 moderate, 11 minor, and seven negligible adverse impacts were determined for the Proposed Action. Further information related to impacts associated with the Proposed Action is located in Appendix G (see Tables G-VIS1a thru G-VIS2e).

### Onshore Activities and Facilities

Light: Light from onshore construction activities could temporarily adversely impact viewers if located near the landing site, onshore cable route, and proposed onshore facilities. It is assumed that construction activities would occur during daylight hours. Fifteen publicly accessible KOPs were identified in the Visual Resource Assessment and Historic Resources Visual Effects Analysis within 3 miles of the OnSS and ICF, with the closest at approximately 0.6 mile distant (Narraganset Bay) (EDR 2021). Based on aerial imagery, approximately 500 feet south and west of the OnSS and ICF, there are residential properties consisting of single-family and multifamily residences. However, dense stands of tall trees, approximately 40-feet tall or greater, provide a natural buffer (approximately 300–350 feet thick) between the OnSS and ICF and the residences, which is anticipated to reduce any potential nighttime-related impacts to nearby residences to **negligible** adverse.

Nighttime lighting associated with the O&M facility at the Port of Davisville at Quonset Point would be localized (consisting of temporary nighttime safety and security lighting) because construction activities would occur during daylight hours. Based on viewer location and perspective in relation to existing onshore light sources, onshore lighting related to construction activity for the O&M facility would create short-term **negligible** adverse impacts to potential nighttime viewers and the existing night sky environment. Impacts associated with O&M facility would be associated with localized light sources associated with the facility and operational uses, similar to surrounding infrastructure.

Presence of structures: A new OnSS and ICF would be constructed to support interconnection of the Project to the existing electrical grid. Vegetation clearing associated with the access road and taller equipment (e.g., crane tip) may be visible from Camp Avenue or from surrounding residences during construction of these onshore structures. The construction and installation of the OnSS and ICF would occur during an approximate 18-month construction period. During this period, there would be a noticeable change over time in the immediate foreground of the OnSS and ICF because of the addition of the facilities. However, viewers would generally be screened and have obstructed views of construction activities because of the presence of existing development combined with densely forested areas that surround the facilities (EDR 2021).

The O&M facility at the Port of Davisville at Quonset Point would consist of two structures to house office space (approximately 1,000 square feet) and storage space (approximately 11,000 square feet) and located on the existing Air National Guard base. The structures, which are to be refurbished existing facilities, would be similar to existing industrial infrastructure, consisting of large geometric features. Therefore, the noticeable change during the 18-month construction period as a result of construction and installation activities and the addition of Project structures associated with the OnSS, ICF, and O&M facility would create long-term **negligible** adverse impacts to KOPs, character areas, and SDAs based on viewer location and perspective in relation to existing onshore structures and development.

#### 3.20.2.3.2 Operations and Maintenance and Decommissioning

### Offshore Activities and Facilities

Light: During O&M, the Proposed Action would contribute to nighttime lighting due to required warning lighting of up to 100 WTGs and two OSSs. During times when the warning lighting is activated, this lighting would add a developed-industrial visual element to views that were previously characterized by dark, open ocean. The addition of the ADLS would result in shorter duration night sky impacts to KOPs, character areas, and SDAs. Because of the limited duration and frequency of anticipated aviation warning activations and visibility of warning lighting, the Proposed Action would result in long-term, short duration, intermittent **negligible** to **major** adverse impacts to KOPs, character areas, and SDAs within distances described above. Impacts during decommissioning would be similar to the impacts during construction and installation: long term, short duration, and intermittent **negligible** to **major** adverse.

Presence of structures: The offshore components of the Project would be visible from coastal locations in New York, Connecticut, Rhode Island, and Massachusetts. Based on visual simulations as part of the VIA, the WTGs and/or OSSs would be all or partially visible on the horizon from shore where there are generally unobstructed views within the analysis area from 28 of the 37 KOPs evaluated (EDR 2023). The WTGs and OSSs would be painted RAL 9010 Pure White or RAL 7035 Light Grey in accordance with BOEM guidelines. The effects of sun lighting, shade, and shadows would cause backlit contrasts and higher impacts for onshore and offshore views from the northeast, north, and northwest in relation to sun angle. The color contrast varies due to sun angles and atmospheric clarity shifting from white WTGs against a blue or gray backdrop to a dark gray WTG against a light gray backdrop. Distance between the viewer and the WTGs along with the curvature of the Earth affect how much of the WTG is visible from viewer locations and influence its visible scale and dominance.

The up to 100 WTGs and two OSSs, as shown in the visual simulations in COP Appendix U3 (EDR 2023), would be viewed from variable distances along the ocean horizon depending on their distance from the 37 KOPs (7.6 nm [8.7 miles] minimum [it should be noted that this minimum distance was measured from Nomans Land Island which is an uninhabited island and National Wildlife Refuge] to 30 nm [34.6 miles] maximum) and result in variable degrees of impacts. Additionally, the curvature of the Earth, which influences the percentage of the turbine structure visible along the horizon is also a factor in the overall impacts. The WTGs would be more visually apparent when viewed from the northern and easterly shorelines due to the relationship of the Lease Area to KOPs (e.g., KOP MV02), which are approximately 11.8 nm (13.6 miles) distant. The scale of the 100 WTGs and two OSSs would become less perceivable as the distance from KOPs and/or character areas increases. Atmospheric and environmental factors such as haze, sun angle, time of day, cloud cover, fog, sea spray, and wave action would also influence visibility and perceivability from KOPs (e.g., NI10 - modified haze/sun, MV12 day vs. night, MV05 day vs. night), which may not be depicted in all visual simulations, or from other non-simulated locations that may have visibility within character areas. As a result, O&M would cause long-term **negligible** to **major** adverse impacts for the life of the Project. Impacts from decommissioning the 100 WTGs and two OSSs would be similar to construction impacts, **negligible** to **major** adverse.

### Onshore Activities and Facilities

Light: Impacts would be reduced by the developer-committed EPM of switched vs. motion operational lighting, which would comply with local lighting regulations. Facility lighting would be mounted with the lamp horizontal to the ground (light facing straight down) or with a lamp tilt no more than 25 degrees from the horizon, which would direct light sources downward and localize any light disturbance (VHB 2023). Because of the similarity of the existing lighting of the adjacent Davisville Substation with the OnSS and ICF (lighting masts assumed to be approximately 20 feet in height), screening by mature vegetation throughout the area as noted in Section 3.20.2.2.1, and developer-committed EPMs, the nighttime lighting impacts of the OnSS and ICF would cause long-term **negligible** adverse impacts to potential nighttime viewers. Impacts during decommissioning would be similar to the impacts during construction and installation, short-term **negligible** to **minor** adverse.

Presence of structures: Based on the results of the viewshed analysis (EDR 2023), the OnSS and ICF infrastructure (buildings, lighting protection, and transmission structures) could be visible from approximately 15% (approximately 2,928 acres) of the 3-mile visual study area not accounting for the influence of vegetative screening defined in the onshore VIA. The presence of existing intervening landscape vegetation along roadways and other viewing locations could further reduce the extent of visibility. For views beyond 0.5 miles, for example Wickford Historic District, Wickford Harbor/Wickford Village State Scenic Area, and Narragansett Bay, visibility, considering distance, vegetation screening, viewer perspective, etc., is anticipated to be the top 10-feet of the overhead transmission line structures which are the tallest structure at approximately 80-feet (EDR 2021). Further discussion regarding potential impacts to viewsheds associated with historic or cultural viewsheds can be found in Section 3.10. Nevertheless, the OnSS and ICF would not be out of scale or character with the existing development present in the vicinity, which ranges from transit rail and four-lane roadway to residential to heavy industrial within 0.5 mile of the OnSS and ICF location. For this reason, the OnSS and ICF would result in long-term **negligible** adverse impacts to the viewer's and associated LCA. Impacts during decommissioning would be similar to the impacts during construction and installation.

#### 3.20.2.3.3 Cumulative Impacts

#### Offshore Activities and Facilities

Light: Construction-related activities would add lighting used by offshore vessels and construction areas to the No Action Alternative. Construction of up to 100 WTGs and two OSSs would also add warning lighting to the No Action Alternative, which would be visible from several KOPs, character areas, and SDAs. New lighting from the Proposed Action would increase in-water structures with lighting impacts from past, present, and reasonably foreseeable future projects (assumed to be 893 structures) for a combined total of 995 lighted structures within the GAA, a 11% increase in lighting compared to the No Action Alternative (see Table E4-1). Nighttime vessel and construction area lighting during construction of the Proposed Action would be limited in duration and cease when construction is complete. Atmospheric and environmental conditions would influence visibility and perceivability from KOPs, character areas, and SDAs. Cumulatively, when combined with other past, present, and reasonably foreseeable future projects, the Proposed Action would result in long-term **negligible** to **major** adverse impacts to nighttime viewers and the existing night sky environment.

Presence of structures: Construction activities would add up to 100 additional WTGs and two OSSs to the No Action Alternative. As a result, approximately 90% of the total potential WTGs and OSSs in the GAA (995) would be associated with other future offshore wind development projects beyond the Proposed Action and at distances from KOPs, character areas, and SDAs where atmospheric conditions and the curvature of the Earth influence visibility. The position of the Proposed Action within the Lease Area, in relation to the other offshore wind development projects, shields or obscures visibility of those projects from KOPs in the northwestern to northeastern portions of the GAA (e.g., RI01, AIO5, and CI01). KOPs in these locations would have views of the Proposed Action as it is the closest project in relation to other projects. KOPs located along the western and eastern portions of the GAA (e.g., BI09, MV03, and NI10) would have increased visibility and therefore increased impacts related to future offshore wind projects in addition to the Proposed Action (see Table G-VIS9). When combined with other past, present, and reasonably foreseeable projects, the Proposed Action would result in long-term **negligible** (e.g., KOP MM 04) to **major** adverse cumulative impacts to KOPs, character areas, and SDAs. Adverse impacts would be removed at Project decommissioning.

### Onshore Activities and Facilities

<u>Light:</u> Onshore construction and O&M would add an O&M facility, OnSS, and ICF with nighttime security lighting to the No Action Alternative. These onshore structures and nighttime lighting sources would occur in areas of existing development or where similar infrastructure and development exists; would use or replace existing structures (O&M facility); and when considered cumulatively with past, present, and reasonably foreseeable activities would result in long-term **negligible** adverse impacts to the viewer's nighttime visual experience and inherent nighttime landscape character.

<u>Presence of structures:</u> Onshore construction and installation would add an ICF, and OnSS to the No Action Alternative. The O&M facility would use existing structures. The Proposed Action does not include any updates to ports. Any potential future port upgrades required to service the offshore wind industry would potentially result in similar **negligible** adverse visual impacts to KOPs, character areas, and SDAs. The Proposed Action when combined with past, present, and reasonably foreseeable activities would result in long-term **negligible** adverse cumulative impacts to KOPs, character areas, and SDAs.

### 3.20.2.3.4 Conclusions

Project construction and installation, O&M, and decommissioning would introduce visible vessels, structures, and warning lighting to the GAA. BOEM anticipates the impacts resulting from the Proposed Action alone would range from short term to long term **negligible** to **major** adverse. Of the 60 impact determinations associated with KOPs, character areas, and SDAs, 21 major, 21 moderate, 11 minor, and seven negligible adverse impacts were determined for the Proposed Action (see Appendix G); therefore, BOEM anticipates the overall impact on KOPs, character areas, and SDAs from the Proposed Action to be **long term moderate to major adverse because** the overall effect would be substantial to dominant based on the largest number of impact determinations for the for the life of the Project, but the resource would be expected to recover completely after decommissioning. BOEM anticipates that the overall impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would be **negligible** to **major** adverse to KOPs, character areas, and SDAs. Decommissioning after a project's life of up to 35 years would remove the cumulative visual impacts of the Project.

## 3.20.2.4 Alternatives C, D, E, and F

Table 3.20-1 provides a summary of IPF findings for these alternatives.

#### 3.20.2.4.1 Conclusions

Project construction and installation, O&M, and decommissioning would introduce visible vessels, structures, and warning lighting to the GAA. Analysis findings that identify an action alternative associated with Alternatives C, D, E, and F that has the greatest potential for reduced visual impacts (least impactful) as a result of the removal of turbines in relation to KOPs or character areas, have been carried forward in Table 3.20-1 rather than describe impacts for all action alternatives where differences are negligible. Of the 12 action alternatives (C, D, E, and F); four alternatives (C1, D1+D2+D3, E1, and F) were determined to have a lesser degree of visual impacts to KOPs and SCAs than the remaining eight action alternatives and are described below.

Alternatives C1 and C2: Because of WTG placement, Alternative C2 would result in slightly lesser degree of impacts than Alternative C1. Alternative C2 would result in short-term to long-term **negligible** to **major** adverse impacts to KOPs, with 10 of the 17 selected KOPs having major adverse impacts, four KOPs having moderate adverse impacts, and three KOPs having minor to negligible adverse impacts. Impacts to SDAs would range from **negligible** to **major** adverse, with approximately 29,967 acres of visibility of Alternative C2 (14.4%) of the approximately 195,701 acres of SDAs. Impacts to the OCA would be **major** adverse, similar to other action alternatives, with approximately 96% of the OCA having visibility of Alternative C2. Impacts to SCAs and LCAs would range from **minor** to **moderate** adverse based on the sensitivity and degree of magnitude in relation to the character area; overall, Alternative C2 would be visible to approximately 34.7 square miles (2.3%) of the combined SCAs and LCAs within the GAA. Due to the similarity in placement of WTGs, Alternatives C1 and C2 would result in similar impacts, and both alternatives would result in fewer impacts than the Proposed Action. Of the 40 impact determinations associated with KOPs, character areas, and SDAs, 14 major, 13 moderate, eight minor, and five negligible adverse impacts were determined for Alternative C2 (Tables G-VIS3 and G-VIS4c).

Alternative D alternatives: Of the seven Alternative D alternatives, Alternative D1+D2+D3 would result in the least number of adverse impacts because of the combination of removed turbines as compared to the maximum-case scenario for the Proposed Action. Alternative D1+D2+D3 would result in short-term to long-term **negligible** to **major** adverse impacts to KOPs within the GAA, with 12 of the 37 selected KOPs having major adverse impacts, 14 KOPs having moderate adverse impacts, and 11 KOPs having minor to negligible adverse impacts. Impacts to SDAs would range from **negligible** to **major** adverse, with approximately 28,840 acres of visibility of Alternative D1+D2+D3 (13.9%) of the approximately 208,009 acres of SDAs. Impacts to the OCA would be **major** adverse, similar to other action alternatives, with approximately 96% of the OCA having visibility of the Project. Impacts to SCAs and LCAs would range from **minor** to **moderate** adverse, similar to the Proposed Action, based on the sensitivity and degree of magnitude in relation to the character area. Overall, approximately 31.1 square miles (2.1%) of the combined SCAs and LCAs would have visibility of Alternative D1+D2+D3 within the GAA. Of the 60 impact determinations associated with KOPs, character areas, and SDAs, 15 major, 24 moderate, 12 minor and 9 negligible impacts were determined for Alternative D1+D2+D3 (Tables G-VIS5a and G-VIS6c).

Alternative E1 and E2: Because of the placement of WTGs, Alternative E1 would result in slightly fewer impacts than Alternative E2. Alternative E1 would result in short-term to long-term **negligible** to **major** adverse impacts to KOPs within the GAA, with four of the 21 selected KOPs having major adverse impacts, 12 KOPs having moderate adverse impacts, and five KOPs having minor to negligible adverse impacts. The removal of WTGs from the central and northern portions of the Lease Area would increase the distance between KOPs and WTGs in those portions of the Lease Area. Views of WTGs from KOP MV07 (Aquinnah Overlook), for example, would be similar to the Proposed Action at the far-left field of view and to the right of Nomans Land Island where WTGs have not been removed and are the nearest WTGs to KOP MV07 (approximately 13 nm as indicated in Appendix G Table G-VIS7 as the worst case scenario). Within the field of view continuing to pan from left to right where WTGs have been removed, WTGs would increase in distance from the KOP and range from approximately 14 nm (center left) to approximately 18 nm (far right) (Figure 3.20-2).

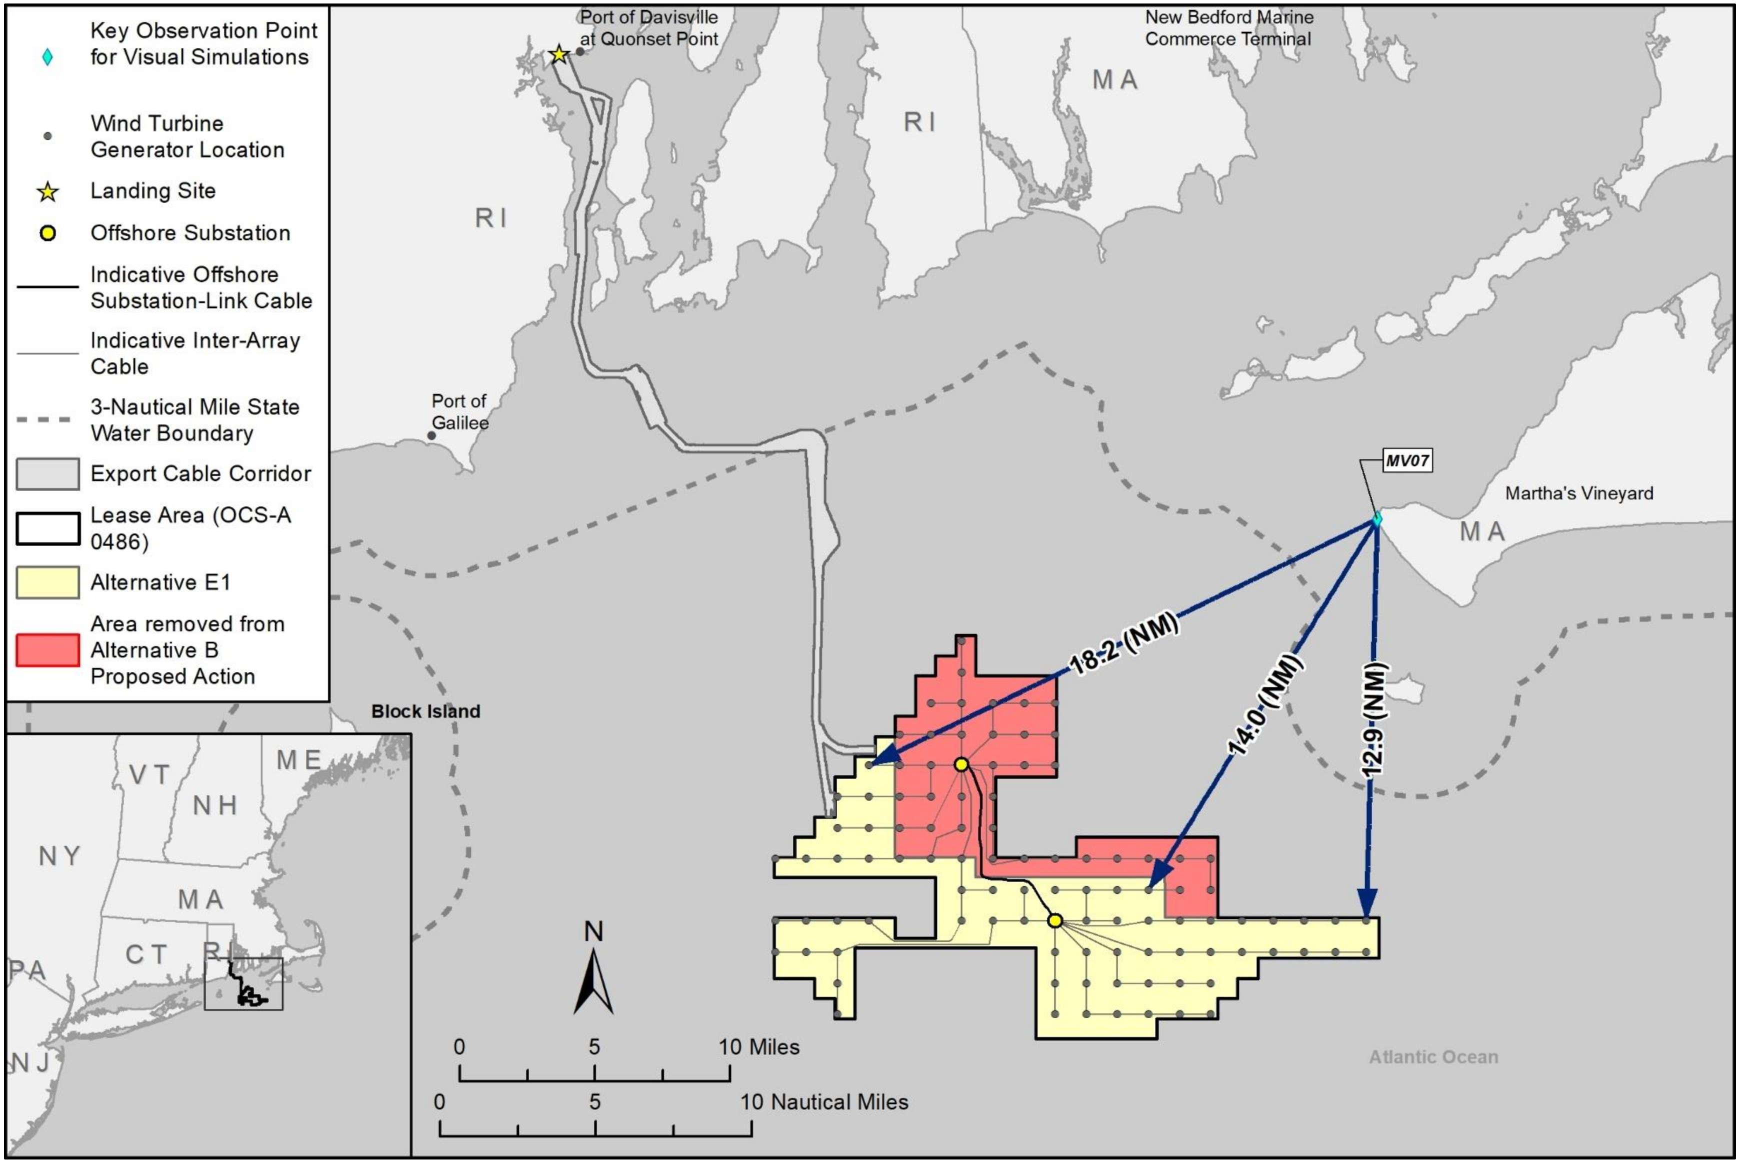

**Figure 3.20-2. Alternative E1 - nearest wind turbine generator to KOP MV07.**

Impacts to SDAs would range from **negligible** to **major** adverse. with approximately 29,085 acres of visibility of Alternative E1 (14.0%) of the approximately 208,009 acres of SDAs. Impacts to the OCA would be **major** adverse, similar to the Proposed Action, with approximately 96% of the OCA having visibility of the alternative. Impacts to SCAs and LCAs would range from **minor** to **moderate** adverse based on the sensitivity and degree of magnitude in relation to the character area. Overall, approximately 32.7 square miles (2.2%) of the combined SCAs and LCAs would have visibility of Alternative E1 within the GAA. Of the 44 impact determinations associated with KOPs, character areas, and SDAs, eight major, 21 moderate, seven minor, and eight negligible adverse impacts were determined for Alternative E1 (see Tables G-VIS7 and G-VIS8c).

Alternative E2 would result in short-term to long-term **negligible** to **major** adverse impacts to KOPs within the GAA; with one of the 16 selected KOPs having major adverse impacts, six KOPs having moderate adverse impacts, and nine KOPs having minor to negligible adverse impacts. The removal of WTGs from the northern and northwest portions of the Lease Area associated with Alternative E2 would increase the distance between the Rhode Island and Block Island KOPs and the viewer’s field of view. The size and scale of impact to views of WTGs as seen from KOP MV07 (Aquinnah Overlook) would be similar to the Proposed Action; however, the removal of WTGs at the far-right proximity of the Lease Area (approximately 11.9 nm) would reduce the western encroachment into the sunset view; therefore, the overall field of view of WTGs would be reduced as compared to the Proposed Action (Figure 3.20-3).

Impacts to SDAs would range from **negligible** to **major** adverse, with approximately 29,385 acres of visibility of Alternative E2 (14.1%) of the approximately 208,009 acres of SDAs. Impacts to the OCA would be **major** adverse, similar to the Proposed Action, with approximately 96% of the OCA having visibility of the alternative. Impacts to SCAs and LCAs would range from **minor** to **moderate** adverse based on the sensitivity and degree of magnitude in relation to the character area. Overall, approximately 33.5 square miles (2.3%) of the combined SCAs and LCAs would have visibility of Alternative E2 within the GAA. Of the 39 impact determinations associated with KOPs, character areas, and SDAs, five major, 15 moderate, seven minor, and 12 negligible adverse impacts were determined for Alternative E2 (see Tables G-VIS7 and G-VIS8c).

Alternatives E1 and E2 would not have as great of a reduced visual impact within the GAA. Because of the specific nature and development of Alternatives E1 and E2 related to reducing visual impacts to specific KOPs along the northeastern portion of the Lease Area associated with Martha’s Vineyard (e.g., MV08, Aquinnah Overlook and MV12, Peaked Hill), KOPs in this geographic area would have greater reduced visual impacts as compared to other action alternatives. Additionally, some KOPs that are at a greater distance (e.g., AI05 [Sachuest Point National Wildlife Refuge]) would also have reduced visual impacts based on orientation to the Lease Area.

Further information related to impacts to individual KOPs, character areas, and SDAs associated with Alternatives C, D, and E is included in Appendix G.

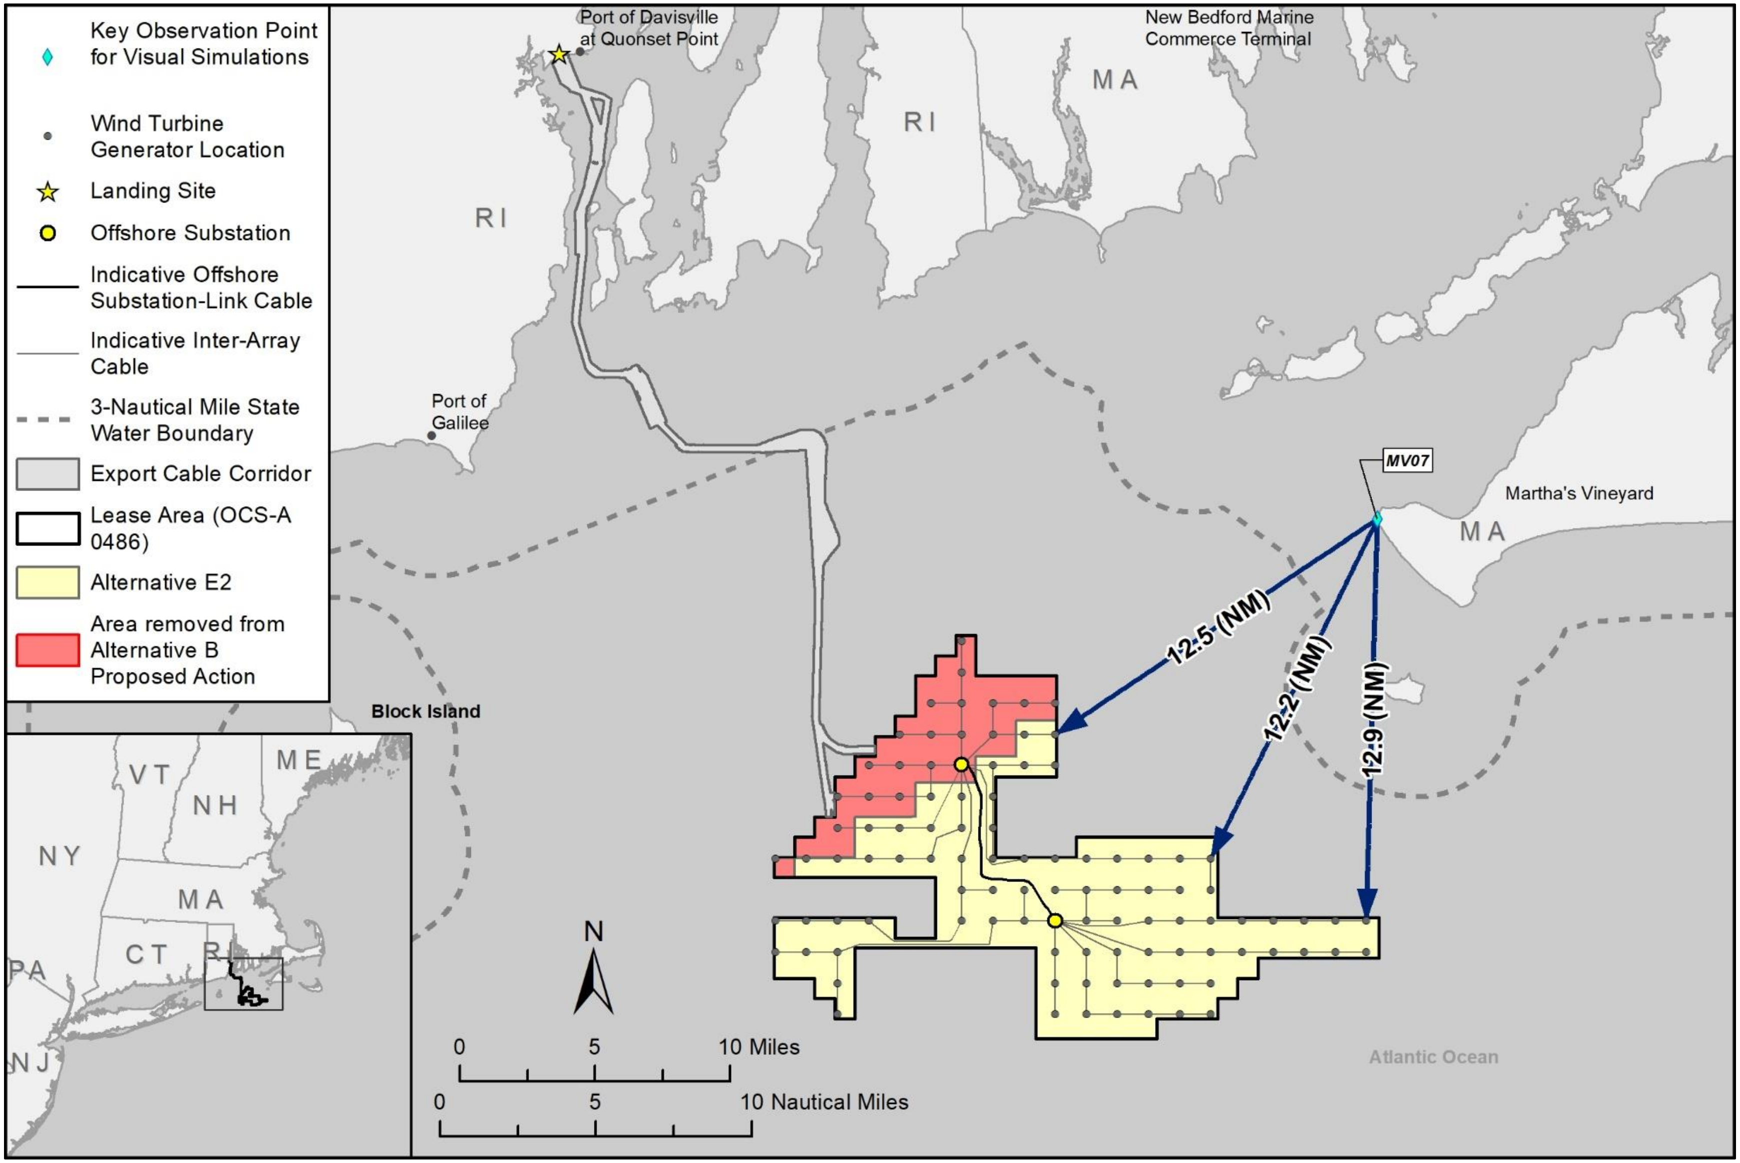

**Figure 3.20-3. Alternative E2 - nearest wind turbine generator to KOP MV07.**

Alternative F would reduce the number of WTGs installed in the Lease Area as compared to the maximum-case scenario for the Proposed Action or any action alternative that it is combined with. The potential reduction of impacts would depend on viewer distance and be focused primarily on locations in closest proximity to the area of reduced WTGs. A reduction in WTGs installed would be expected to result in long-term **negligible** to **major** adverse impacts to KOPs, character areas, and SDAs. However, the application of Alternative F cannot be fully evaluated until the specific WTGs to be removed are identified.

In the context of other reasonably foreseeable environmental trends and planned actions, BOEM anticipates that the overall impacts associated with Alternatives C2, D1+D2+D3, E1, and F or any other alternative option when combined with past, present, and reasonably foreseeable activities would be **negligible** to **major** adverse. This impact determination is due to the proximity of the Project within the Lease Area and in relation to KOPs, character areas, and SDAs. Additionally, impacts would be variable based on the final alternative selected and range from 1,011 to 1,048 structures (WTGs and OSSs). Decommissioning would remove the cumulative visual impacts of the Project.

### 3.20.2.5 Alternative G: Impacts of the Preferred Alternative on Visual Resources

Table 3.20-1 provides a summary of IPF findings for this alternative.

#### 3.20.2.5.1 Conclusions

Because of the placement of WTGs in relation to KOPs, Alternatives G2 and G3 would have the greatest reduced visual impact as compared to the Proposed Action. Information related to overall impact determinations for Alternatives G and G1 is included in Appendix G. Alternative G2 would result in fewer impacts than Alternative G3. Alternative G2 would result in short-term to long-term **negligible** to **major** adverse impacts to KOPs within the GAA, with one of the 19 selected KOPs having major adverse impacts, 10 KOPs having moderate adverse impacts, and four KOPs having minor to negligible adverse impacts. Comparatively, Alternative G3 would have 10 of the 22 selected KOPs with major adverse impacts, seven KOPs with moderate adverse impacts, one KOP with minor impacts, and four KOPs with negligible adverse impacts.

Impacts to SDAs would range from negligible to major adverse under Alternative G, with Alternative G2 having the greatest reduced visibility with approximately 30,499 acres of visibility (14.6%) of the approximately 208,009 acres of SDAs as compared to 30,477 acres of visibility (14.7%) associated with Alternative G3. Impacts to the OCA would be major adverse, similar to other action alternatives, with Alternative G visible to approximately 96% of the OCA.

Impacts to SCAs and LCAs would range from **minor** to **moderate** adverse based on the sensitivity and degree of magnitude in relation to the character area; overall, Alternative G3 would be the least visible to approximately 33.4 square miles (2.2%) of the combined SCAs and LCAs within the GAA as compared 33.5 square miles (2.3%) associated with Alternative G2. Of the 42 impact determinations associated with KOPs, character areas, and SDAs, six **major**, 19 **moderate**, eight **minor**, and nine **negligible** adverse impacts were determined for Alternative G2 as compared to 10 **major**, seven **moderate**, one **minor**, and four **negligible** adverse impacts associated with Alternative G3 (see Tables G-VIS9 to G-VIS10c).

Further information related to impacts to individual KOPs, character areas, and SDAs associated with Alternative G is included in Appendix G.

In the context of other reasonably foreseeable environmental trends and planned actions, BOEM anticipates that the overall impacts associated with Alternatives G when combined with past, present, and reasonably foreseeable activities would be negligible to major adverse. This impact determination is due to the proximity of the Project within the Lease Area and in relation to KOPs, character areas, and SDAs. Additionally, impacts would be variable based on the final alternative selected and range from 964 to 978 structures (WTGs and OSSs). Decommissioning would remove the cumulative visual impacts of the Project.

#### 3.20.2.6 Mitigation

No mitigation measures resulting from agency consultations for visual resources are identified in Appendix F, Table F-2. Additional mitigation measures identified by BOEM and cooperating agencies are listed in Appendix F, Table F-3, and addressed in Table 3.20-5.

**Table 3.20-5. Additional Mitigation and Monitoring Measures for Visual Resources (Appendix F, Table F-3)**

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
| --- | --- | --- |
| Visual impacts monitoring plan | Monitoring visual effects during construction and operations in the daytime and nighttime | This measure would not modify the impact determination for visual resources but would provide the information necessary to ensure that these effects do not exceed the levels analyzed herein. |

##### 3.20.2.6.1 Measures Incorporated into the Preferred Alternative

Mitigation measures resulting from consultations, authorizations, and permits listed in Table 3.20-5 and in Appendix F, Table F-2, are incorporated into Alternative G (Preferred Alternative). The visual impacts monitoring plan, if adopted, would further define how the effectiveness and enforcement of EPMs would be ensured. This mitigation measure would improve accountability for compliance with EPMs by requiring the submittal of plans for approval by the enforcing agency(ies) and by defining reporting requirements. Because this measure ensures the effectiveness of and compliance with EPMs, as part of a formalized monitoring plan, that is already analyzed as part of the Proposed Action, implementation of this measure would not further reduce the impact level of the Proposed Action from what is described in Section 3.20.2.3.

## 3.21 Water Quality

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to water quality from implementation of the Proposed Action and other considered alternatives.

## 3.22 Wetlands and Non-tidal Waters

The reader is referred to Appendix E2 Assessment of Resources with Minor (or Less) Impact Determinations for a discussion of current conditions and potential impacts to wetlands and non-tidal waters from implementation of the Proposed Action and other considered alternatives.

# APPENDIX A

## Required Environmental Permits and Consultations

# Contents

# Tables

*This page intentionally left blank.*

# Introduction

This appendix discusses required permitting and public, agency, and tribal involvement in the preparation of the Revolution Wind Farm (RWF) and Revolution Wind Export Cable (RWEC) Project (the Project) environmental impact statement (EIS). This involvement included formal consultations, cooperating agency exchanges, and a public scoping comment period.

Authorizations and permits are listed in Table A-1, and cooperating or participating federal agencies are described below. The Bureau of Ocean Energy Management (BOEM) has completed the following interagency milestones to date for the Project:

- Finalize purpose and need: April 19, 2021
- Concurrence on permitting timetable: April 19, 2021
- Issuance of notice of intent (NOI) to prepare an EIS: April 30, 2021
- Issuance of notice of correction: June 4, 2021
- Complete public scoping period: June 11, 2021
- Finalize Draft EIS alternatives: April 19, 2022

# Other Federal and State Review

In addition to the BOEM-led National Environmental Policy Act (NEPA) process at the federal level, the Project is also being reviewed through a robust state permitting process, including the Rhode Island Department of Environmental Management; the Rhode Island Coastal Resources Management Council (RI CRMC); the Massachusetts Office of Coastal Zone Management (MA CZM); and various state historic preservation offices (SHPOs), including the Rhode Island Historic Preservation & Heritage Commission, the Massachusetts Historical Commission, the Connecticut State Historic Preservation Office, the New York State Division of Historic Preservation, and the Massachusetts Board of Underwater Archaeological Resources through Section 106 of the National Historic Preservation Act (NHPA). BOEM is also coordinating with federally and non-federally recognized tribal nations, local governments, and non-governmental organizations.

Table A-1 provides a discussion of other federal and state reviews required, including legal authority, jurisdiction of the agency, and the regulatory process involved.

**Table A-1. Cooperating Federal and State Agencies, Required Environmental Permits, and Consultations for the Project**

| Agency/Regulatory Authority | Cooperating Agency Status | Permit/Approval/Consultations | Status |
|---|---|---|---|
| **Federal** | | | |
| Advisory Council on Historic Preservation | Participating agency | None | Not applicable |
| BOEM | Lead federal agency | Construction and operations plan (COP) approval | Original COP filed with BOEM on October 30, 2020; COP updates provided on April 29, 2021; December 15, 2021; July 21, 2022; and March 1, 2023 |
| Bureau of Safety and Environmental Enforcement | Cooperating agency | Facility design report/Fabrication and installation report, oil spill response plan, safety management system, and decommissioning for project | Planned |
| National Park Service | Participating agency | None | Not applicable |
| U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service | Cooperating agency | Letter of authorization (LOA) for incidental take regulations (ITRs) Essential fish habitat consultation<br>Endangered Species Act (ESA) consultation | Planned |
| U.S. Department of Defense, U.S. Army Corps of Engineers | Cooperating agency | Clean Water Act Section 404/Rivers and Harbors Act of 1899 Section 10<br>Individual Permit | Planned |
| U.S. Department of Defense | Participating agency | None | Not applicable |
| U.S. Department of Transportation, Federal Aviation Administration | Participating agency | Obstruction evaluation/airport airspace analysis | Planned |
| U.S. Department of Homeland Security, U.S. Coast Guard | Cooperating agency | Private Aids to Navigation Permit | Planned |

| Agency/Regulatory Authority | Cooperating Agency Status | Permit/Approval/Consultations | Status |
|---|---|---|---|
| U.S. Department of the Navy | Participating agency | None | Not applicable |
| U.S. Environmental Protection Agency | Cooperating agency | Outer Continental Shelf Air Permit | Planned |
| U.S. Fish and Wildlife Service | Participating agency | ESA consultation | Planned |
| **State (portions of the Project within state jurisdiction)*** | | | |
| State of Rhode Island Coastal Resources Management Council | Cooperating agency | Coastal Zone Management Act (CZMA) Consistency Certification<br>Category B Assent/Submerged lands license<br>Permit to Alter Freshwater Wetlands in the Vicinity of the Coast<br>Application for Marine Dredging and Associated Activities | Filed on June 7, 2021; concurrence issued on May 12, 2023<br>Filed on July 1, 2021; completed Q1 2023<br>Filed on July 1, 2021<br>Filed on July 1, 2021 |
| State of Rhode Island Department of Environmental Management | Cooperating agency | Section 401 and State Water Quality Certification/Rhode Island Pollutant Discharge Elimination System Construction General Permit (filed concurrently)<br>Application for Marine Dredging and Associated Activities (see above) | Filed on August 3, 2021 |
| MA CZM | Cooperating agency | CZMA Consistency Certification | Filed on June 7, 2021; concurrence issued on May 10, 2023 |
| Connecticut State Historic Preservation Office, Connecticut Department of Economic and Community Development | Not applicable | NHPA Section 106 consultation | Not applicable |
| Rhode Island Historical Preservation & Heritage Commission | Not applicable | NHPA Section 106 consultation | Not applicable |

| Agency/Regulatory Authority | Cooperating Agency Status | Permit/Approval/Consultations | Status |
|---|---|---|---|
| New York State Division for Historic Preservation | Not applicable | NHPA Section 106 consultation | Not applicable |
| Massachusetts Historical Commission | Not applicable | NHPA Section 106 consultation | Not applicable |

* State agencies may be cooperating agencies under NEPA.

## Cooperating Agencies

As part of the NEPA process, BOEM invited other federal agencies and state, tribal, and local governments to consider becoming cooperating agencies in the preparation of the EIS. According to Council on Environmental Quality (CEQ) guidelines, qualified agencies and governments are those with "jurisdiction by law" or "special expertise" (40 Code of Federal Regulations [CFR] 1501.8). BOEM asked potential cooperating agencies to consider their authority and capacity to assume the responsibilities of a cooperating agency and to be aware that an agency's role in the environmental analysis neither enlarges nor diminishes the final decision-making authority of any other agency involved in the NEPA process. BOEM also provided potential cooperating agencies participating in the FAST-41 process with a written summary of expectations for cooperating agencies, including time schedules and critical action dates, milestones, responsibilities, scope, detail of cooperating agencies' contributions, and availability of pre-decisional information.

Cooperating agency status is provided in Table A-1. More specific details regarding federal agency roles and expertise are described below.

### National Marine Fisheries Service

The National Marine Fisheries Service (NMFS) is serving as a cooperating agency pursuant to 40 CFR 1501.8 because the scope of the Proposed Action and alternatives involves activities that could affect marine resources under its jurisdiction by law and special expertise. As applicable, permits and authorizations are issued pursuant to the Marine Mammal Protection Act, as amended (MMPA) (16 United States Code [USC] 1361 et seq.); the regulations governing the taking and importing of marine mammals (50 CFR 216); the Endangered Species Act (ESA) (16 USC 1531 et seq.); and the regulations governing the taking, importing, and exporting of threatened and endangered species (50 CFR 222–226). In accordance with 50 CFR 402, NMFS also serves as the consulting agency under Section 7 of the ESA for federal agencies proposing actions that may affect marine resources listed as threatened or endangered and critical habitat. NMFS has additional responsibilities to conserve and manage fishery resources of the United States, which include the authority to engage in consultations with other federal agencies pursuant to the Magnuson-Stevens Fishery Conservation and Management Act (MSA) and 50 CFR 600 when proposed actions may adversely affect essential fish habitat (EFH). The MMPA is the only authorization for NMFS that requires NEPA compliance. NMFS intends to adopt BOEM's Final EIS if, after independent review and analysis, NMFS determines the Final EIS to be sufficient to support the authorization.

NMFS has multiple roles in the NEPA process and EIS for this major federal action. First, NMFS has a responsibility to serve as a cooperating agency based on its technical expertise and legal jurisdiction over multiple trust resources. NMFS's role is to provide expert advice regarding the action's impact with respect to EFHs, as defined in the MSA, listed threatened and endangered species and designated critical habitat listed under the ESA, marine mammals protected by the MMPA, and commercial and recreational fisheries managed under the MSA.

Second, NMFS intends to adopt the EIS in support of its MMPA authorization decision after reviewing it and determining it to be sufficient. NMFS is required to review applications for incidental take under the MMPA, as amended (16 USC 1361 et seq.) and issue an Incidental Take Authorization (ITA) in the form of a Letter of Authorization (LOA) for Incidental Take Regulations (ITRs) if appropriate. Revolution

Wind, LLC (Revolution Wind) has submitted an application to NMFS for an ITR in conjunction with the construction and operations plan (COP) for *take*, as defined by the MMPA, of marine mammals incidental to Project construction and associated activities. The decision to issue an ITR under the MMPA is considered a major federal action requiring NEPA review. Therefore, NMFS has an independent responsibility to comply with NEPA. Consistent with the regulations published by the CEQ (40 CFR 1501.7(g)), NMFS intends to rely on the information and analyses in BOEM's EIS to fulfill its NEPA obligations for ITA issuance, if applicable. NMFS intends to adopt the final EIS for this purpose.

The following list provides a timeline for NMFS-related Project documentation (BOEM 2023a, 2023b, 2023c, 2023d).

- Draft ESA biological assessment (BA) and EFH submitted to NMFS on April 25, 2022.
- NMFS provided comments on June 22, 2022.
- Revised ESA BA and EFH submitted on August 29, 2022.
- NMFS provided comments and requested changes on EFH on September 22, 2022.
- Revised ESA BA was submitted on November 1, 2022.
- NMFS deemed insufficient on November 11, 2022.
- BOEM submitted revised BA addendum on January 31, 2023.
- NMFS requested additional 60 calendar days to complete ESA and EFH consultations.
- BOEM submitted revised EFH consultation on February 7, 2023.
- NMFS determined EFH assessment complete on March 23, 2023.
- NMFS determined ESA consultation package complete on March 31, 2023.
- EFH consultation concludes on June 16, 2023.
- ESA consultation concludes on July 21, 2023.

NMFS published proposed ITA under MMPA on December 16, 2022.

NMFS proposed ITA under MMPA public comment period extended to February 7, 2023.

### Bureau of Safety and Environmental Enforcement

The Bureau of Safety and Environmental Enforcement (BSEE) is serving as a cooperating agency pursuant to 40 CFR 1501.8 because the scope of the Proposed Action and alternatives involves activities that could affect marine resources under its jurisdiction by law and special expertise. BSEE's roles and responsibilities are outlined in 30 CFR 285.633 (BSEE and BOEM 2023).

### U.S. Coast Guard

The U.S. Coast Guard (USCG) is serving as a cooperating agency pursuant to 40 CFR 1501.8 because the scope of the Proposed Action and alternatives involves activities that could affect navigation and safety issues that fall under its jurisdiction by law and special expertise. Upon lessee application, the USCG will issue a Private Aids to Navigation (PATON) permit for the marking and lighting of the wind turbine generators (WTGs), offshore substations (OSSs), and measurement buoys to alert mariners to potential hazards to navigation. A request for a Local Notice to Mariners (LNMs) publication will also be submitted to the USCG prior to vessel mobilization for construction activities to enable the USCG to issue the LNM.

### U.S. Environmental Protection Agency

The U.S. Environmental Protection Agency (EPA) is serving as a cooperating agency pursuant to 40 CFR 1501.8 because the scope of the Proposed Action and alternatives involves activities that could affect resources under its jurisdiction by law and special expertise. The EPA is responsible for issuing an Outer Continental Shelf (OCS) permit for the Project under the Clean Air Act.

### U.S. Army Corps of Engineers

The U.S. Army Corps of Engineers (USACE) is serving as a cooperating agency pursuant to 40 CFR 1501.8 because the scope of the Proposed Action and alternatives involves activities that could affect resources under its jurisdiction by law and special expertise. As applicable, permits and authorizations are issued pursuant to Section 10 of the Rivers and Harbors Act of 1899 and Section 404 of the Clean Water Act.

Section 10 of the Rivers and Harbors Act, approved on March 3, 1899 (33 USC 403), prohibits the unauthorized obstruction or alteration of any navigable water of the United States. The construction of any structure in or over any navigable water of the United States; the excavating from or depositing of material in such waters; or the accomplishment of any other work affecting the course, location, condition, or capacity of such waters is unlawful unless the work has been recommended by the Chief of Engineers and authorized by the Secretary of the Army. The instrument of authorization is designated a permit. The authority of the Secretary of the Army to prevent obstructions to navigation in navigable waters of the United States was extended to artificial islands, installations, and other devices located on the seafloor, to the seaward limit of the OCS, by Section 4(f) of the Outer Continental Shelf Lands Act of 1953, as amended (43 USC 1333(e)).

Section 404 of the Clean Water Act (33 USC 1344) authorizes the Secretary of the Army, acting through the Chief of Engineers, to issue permits, after notice and opportunity for public hearing, for the discharge of dredged or fill material into the waters of the United States at specified disposal sites (see 33 CFR 323.) The selection and use of disposal sites will be in accordance with guidelines developed by the Administrator of the EPA in conjunction with the Secretary of the Army and published in 40 CFR 230.

The Section 10 activities associated with the Project may consist of the installation of WTGs, the installation of inter-array cables, the installation of export cables, and scour protection associated with the structures. Section 10 activities are regulated by the USACE between the mean high water-mark and the limits of the OCS. The Section 404 fill activities associated with the Project may consist of the placement of scour protection on the export cables, the redeposition of dredged material into the horizontal directional drilling (HDD) pits near the landfall site, the installation of temporary cofferdams, and any other temporary discharges of dredged or fill material associated with the installation of the export cable. Section 404 activities are regulated by the USACE between the high tide line and the 3-nautical-mile mark.

Issuance of Section 10 or Section 404 permits requires NEPA compliance, which will be met via adoption of BOEM’s EIS and issuance of a record of decision (ROD).

### U.S. Fish and Wildlife Service

The U.S. Fish and Wildlife Service (USFWS) is serving as a participating agency for the Project. The USFWS also serves as the consulting agency under Section 7 of the ESA for federal agencies proposing actions that may affect terrestrial resources listed as threatened or endangered, including species of concern. See the ESA section below for a summary of the ESA consultation to date with the USFWS. The USFWS deemed the ESA consultation package complete, and consultation was initiated on November 17, 2022. BOEM submitted additional information to USFWS via an addendum in January 2023 and via a revised addendum in April 2023. Consultation was completed on May 30, 2023.

### National Park Service

The National Park Service (NPS) is serving as a participating agency because there are multiple important NPS resources within the Project vicinity, including the Block Island Southeast Light, Marble House, Ocean Drive Historic District, Bellevue Avenue Historic District, and The Breakers National Historic Landmarks (NHLs). There may also be Land and Water Conservation Fund State and Local Assistance Program sites impacted if more export cable locations are set. However, at this point in time the proposed cable landing at Quonset Business Park in North Kingstown, Rhode Island, is not expected to interact with any NPS units or program lands. Should any potential impacts to NPS units or program lands be identified and an NPS permit is required, the NPS will request a change to cooperating agency status under "jurisdiction by law" pursuant to 40 CFR 1501.8.

## Consultations and Authorizations

The following section provides a summary and status of BOEM consultations and authorizations as part of the Project (ongoing, complete, and the opinion or finding of each consultation). Section 1.4 of the COP provides a discussion of other federal and state consultation processes being led by Revolution Wind (VHB 2023).

### Coastal Zone Management Act

The Coastal Zone Management Act (CZMA) requires that federal actions within and outside the coastal zone that have reasonably foreseeable effects on any coastal use or natural resource of the coastal zone be consistent with the enforceable policies of a state's federally approved coastal management program (CMP). On June 7, 2021, Revolution Wind submitted a federal consistency certification with the MA CZM and the RI CRMC per 15 CFR 930.76. The CZMA federal consistency regulations at 15 CFR 930.60(b) allow for a stay of the required review period, if mutually agreed upon by both the applicant and the state agency.

On July 2, 2021, MA CZM requested additional information deemed necessary to determine consistency with the enforceable policies of its approved CMP and entered into a mutual agreement with Revolution Wind to stay the review for 8 months, beginning on July 7, 2021, with MA CZM's review restarting on March 7, 2022. On March 7, 2022, both parties agreed to a second stay ending May 7, 2022. On August 8, 2022, both parties agreed to a third stay ending on October 12, 2022. On November 21, 2022, both parties agreed to a fourth stay ending February 12, 2023. On February 17, 2023, both parties agreed to a fifth stay ending March 23, 2023. On March 27, 2023, both parties agreed to a sixth stay ending on April 25, 2023.

On May 1, 2023, both parties agreed to a seventh stay ending on May 9, 2023. On May 10, 2023, MA CZM issued a federal consistency determination of concurrence for the RWF Project.

On October 21, 2021, RI CRMC also requested additional information deemed necessary to make a consistency determination. On October 29, 2021, RI CRMC and Revolution Wind entered into an agreement to stay the CRMC's CZMA review until September 17, 2022. On November 17, 2022, RI CRMC and Revolution Wind entered into a second agreement to stay the CRMC's CZMA review until January 20, 2023. On February 8, 2023, RI CRMC and Revolution Wind entered into a third agreement to stay the CRMC's CZMA review until March 14, 2023. On March 3, 2023, RI CRMC and Revolution Wind entered into a fourth agreement to stay the CRMC's CZMA review until April 11, 2023. On March 31, 2023, RI CRMC and Revolution Wind entered into a fifth agreement to stay the CRMC's CZMA review until April 25, 2023. On May 12, 2023, RI CRMC issued a federal consistency determination of concurrence for the RWF Project. The COP provides the necessary data and information under 15 CFR 930.58 (VHB 2023). The states' concurrence is required before BOEM could approve, or approve with conditions, the COP per 30 CFR 585.628(f) and 15 CFR 930.130(1).

### Endangered Species Act

Section 7(a)(2) of the ESA of 1973, as amended (16 USC 1531 et seq.), requires that each federal agency ensure that any action authorized, funded, or carried out by the agency is not likely to jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of critical habitat of those species. When the action of a federal agency could affect a protected species or its critical habitat, that agency is required to consult with either NMFS or the USFWS, depending upon the jurisdiction of the agencies. Pursuant to 50 CFR 402.07, BOEM has accepted designation as the lead federal agency for the purposes of fulfilling interagency consultation under Section 7 of the ESA for listed species under the jurisdiction of NMFS and the USFWS. BOEM is consulting on the proposed activities considered in this EIS with both NMFS and the USFWS for listed species under their respective jurisdictions. Draft biological assessments have been prepared for submission to USFWS and NMFS. USFWS ESA consultations are expected to be completed by March 31, 2023. NMFS ESA consultation is expected to be completed by July 21, 2023.

### Government-to-Government Consultation with Federally Recognized Indian Tribes

Executive Order (EO) 13175 commits federal agencies to engage in government-to-government consultation with tribal nations. A June 29, 2018, memorandum outlines BOEM's current tribal consultation guidance (BOEM 2018). This memorandum states that "consultation is a deliberative process that aims to create effective collaboration and informed Federal decision-making" and is in keeping with the spirit and intent of EO 13175 (BOEM 2018). BOEM implements tribal consultation policies through formal government-to-government consultation, informal dialogue, collaboration, and engagement.

Summaries of BOEM's consultation meetings with tribes are provided in this section and indicate which tribes were in attendance. BOEM invites multiple tribes, unless a one-to-one or follow-up meeting was requested by the tribe.

BOEM conducted government-to-government consultations with the Narragansett Indian Tribe, the Mashantucket (Western) Pequot Tribal Nation, and the Mohegan Tribe of Indians of Connecticut in an overview of planned offshore wind development projects off southern New England in August 2018.

Between January 15 and 17, 2020, BOEM met again with the Mohegan Tribe of Indians of Connecticut, the Mashantucket (Western) Pequot Tribal Nation, and the Narragansett Indian Tribe to discuss multiple BOEM actions in the Rhode Island/Massachusetts Wind Energy Area. Tribal representatives expressed concerns about possible effects on marine mammals, other marine life, and the Nantucket Sound Traditional Cultural Place (TCP). One concern emphasized the importance of open sea views to the east during sunrise, as well as the night sky, whereas others emphasized the long historical association of the tribes with the sea and islands off southern New England and the critical role of fishing and shellfish gathering for tribes. All of the tribes emphasized the importance of understanding the interconnected nature of the human world, the sea, and the living things in both worlds.

In July 2020, BOEM and the BSEE conducted meetings with the Mashantucket (Western) Pequot Tribal Nation, and the Mashpee Wampanoag Tribe. These meetings generally focused on developing mitigation measures for offshore wind project impacts, funding, and best practices. Concerns expressed by representatives from the tribes present included project effects and layout, a desire to redefine the Nantucket Sound TCP boundaries, recommendations for mitigation measures, aboriginal rights and titles, communication with developers, and cumulative effects of the present and future offshore wind projects in the area.

On August 20, 2020, BOEM consulted with the Delaware Tribe of Indians, Mashantucket (Western) Pequot Tribal Nation, Mashpee Wampanoag Tribe, and Wampanoag Tribe of Gay Head (Aquinnah) to discuss the impacts of offshore wind developments on marine mammals. This included an overview of the consultation process and environmental review, the BOEM Environmental Studies Program and process, existing and upcoming studies related to North Atlantic right whales, and the marine mammal analysis and findings noted in the Vineyard Wind 1 supplemental EIS. The meeting concluded with some action items for BOEM, including to provide the above-referenced consulting tribes with additional reports and to research funding options to provide tuition assistance for tribal members interested in participating in the Protected Species Observer training certificate program.

On April 9, 2021, BOEM held a government-to-government consultation meeting with representatives from the Delaware Tribe of Indians, Mashpee Wampanoag Tribe, and Wampanoag Tribe of Gay Head (Aquinnah). Most of the meeting focused on topics and issues applicable to offshore wind development. During the meeting, representatives from the tribes voiced concerns about potential impacts of area offshore wind projects to water quality; marine mammals; culturally and economically significant fisheries and shellfish populations; chemical pollutants; the financial and time burden on tribes of participating in multiple, simultaneous offshore wind project reviews; and preserving natural and cultural resources for future generations, particularly the current and future ability of tribal youth to perform sacred ceremonies and have safe havens for traditional cultural practices in the future. In addition to discussing these concerns, tribal representatives also recommended that BOEM consider creating shared offshore export cable corridors and requested that BOEM consult with federally recognized tribes on all proposed offshore wind projects as one large federal action rather than on a project-by project basis.

In April 2021, BOEM invited by individual letter and email the Mashpee Wampanoag Tribe, Shinnecock Indian Nation, Mashantucket (Western) Pequot Tribal Nation, Wampanoag Tribe of Gay Head (Aquinnah), Mohegan Tribe of Indians of Connecticut, Narragansett Indian Tribe, Delaware Tribe of Indians, and Delaware Nation to join the EIS process as cooperating agencies, to participate in scoping, to meet government-to-government on the Project, and to consult under NHPA Section 106. The invitations and the NOI for the Project notified tribes that BOEM would be using the NEPA substitution process for completing the steps of NHPA Section 106 pursuant to 36 CFR 800.8 (see National Historic Preservation Act section below). BOEM had earlier, in December 2020, notified the consulting tribes of its intent to apply this NEPA substitution process on its future offshore wind development reviews and held a workshop on this process open to tribes in January 2021.

On August 2, 2021, BOEM held a government-to-government meeting with the Wampanoag Tribe of Gay Head (Aquinnah) to discuss visual effects from the South Fork Wind Farm (SFWF) and RWF. The Wampanoag Tribe of Gay Head (Aquinnah) provided comments, and BOEM responses on the agency's tribal consultation practices to date on offshore wind development and the tribe's expressed concerns with the proximity of the SFWF and RWF lease areas and the consideration of alternatives.

On August 13, 2021, BOEM held a government-to-government meeting on RWF and Vineyard Wind South with the Mashpee Wampanoag Tribe, Mashantucket (Western) Pequot Tribal Nation, Wampanoag Tribe of Gay Head (Aquinnah), Delaware Tribe of Indians, and Delaware Nation. The meeting discussed BOEM's decision to use the NEPA substitution process for NHPA Section 106 compliance; cooperating agency status for tribes during NEPA EIS development; tribal land considerations on the OCS; power purchase agreements; BOEM's use of project design envelopes for project reviews; export cables; vessel traffic corridors; HDD at landfall sites; terrestrial archaeology; cumulative visual impacts; traditional cultural practices; potential impact to marine mammals; and project schedules and FAST-41.

On February 3, 2022, BOEM held a government-to-government meeting on RWF with the Mashpee Wampanoag Tribe, Mashantucket (Western) Pequot Tribal Nation, and Wampanoag Tribe of Gay Head (Aquinnah). The meeting discussed tribal land considerations on the OCS, export cables, terrestrial archaeology, marine archaeology, alternatives, cumulative visual impacts, Project schedule, and FAST-41.

On May 2, 2022, BOEM held a government-to-government meeting specifically with the chairwoman, tribal historic preservation office, and council members of the Wampanoag Tribe of Gay Head (Aquinnah). In the meeting, BOEM introduced and discussed the overall renewable energy program and process and summarized details and status of projects off the coast of New England. Topics identified for future discussion included cumulative visual simulations and resource impacts, the transmission process that is part of a lease, decommissioning process and oversight, proposed mitigation plans and agreements, and the tribal capacity building initiatives.

On June 1, 2022, BOEM held a government-to-government meeting with the chairwoman and council members of the Wampanoag Tribe of Gay Head (Aquinnah). This meeting was a follow-up to the May 2 meeting to continue the conversation on various topics and tribal concerns related to the Project as well as to offshore wind development off the New England coast collectively.

On June 2, 2022, the BOEM director met in-person with the Mashpee Wampanoag Tribe to provide the tribal council with an overview of the current state of wind farm permitting off the coast of New England, including Gulf of Maine; to discuss and receive feedback on the Project and regional biological and economic concerns and potential mitigation strategies; to discuss and receive feedback on cumulative visual impacts and simulations; and to discuss and receive feedback on other programmatic topics, including transmission as part of a lease and capacity building initiatives.

On January 24, 2023, and February 3, 2023, BOEM had virtual government-to-government meetings with members of the Mashpee Wampanoag Tribe, Wampanoag Tribe of Gay Head (Aquinnah), and Mashantucket (Western) Pequot Tribal Nation to give an update on the Project, and answer questions.

As part of COP development, Revolution Wind also engaged with tribes, State Historic Preservation Officers, and other stakeholders identified as having potential to inform the design process (see COP Appendix A [BOEM 2023e]).

### Marine Mammal Protection Act

The MMPA was enacted to protect and conserve marine mammals and established a general moratorium on the taking and importation of marine mammals, with certain enumerated exceptions. Unless an exception applies, the act prohibits persons or vessels subject to the jurisdiction of the United States from taking any marine mammal in waters or on lands under the jurisdiction of the United States or on the high seas (16 USC 1372(a)(1), (a)(2)). Section 101(a) of the act provides the prohibitions for the incidental taking of marine mammals. The incidental take of a marine mammal falls under three categories: mortality, serious injury, or harassment (i.e., injury and/or disruption of behavioral patterns). Sections 101(a)(5)(A) and (D) of the act provide the exceptions to the prohibition on take, which give NMFS the authority to authorize the incidental but not intentional take of small numbers of marine mammals, provided certain determinations are made and statutory and regulatory procedures are met. Entities seeking to obtain authorization for the incidental take of marine mammals under NMFS jurisdiction must submit such a request (in the form of an application). ITAs may be issued as either 1) regulations and associated letters of authorization or 2) incidental harassment authorizations when a proposed action will not result in a potential for serious injury and/or mortality or where any such potential can be negated through required mitigation measures. NMFS also promulgated regulations to implement the provisions of the MMPA governing the taking and importing of marine mammals (50 CFR 216) and produced Office of Management and Budget (OMB)–approved application instructions (OMB Number 0648-0151) that prescribe the procedures necessary to apply for permits. All applicants must comply with these regulations and application instructions in addition to the provisions of the MMPA. Once NMFS determines an application is adequate and complete, NMFS has a corresponding duty to determine whether and how to authorize take of marine mammals incidental to the activities described in the application. To authorize the incidental take of marine mammals, NMFS evaluates the best available scientific information to determine whether the take would have a negligible impact on the affected marine mammal species or stocks and an unmitigable impact on their availability for taking for subsistence uses. NMFS must also prescribe the “means of effecting the least practicable adverse impact” on the affected species or stocks and their habitat, and on the availability of those species or stocks for subsistence uses, as well as monitoring and reporting requirements.

NMFS received an application for an ITR from Revolution Wind, which was deemed complete on February 28, 2022, and published in the *Federal Register* on March 21, 2022 (National Oceanic and Atmospheric Administration [NOAA] 2022a). Subsequently, the proposed rule for the taking of marine mammals incidental to implementation of the Revolution Wind Offshore Wind Energy Project was published in the *Federal Register* on December 23, 2022 (NOAA 2022b). As outlined above, NMFS reviews applications to determine whether to issue an authorization for the activities described in the application.

### National Historic Preservation Act

The NHPA (54 USC 306108 et seq.) requires federal agencies to consider the effects of their undertakings on historic properties, to the maximum extent possible plan and act to minimize harm to NHLs, and afford the Advisory Council on Historic Preservation an opportunity to comment. BOEM has determined that approving a COP constitutes an undertaking subject to Section 106 of the NHPA and is implementing the Section 106 process (36 CFR 800). Effects to historic properties from the Project could be direct, indirect, and cumulative. The construction of WTGs, installation of electrical support cables, and development of staging areas are ground- or seafloor-disturbing activities that could directly affect archaeological resources. The presence of WTGs could also introduce visual elements out of character with the historic setting of historic structures or landscapes; in cases where historic setting is a contributing element of historic properties' eligibility for the NRHP, the Project could affect those historic properties, including NHLs. NHLs that may be affected by the undertaking will be addressed according to Section 110(f) of the NHPA pursuant to 36 CFR 800.10. Visual impacts to historic properties, in particular, could be cumulative when the Project adds to the visual impacts of other reasonably foreseeable offshore wind energy developments.

The regulations at 36 CFR 800.8 provide for use of the NEPA process to fulfill a federal agency's NHPA Section 106 review obligations in lieu of the procedures set forth in 36 CFR 800.3–800.6. This process is known as "NEPA substitution for Section 106," and BOEM is using this process and documentation prepared under NEPA to also comply with Section 106. Under NEPA substitution for Section 106 (NEPA Substitution), BOEM is using the public involvement requirements under NEPA to also seek public involvement in its Section 106 review, pursuant to 36 CFR 800.2(d)(3). EIS Appendix J includes BOEM's draft finding of adverse effect, which includes a description and summary of BOEM's consultation to date. BOEM will continue consulting with the Connecticut, Rhode Island, Massachusetts, and New York SHPOs; Advisory Council on Historic Preservation (ACHP); federally recognized tribal nations, and other consulting parties regarding the finding of adverse effect and the resolution of adverse effects. BOEM has and will be conducting Section 106 consultation meeting(s) on the finding of adverse effect and the resolution of adverse effects, and the agency will be requesting the consulting parties to review and comment on the finding of adverse effect and proposed resolution measures. Through NEPA Substitution, resolution of adverse effects will be documented in a memorandum of agreement (MOA) with the consulting parties, concluded prior to the issuance of the ROD.

Under the NEPA process, federally recognized tribes were invited to be cooperating agencies for the Project by BOEM, and officials with the Mashpee Wampanoag Tribe, Mashantucket (Western) Pequot Tribal Nation, and Wampanoag Tribe of Gay Head (Aquinnah) have attended select cooperating agency meetings to date. BOEM received comments from several tribes during June 2021 cooperating agency meetings in the scoping of alternatives and weighed these in the identification of alternatives to consider in detailed EIS analyses. The Mashantucket (Western) Pequot Tribal Nation and the Wampanoag Tribe of Gay Head (Aquinnah) also provided written comments for scoping. Comments received variously from tribes on alternatives included a co-located export cable corridor to be shared with other offshore projects and RWF setbacks and different configurations of WTG layouts to protect the environment (water, wildlife, and other natural and heritage resources) as well as to set back WTGs from land to address visual and cultural impact concerns. A setback option that would restrict/maximize the distance of WTGs from Massachusetts islands was formulated by BOEM in consultation with the Wampanoag Tribe of Gay Head (Aquinnah) and carried forward by BOEM to detailed analyses (i.e., Alternative E). A marine habitat alternative (Alternative C) was also carried forward to detailed analysis based on the comments of many consulting parties, including participating tribes. A draft scoping report was provided for cooperating agency review in June 2021, including to participating tribes.

BOEM fulfilled public involvement requirements for Section 106 of the NHPA through the NEPA public scoping and public meetings process, pursuant to 36 CFR 800.2(d)(3). The scoping summary report (SWCA Environmental Consultants [SWCA] 2022), available on BOEM's Project-specific website, summarizes comments on historic preservation issues. BOEM initiated review under NEPA Substitution on April 2, 2021, with letters sent to identify consulting parties for this undertaking between April 2 and 20, 2021. Letters were then sent between May 11 and 12, 2021, to initiate consultation with those parties previously identified for the undertaking. BOEM posted an additional notification for the public and historic properties owners, and sent letters to local administrators, with an invitation to consult following publication of BOEM's finding of adverse effect under NHPA Section 106 (see EIS Appendix J). BOEM will add additional consulting parties throughout the review process as they are identified. Lists of the consulting parties to date for the Project are provided in BOEM's finding of adverse effect and MOA documents in EIS Appendix J. BOEM held the following consultation meetings with consulting parties:

- An initial consultation meeting with consulting parties on December 17, 2021, to discuss the area of potential effects (APE) and the identification of historic properties within the APE
- A second consultation meeting with consulting parties on April 8, 2022, to discuss the identification of historic properties and potential effects on historic properties
- A third consultation meeting on September 27, 2022, to further discuss adverse effects and their resolution
- A consultation meeting with the Town of Aquinnah on December 5, 2022, focusing on mitigation of adverse effects to historic properties in that town
- A consultation meeting on December 14, 2022, with parties involved with NHLs to review and discuss Project visual effects to NHLs and treatment of adverse effects that would result in harm to NHLs
- A fourth consultation meeting on April 7, 2023, to discuss the identification of the Preferred Alternative, updates to technical reports, and the measures proposed by consulting parties in review of the MOA

Subsequent consultation meetings are anticipated in Q2 2023 and as needed prior to the issuance of the ROD for the purpose of finalizing and executing the MOA.

BOEM's final EIS includes treatment measures for resolving adverse effects to historic properties. The MOA details the final resolution measures to resolve adverse effects, including avoidance, minimization, and mitigation measures.

BOEM has consulted with the ACHP and coordinated with the NPS about a plan on how to handle sensitive information potentially subject to NHPA Section 304. From the beginning of the Section 106 consultation for the Project, BOEM has planned to distribute documents that contain sensitive information to the consulting parties and to post publicly available summaries or redacted versions of Section 106–related documents to BOEM's website. The documents could contain sensitive information on the location and character-defining elements of historic properties that could be subject to NHPA

Section 304—in particular, archaeological sites and sites of religious and cultural significance to tribes. Summaries were posted to BOEM's website for the Project shortly after the Draft EIS was made publicly available. EIS Appendix J contains BOEM's finding of adverse effect and the draft MOA documents, with certain sensitive information redacted. The NEPA scoping, hearings, and review have specifically included presentation of the non-confidential NHPA Section 106 process and information. BOEM notifications to the public on public hearings were posted in local media and newspapers. With respect to the timing of the Draft EIS public review period and the differing dates for technical document review by consulting parties under NHPA Section 106, BOEM believes that it was appropriate to give the consulting parties additional time to review the documents that it distributed to them on August 1, 2022, because supplemental information on NHLs was provided during the review period for the Section 106–related documents and reports on October 1, 2022. With this additional time, the consulting parties had a 90–calendar day review period for the Section 106–related documents from August 1 to October 31, 2022. BOEM elected not to extend the 45-day public comment period on the Draft EIS. Nothing under the NEPA and NHPA Section 106 coordination process under 36 CFR 800.8(c) precludes BOEM from providing consulting parties additional time to review documents specifically related to Section 106 consultation. BOEM has publicly posted the supplemental information on NHLs to the Project website and included the final versions of the finding of effect and MOA documents in the publicly available Final EIS.

In addition to the directives of NEPA and the NHPA, EO 13007 (Indian Sacred Sites) directs federal land management agencies to accommodate access to, and ceremonial use of, Indian sacred sites by Indian religious practitioners and to avoid adversely affecting the physical integrity of such sacred sites. BOEM management actions within the OCS may not directly affect Indian sacred sites; however, BOEM recognizes its undertakings could affect the physical integrity or ceremonial use of Indian sacred sites located on submerged federal lands on the OCS. As stated previously in the Government-to-Government Consultation with Federally Recognized Indian Tribes section, BOEM is also consulting with Indian tribes on these matters in accordance with EO 13175.

### Magnuson-Stevens Fishery Conservation and Management Act

Pursuant to Section 305(b) of the MSA, federal agencies are required to consult with NMFS on any action that may result in adverse effects on EFH. NMFS regulations implementing the EFH provisions of the act can be found at 50 CFR 600. As provided for in 50 CFR 600.920(b), BOEM has accepted designation as the lead agency for the purposes of fulfilling EFH consultation obligations under Section 305(b) of the act. Certain OCS activities authorized by BOEM may result in adverse effects on EFH and therefore require consultation with NMFS. BOEM is developing an EFH assessment concurrent with this EIS. As outlined in the Cooperating Agencies section above, NMFS deemed the EFH assessment from BOEM complete on March 31, 2023. The EFH consultation is expected to conclude on June 21, 2023 (BOEM 2023c, 2023d).

## Public Involvement in Development of the Environmental Impact Statement

This section provides an overview of the development of the EIS, including public scoping, cooperating agency involvement, and distribution of the EIS for public review and comment.

## Scoping

On April 30, 2021, BOEM issued an NOI to prepare an EIS consistent with the regulations implementing NEPA (42 USC 4321 et seq.) to assess the potential impacts of the Proposed Action and alternatives (BOEM 2021a). The NOI initiated a public scoping period from April 30 through June 1, 2021. During this time, input from federal agencies, tribes, state and local governments, and the general public was gathered regarding the potential of significant resources and issues, impact-producing factors, reasonable alternatives (e.g., size, geographic, seasonal, or other restrictions on construction and siting of facilities and activities), and potential mitigation measures to be analyzed in the EIS as well as provide additional information.

A correction to the NOI was issued by BOEM on June 4, 2021, which reopened the public scoping period (BOEM 2021b), allowing for comments to be received by June 11, 2021. The correction addressed and clarified two statements in the NOI regarding the energy capacity of the proposed wind farm and its distance from shore.[1]

BOEM accepted comment submissions on the NOI via the following mechanisms:

- Electronic submissions received via www.regulations.gov on docket number BOEM-2021-0029
- Hard copy comment letters submitted to BOEM via traditional mail
- Emails submitted to BOEM
- Hard copy comment cards and/or letters received during each of the public scoping meetings
- Comments submitted verbally during the listening sessions of each of the three virtual public scoping meetings

BOEM held three virtual public scoping meetings on May 13, May 18, and May 20, 2021. Each virtual public scoping meeting included a presentation, listening session, and a question and answer session, all available on BOEM’s website at https://www.boem.gov/Revolution-Wind-Scoping-Virtual-Meetings.

## Summary of Scoping Comments

BOEM reviewed and considered, as appropriate, all scoping comments in the development of the Draft EIS and used the comments to identify alternatives for analysis. The scoping summary report (SWCA Environmental Consultants 2022) summarizing the 42 submissions received and the methods for analyzing them is available on BOEM’s website at https://www.boem.gov/Revolution-Wind. In addition, all public scoping submissions received can be viewed online at http://www.regulations.gov by typing “BOEM-2021-0029” in the search field. As detailed in the scoping summary report, the resource areas or NEPA topics most referenced in the scoping comments include birds, marine mammals, effects analysis,

[1] Replaced the sentence “The project will deliver 704 MW of power to the New England energy grid.” with “The project would have the capacity to deliver up to 880 MW of power to the New England energy grid, satisfying the current PPA total of 704 MW.” Also replaced the sentence “The wind turbine generators, offshore substations, array cables, and substation interconnector cables would be located on the [Outer Continental Shelf] approximately 17.4 nautical miles (20 statute miles) south of the coast of Rhode Island.” with “The wind turbine generators, offshore substations, array cables, and substation interconnector cables would be located on the Outer Continental Shelf (OCS) approximately 15 nautical miles (18 statute miles) southeast of Point Judith, Rhode Island, approximately 13 nautical miles (15 statute miles) east of Block Island, Rhode Island, approximately 7.5 nautical miles (8.5 statute miles) south of Nomans Land Island National Wildlife Refuge (uninhabited island), and between approximately 10 to 12.5 nautical miles (12 to 14 statute miles) south/southwest of varying points of the Rhode Island and Massachusetts coastlines.”

socioeconomics, commercial fishing, mitigation, wildlife (general), bats, essential fish habitat and finfish, cumulative impacts, and sea turtles.

### Distribution of the Draft Environmental Impact Statement for Review and Comment

On September 2, 2022, BOEM published a notice of availability (NOA) for the Draft EIS. The Draft EIS was made available in electronic format for public viewing at https://www.boem.gov/renewable-energy/state-activities/revolution-wind. Notification was provided, as indicated in Appendix K of the Draft EIS. Hard copies and digital copies of the Draft EIS were delivered to entities as requested. The NOA commenced the 45-day public review and comment period of the Draft EIS through October 17, 2022. BOEM held two virtual public hearings on September 29 and October 11 and three in-person public hearings on October 4–6 and 11, 2022, to solicit feedback and identify issues for consideration in preparing the Final EIS. Throughout the public review and comment period, government agencies, members of the public, and interested stakeholders had the opportunity to provide comments on the Draft EIS in various ways, including the following:

- In hard copy form, delivered by mail, and enclosed in an envelope addressed to Program Manager, Office of Renewable Energy Programs, Bureau of Ocean Energy Management, 45600 Woodland Road, Sterling, Virginia 20166
- Through the regulations.gov online portal by navigating to https://www.regulations.gov/, searching for docket number "BOEM-2022-0045," and submitting a comment
- By attending one of the public hearings on the dates listed in the NOA and providing written or verbal comments

BOEM reviewed and considered all comment submissions in the development of the Final EIS, except those from anonymous sources. BOEM's evaluation of public submissions focused on those comments within the submissions that were identified as substantive. EIS Appendix L describes the public comment processing methodology and includes comment responses. All public comment submissions received on the Draft EIS can be viewed online at https://www.regulations.gov/ by typing "BOEM-2022-0045" in the search field. BOEM received 123 individual comment letters via https://www.regulations.gov/ and 916 individual comments that are summarized and responded to in Appendix L.

### Distribution of the Final Environmental Impact Statement

The EIS is available in electronic form for public viewing at https://www.boem.gov/renewable-energy/state-activities/revolution-wind. Hard copies and digital copies of the Final EIS can be requested by contacting Program Manager, Office of Renewable Energy Programs, Bureau of Ocean Energy Management, 45600 Woodland Road, Sterling, Virginia 20166. Publication of the Final EIS initiates a minimum 30-day mandatory waiting period, during which BOEM is required to pause before issuing a ROD. The ROD will state clearly whether BOEM intends to approve, approve with conditions, or disapprove the COP for construction, O&M, and eventual decommissioning of the Project. Distribution will be provided as indicated in Appendix H of the Final EIS.

# GLOSSARY

| Term | Definition |
|---|---|
| affected environment | Environment as it exists today that could be impacted by the proposed Project |
| ancient submerged landform feature | A landform as it was in ancient times |
| algal blooms | Rapid growth of the population of algae, also known as algae bloom |
| allision | A moving ship running into a stationary ship |
| anthropogenic | Generated by human activity |
| applicant | Revolution Wind, LLC |
| archaeological resource | Historical place, site, building, shipwreck, or other archaeological site on the American landscape |
| automatic identification system | Automatic tracking system used on vessels to monitor ship movements and avoid collision |
| baleen whale | A cetacean with baleens (whalebones) instead of teeth |
| below grade | Below ground level |
| benthic | Related to the bottom of a body of water |
| benthic resources | The seafloor surface, the substrate itself, and the communities of bottom-dwelling organisms that live within these habitats |
| Cetacea | Order of aquatic mammals made up of whales, dolphins, porpoises, and related lifeforms |
| coastal habitat | Coastal areas where flora and fauna live, including salt marshes and aquatic habitats |
| coastal waters | Waters in nearshore areas where bottom depth is less than 98.4 feet |
| coastal zone | The lands and waters starting at 3 nautical miles from the land and ending at the first major land transportation route |
| cofferdam | A watertight enclosure pumped dry to permit construction work below the waterline |
| commercial fisheries | Areas or entities raising and/or catching fish for commercial profit |
| commercial-scale wind energy facility | Wind energy facility usually greater than 1 megawatt that sells the produced electricity |
| criteria pollutant | One of six common air pollutants for which the U.S. Environmental Protection Agency sets National Ambient Air Quality Standards: carbon monoxide, lead, nitrogen dioxide, ozone, particulate matter, or sulfur dioxide |
| critical habitat | Geographic area containing features essential to the conservation of threated or endangered species. This is a specific term and designation within the U.S. Endangered Species Act. |
| cultural resource | Historical districts, objects, places, sites, buildings, shipwrecks, and archeological sites on the American landscape, as well as sites of traditional, religious, or cultural significance to cultural groups, including Native American tribes |

| Term | Definition |
|---|---|
| cumulative impacts | Impacts that could result from the incremental impact of a specific action, such as the proposed Project, when combined with other past, present, or reasonably foreseeable future actions or other projects; can occur from individually minor, but collectively significant actions that take place over time |
| demersal | Living close to the ocean floor |
| design envelope | The range of proposed Project characteristics defined by the applicant and used by the Bureau of Ocean Energy Management (BOEM) for purposes of environmental review and permitting |
| dredging | Removal of sediments and debris from the bottom of lakes, rivers, harbors, and other water bodies |
| duct bank | Underground structure that houses the onshore export cables, which consists of polyvinyl chloride (PVC) pipes encased in concrete |
| ecosystem | Community of interacting living organisms and nonliving components (such as air, water, soil) |
| environmental protection measure (EPM) | Measure proposed in a COP to avoid or minimize potential impacts |
| electromagnetic field | A field of force produced by electrically charged objects and containing both electric and magnetic components |
| endangered species | A species that is in danger of extinction in all or a significant portion of its range |
| Endangered Species Act–listed species | Species listed under the Endangered Species Act |
| ensonified | The process of filling with sound |
| environmental consequences | The potential impacts that the construction, operations, maintenance, and decommissioning of the proposed Project would have on the environment |
| environmental justice communities | Minority and low-income populations affected by the proposed Project |
| essential fish habitat | “Those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity” (50 Code of Federal Regulations 600) |
| export cables | Cables connecting the wind facility to the onshore electrical grid power |
| finfish | Vertebrate and cartilaginous fishery species, not including crustaceans, cephalopods, or other mollusks |
| for-hire commercial fishing | Commercial fishing on a for-hire vessel, i.e. a vessel on which the passengers make a contribution to a person having an interest in the vessel in exchange for carriage |
| for-hire recreational fishing | Fishing from a vessel carrying a passenger for hire who is engaged in recreational fishing |

| Term | Definition |
|---|---|
| foundation | The bases to which the wind turbine generators and offshore substation are installed on the seabed. Five alternative foundation designs were considered and reviewed for the Project (Section 2.2.2.2 of the COP): monopile; piled three-, four-, or six-legged jacket; suction caisson jackets; monopod suction caisson; or gravity-based structure. Monopile is the selected foundation type for the Project. |
| hard-bottom habitat | Benthic habitats comprised of hard-bottom (e.g., cobble, rock, and ledge) substrates |
| historic property | Prehistoric or historic district, site, building, structure, or object that is eligible for or already listed in the National Register of Historic Places. Also includes any artifacts, records, and remains (surface or subsurface) related to and located within such a resource |
| horizontal directional drilling | Trenchless technique for installing underground cables, pipes, and conduits using a surface-launched drilling rig |
| hull | Watertight frame or body of a ship |
| inter-array cables | Cables connecting the wind turbine generators to the offshore substations |
| interconnection facility | Substation connecting the proposed Project to the existing bulk power grid system |
| invertebrate | Animal with no backbone |
| jack-up vessel | Mobile and self-elevating platform with buoyant hull |
| jet plow | Method of submarine cable installation equipment that primarily uses water jets to fluidize soil, temporarily opening a channel to enable the cable to be lowered under its own weight or be pushed to the bottom of the trench via a cable depressor. |
| knot | Unit of speed equaling 1 nautical mile per hour |
| landing site | The shoreline landing site at which the offshore cable transitions to onshore |
| Lease Area | The entire area that Revolution Wind, LLC purchased from BOEM. The RWF must be within the Lease Area. |
| marine mammal | Aquatic vertebrate distinguished by the presence of mammary glands, hair, three middle ear bones, and a neocortex (a region of the brain) |
| marine waters | Waters in offshore areas where bottom depth is more than 98.4 feet |
| mechanical cutter | Method of submarine cable installation equipment that involves a cutting wheel or excavation chain to cut a narrow trench into the seabed allowing the cable to sink under its own weight or be pushed to the bottom of the trench via a cable depressor. |
| mechanical plow | Method of submarine cable installation equipment that involves pulling a plow along the cable route to lay and bury the cable. The plow’s share cuts into the soil, opening a temporary trench which is held open by the side walls of the share, while the cable is lowered to the base of the trench via a depressor. Some plows may use additional jets to fluidize the soil in front of the share. |
| monopile or monopile foundation | A long steel tube driven into the seabed that supports a tower |

| Term | Definition |
|---|---|
| National Ambient Air Quality Standards | Limits on atmospheric concentration of six criteria pollutants that are common in outdoor air and considered harmful to public health and the environment as established by the U.S. Environmental Protection Agency under authority of the Clean Air Act. |
| nautical mile | A unit used to measure sea distances and equivalent to approximately 1.15 miles |
| offshore Revolution Wind Export Cable | Export cables located in state or federal waters |
| offshore substation | The interconnection point between the wind turbine generators and the export cable; the necessary electrical equipment needed to connect the inter-array cables to the offshore export cables |
| onshore transmission cable | Export cables located on land |
| operations and maintenance facilities | Would include offices, control rooms, warehouses, shop space, and pier space |
| outer continental shelf | All submerged land, subsoil, and seabed belonging to the United States but outside of states' jurisdiction |
| pile | A type of foundation akin to a pole |
| pile driving | Installing foundation piles by driving them into the seafloor |
| pinnipeds | Carnivorous, semiaquatic, fin-footed marine mammals, also known as seals |
| plume | Column of fluid moving through another fluid |
| private aids to navigation | Visual references operated and maintained by the U.S. Coast Guard, including radar transponders, lights, sound signals, buoys, and lighthouses, that support safe maritime navigation |
| Project | The siting and development of the Revolution Wind Farm and the Revolution Wind Export Cable |
| protected species | Endangered or threatened species that receive federal protection under the Endangered Species Act of 1973 (as amended) |
| right-of-way | Registered easement on private or government land that allows access by another entity. For purposes of renewable energy development of the Outer Continental Shelf (OCS), BOEM defines a right-of-way grant as an authorization issued by BOEM under 30 CFR 585 Subpart B to use a portion of the OCS for the construction and use of a cable or pipeline for the purpose of gathering, transmitting, distributing, or otherwise transporting electricity or other energy product generated or produced from renewable energy but does not constitute a project easement under Subpart B. The term also means the area covered by the authorization. |
| ruderal | Growing on waste ground or among refuse |
| scour protection | Protection consisting of rock and stone that would be placed around all foundations to stabilize the seabed near the foundations as well as the foundations themselves |
| sessile | Attached directly by the base |

| Term | Definition |
|---|---|
| soft-bottom habitat | Benthic habitats include soft-bottom (i.e., unconsolidated sediments) and hard-bottom (e.g., cobble, rock, and ledge) substrates, as well as biogenic habitat (e.g., eelgrass, mussel beds, and worm tubes) created by structure-forming species |
| Revolution Wind Farm (RWF) | The work area containing all proposed wind turbine generators, offshore substations, and inter-array cables |
| substrate | Earthy material at the bottom of a marine habitat; the natural environment that an organism lives in |
| suspended sediments | Very fine soil particles that remain in suspension in water for a considerable period of time without contact with the bottom. Such material remains in suspension due to the upward components of turbulence and currents, and/or by suspension. |
| threatened species | A species that is likely to become endangered within the foreseeable future |
| tidal energy project | Project related to the conversion of the energy of tides into usable energy, usually electricity |
| transition vault | Underground concrete transition vault that to be constructed at the landing site and inside of which offshore and shore South Fork Export Cable would be spliced together. |
| trawl | A large fishing net dragged by a vessel at the bottom or in the middle of sea or lake water |
| turbidity | A measure of water clarity |
| vibracore | Technology/technique for collecting core samples of underwater sediments and wetland soils |
| viewshed | Area visible from a specific location |
| visual resource | The visible physical features on a landscape, including natural elements such as topography, landforms, water, vegetation, and manmade structures |
| wetland | Land saturated with water; marshes; swamps |
| wind energy | Electricity from naturally occurring wind |
| wind energy area | Areas with significant wind energy potential and defined by BOEM |
| wind turbine generator | Component that puts out electricity in a structure that converts kinetic energy from wind into electricity |

# APPENDIX C

## Incomplete or Unavailable Information

# Contents

*This page intentionally left blank.*

# Introduction

In accordance with Section 1502.21[1] of the Council on Environmental Quality regulations implementing the National Environmental Policy Act (NEPA), when an agency is evaluating reasonably foreseeable significant adverse effects on the human environment in an environmental impact statement (EIS) and there is incomplete or unavailable information, the agency shall make clear that such information is lacking.

Given the substantial geographic and temporal scale of the cumulative impacts analysis for the Revolution Wind Farm (RWF) and Revolution Wind Export Cable Project (Project), some information regarding ongoing activities is unavailable or only available in qualitative or summary form—in particular, for many offshore resources. Concerning reasonably foreseeable construction and operations plans (COPs), specific information is available only for COPs that have been submitted for Bureau of Ocean Energy Management (BOEM) review and are publicly available (see Appendix E of the EIS). Given that information is lacking for other offshore wind activities considered reasonably foreseeable, and several of the COPs submitted are currently under review to determine whether they contain complete and sufficient information for environmental review, a series of assumptions were necessary to conduct the cumulative impacts analysis as outlined in Appendix E3, Table E3-1. Although these assumptions were necessary to allow the analysis to proceed with a reasonable degree of certainty, it is not known whether or to what extent future offshore wind activities will proceed according to these assumptions.

In addition to the uncertainty regarding future activities contemplated in the cumulative analysis, there is also incomplete or unavailable information regarding the likely consequences of various activities on the resources analyzed. When incomplete or unavailable information was identified, BOEM considered whether the information was relevant to the assessment of impacts and essential to a reasoned choice among alternatives. If essential to a reasoned choice among the alternatives, BOEM considered whether it was possible to obtain the information and if the cost of obtaining it was unreasonable. If information could not be obtained within the time frame needed for this analysis or because of exorbitant costs, BOEM applied acceptable scientific methodologies to inform the analysis in light of this incomplete or unavailable information. For example, conclusive information on many impacts of the offshore wind industry may not be available for years and would therefore not be available within the contemplated time frame of this NEPA process. In its place, subject matter experts have used the scientifically credible information available and accepted scientific methodologies for proxy indicators or data to evaluate impacts on the resources while this information is unavailable.

# Incomplete or Unavailable Information Analysis for Resource Areas

## Air Quality

Any action alternative for the Project would lead to air quality impacts that range from **negligible** to **moderate** and **minor** beneficial. Although a quantitative emissions inventory analysis of the region over the next 35 years has not been completed, the EIS does disclose annual emissions that could have been

[1] 40 Code of Federal Regulations 1502.22 in Council on Environmental Quality regulations implementing NEPA prior to September 14, 2020.

avoided by using non–fossil fuel energy sources within the air quality geographic analysis area, as well as the health impacts from those avoided emissions. In addition, the differences among action alternatives with respect to direct emissions due to construction and installation, operations and maintenance (O&M), and decommissioning of the Project would likely be small. For this reason, the analysis provided in the EIS is sufficient to support sound scientific judgements and informed decision making related to the use of onshore and offshore portions of the air quality geographic analysis area. In summary, BOEM did not identify incomplete or unavailable information on air quality that is essential to a reasoned choice among alternatives.

## Bats

Habitat use and distribution vary between season and species, and as a result, there will always be some level of incomplete information on the distribution and habitat use of migratory bats in the offshore portions of the bat geographic analysis area. In addition, because U.S. offshore wind is in its infancy, with three offshore wind projects (Block Island Wind Farm, Virginia Commercial Offshore Wind, and Vineyard Wind Farm) having been or currently being constructed at the time of this analysis, there is some level of uncertainty regarding the potential collision risk to individual bats that may be present within the offshore portions of the geographic analysis area. However, empirical data, including regional bat acoustic studies conducted from coastal, island, vessel, or offshore structure locations and regional telemetry data from recent studies focusing on listed species, were used to assess the likelihood of offshore occurrence, seasonal patterns, and bat species composition.

Information on collision risk to migratory bats is also available from observations collected at land-based U.S. wind facilities, and based on a number of assumptions regarding the applicability to offshore environments, this information was used to analyze and evaluate the potential for collisions associated with the wind turbine generators (WTGs) analyzed in the EIS. In addition, and as described in Section 3.5.1 of the EIS, the likelihood of an individual migratory bat encountering the rotor swept zone of one or more operating WTGs is negligible. For this reason, the analysis provided in the EIS is sufficient to support sound scientific judgments and informed decision making related to the distribution and use of the offshore portions of the geographic analysis area, as well as to the potential for collision risk of migratory bats. Further, the similarity between the layouts analyzed for the different alternatives does not render any of this incomplete and unavailable information essential to a reasoned choice among alternatives. Therefore, BOEM did not identify incomplete or unavailable scientifically based information on bat resources that is essential to a reasoned choice among alternatives.

## Benthic Habitat and Invertebrates

Although there is some uncertainty regarding the temporal distribution of benthic resources and periods during which they might be especially vulnerable to disturbance, site-specific benthic habitat mapping by Inspire Environmental (2021) and other broadscale studies (e.g., Fugro 2019, 2021; Guida et al. 2017; Stantec 2020) provided a suitable basis for predicting the species, community composition, and distributions of benthic resources in the geographic analysis area. Some uncertainty also exists about the effects of some impact-producing factors (IPFs) on benthic resources. For example, the available information on invertebrate sensitivity to electromagnetic fields (EMFs) is equivocal (Hutchinson et al. 2020), and sensitivity to sound pressure and particle motion effects is not well understood for all species (e.g., squid sensitivity to vibration effects transmitted through sediments). However, information from monitoring studies of European wind facilities and, more recently, the Block Island Wind Farm in the United States provides no indication of biologically significant adverse effects. There is broader uncertainty about the long-term effects of changes in biological productivity resulting from the creation of new habitat types on the mid-Atlantic Outer Continental Shelf (OCS) in the form of a distributed network of artificial reefs. The widespread development of offshore renewable energy facilities would, however, create a distributed network of artificial reefs on the mid-Atlantic OCS. These reefs form biological hotspots that could support species range shifts and expansions, nonnative species, and changes in biological community structure (Degraer et al. 2020; Methratta and Dardick 2019; Raoux et al. 2017). The nature and significance of secondary synergistic effects, such as changes in diet and predator-prey interactions resulting from habitat modification in combination with other IPFs, are not fully known. Lastly, the nature, extent, and significance of potential spillover effects on broader ecosystem functions, such as larval dispersal, are not fully understood (van Berkel et al. 2020).

As stated, ongoing monitoring studies at European wind facilities and the Block Island Wind Farm in the United States provide a useful basis for evaluating the combined effects of these IPFs on the biological community as a whole, even if effects on individual species cannot be predicted with specificity. On balance, the current scientific information is sufficient to support sound scientific judgements and informed decision making because relevant studies monitoring changes at wind farms have not observed significant changes to finfish over years of study. Further, the similarity between the layouts analyzed for the different alternatives does not render any of this incomplete and unavailable information essential to a reasoned choice among alternatives. Therefore, BOEM did not identify incomplete or unavailable information that is essential to a reasoned choice among alternatives. There is uncertainty regarding the spatial and temporal occurrence of invertebrates throughout the entire benthic habitat and invertebrates geographic analysis area. However, broadscale information is available from sources such as federal fisheries management plans (FMPs) and surveys completed to support COP submission. There is also uncertainty regarding behavioral effects from each IPF individually and cumulatively. Again, BOEM is able to draw on existing scientific findings, as presented in Section 3.6 of the EIS and references therein. The available information is suitable for characterizing the likely effects of each IPF and has been used to analyze potential impacts resulting from the proposed Project and past, present, and reasonably foreseeable actions. Therefore, BOEM concludes that the available information about potential impacts on benthic habitats supports a reasoned choice among alternatives.

## Birds

Habitat use and distribution of birds vary between seasons, species, and years, and as a result, there will always be some level of incomplete information on the distribution and habitat use of birds in the offshore portions of the birds geographic analysis area. However, survey findings for the Project (see COP Appendix K [*Onshore Natural Resources and Biological Assessment*] [VHB 2023]) were used to inform the predictive models and analyze the potential adverse impacts on bird resources in the EIS. In addition, because U.S. offshore wind is in its infancy, as described above for bats, there will always be some level of uncertainty regarding the potential for collision risk and avoidance behaviors for some of the bird species that may be present within the offshore portions of the geographic analysis area.

Bird mortality data are available for onshore wind facilities, and based on a number of assumptions (described in Section 3.7 of the EIS) regarding their applicability to offshore environments, these data were used to inform the analysis of bird mortality associated with the offshore WTGs analyzed in the EIS. However, uncertainties exist regarding the use of the onshore bird mortality rate to estimate offshore bird mortality rate because of differences in species groups present, the life history and behavior of species, and the differences in the offshore marine environment compared to onshore habitats. Similarly, the U.S. Fish and Wildlife Service biological assessment (BA) (BOEM 2022, 2023a) also provides an estimate of potential mortality using the Band (2012) collision risk model for Endangered Species Act species. Modeling is commonly used to predict the potential mortality rates for marine bird species in Europe and the United States (BOEM 2015, 2022). Because of inherent data limitations, these models often represent only a subset of species potentially present. However, the datasets used by both Revolution Wind, LLC (Revolution Wind), and BOEM to assess the potential for exposure of birds to offshore wind activities represent the best available data and provide context at both local and regional scales. Further, sufficient information on collision risk and avoidance behaviors observed in related species at European offshore wind projects is available and was used to analyze and corroborate the potential for these impacts as a result of the Project (e.g., Petersen et al. 2006; Skov et al. 2018). For this reason, the analysis provided in the EIS is sufficient to support sound scientific judgements and informed decision making related to distribution and use of the offshore portions of the analysis area, as well as to the potential for collision risk and avoidance behaviors in bird resources. Further, the similarity between the layouts analyzed for the different alternatives does not render any of this incomplete and unavailable information essential to a reasoned choice among alternatives. Therefore, BOEM did not identify incomplete or unavailable information on bird resources that is essential to a reasoned choice among alternatives.

## Coastal Habitats and Fauna

Although the preferred areas of coastal habitats and associated fauna are generally known, exact abundances and distributions of various fauna are likely to remain unknown for the foreseeable future. However, the species inventories and other information from nearby areas provide an adequate basis for evaluating the fauna likely to inhabit the coastal habitat and fauna geographic analysis area. Additionally, the onshore activities proposed involve only common, industry-standard activities for which impacts are generally understood. For this reason, BOEM identified no incomplete or unavailable information required to conduct the impact assessment or to make a reasoned choice among alternatives.

## Commercial Fisheries and For-Hire Recreational Fishing

Fisheries are managed in the context of an incomplete understanding of fish stock dynamics and effects of environmental factors on fish populations. The fisheries information used in this assessment has limitations. For example, vessel trip report data are only an approximation because they are self-reported, and available historical data lack consistency, making comparisons challenging. However, these data do represent the best available data, and sufficient information exists to support the findings presented herein.

A second limitation is that aggregated geographic information system (GIS)–based data is necessary to fully update the revenue intensity figures. EIS Figures G-CF1 through G-CF13 in Appendix G provide low-resolution images of revenue intensity by FMP and provide graphic representations of the distribution of fishing efforts near the Lease Area for the years shown. However, similar revenue intensity figures are not available for ports or gear. Although the analysis in EIS Section 3.9 refers to these figures, annual vessel trip report data for 2008 to 2019 from the Greater Atlantic Regional Fisheries Office (GARFO) (2021) were the primary sources of data used in the tables throughout the assessment. These tables in EIS Section 3.9 summarize harvests and revenues by FMP, by ports, and by gears within the RWF and Revolution Wind Export Cable. Although additional revenue intensity figures would augment information provided in the analysis, BOEM determined this information is not essential to a reasoned choice among alternatives.

## Cultural Resources

BOEM is applying NEPA Substitution for the steps in the National Historic Preservation Act Section 106 process under 36 Code of Federal Regulations 800.8, facilitating BOEM's good faith effort to identify historic properties and assess effects prior to construction. The record of decision (ROD) will apply to the alternative(s) selected by BOEM. BOEM will execute a memorandum of agreement before issuing the ROD and would require that the memorandum of agreement specify that measures for avoiding, minimizing, and mitigation adverse effects to historic properties be implemented for the selected alternative following ROD issuance. Therefore, BOEM has not identified incomplete or unavailable information on cultural resources that is essential to a reasoned choice among alternatives.

## Demographics, Employment, and Economics

Estimates of local employment and income resulting from development and construction of the Project may be underestimated because the broadly used model to project the employment impacts of offshore wind energy development—the Jobs and Economic Development Impact Offshore Wind Model (JEDI-OWM) developed by the National Renewable Energy Laboratory (NREL)—has not been updated to include recent developments within the U.S. offshore wind component manufacturing and fabrication industry, despite NREL's recent updates to capital cost estimation portions of the JEDI-OWM.[2]

The COP and COP appendices do provide estimates of a capital and operating cost of a single configuration of RWF (with 89 8-megawatt [MW] WTGs and a nameplate capacity of 712 MW) along with an estimate of economic impacts to the United States and local economies of Rhode Island and Connecticut based on the 2017 version of the JEDI-OWM. It is presumed that Revolution Wind provided specific guidance to their economic analysts with respect to technical and cost parameters, as well as United States and local spending coefficients for this assessment. However, most of the specific technical details of the assessment were not provided to BOEM or to the authors of the EIS. Therefore, estimates of economic impacts of the development and construction of RWF under the range of EIS alternatives rely heavily on the economic impacts developed in the COP relative to estimates of capital and operating costs of the single configuration provided.

Because Revolution Wind provided the baseline estimates of economic impacts of the Project, and because other information from NREL's updated JEDI-OWM model[2] provides current estimates of

[2] An updated version of JEDI-OWM was made available in 2021. The portions of the JEDI-OWM used to estimate capital operational costs have been updated and include cost estimates of large WTGs (12 MW and 15 MW) that are likely to be employed in future offshore windfarms. However, the 2021 version of the model does not provide local purchase coefficients that are needed to estimate economic impacts. In addition, NREL has not yet published a user manual or a methodological report for the 2021 version. The economic impact estimates used in the demographic, employment, and economics section of the EIS are augmented by improved capital cost estimates in the new release, but continue to employ U.S. and local spending patterns included in the 2017 version of the JEDI-OWM.

capital costs of offshore wind farms with WTGs ranging up to 15 MW, BOEM determined that the lack of directly provided information with respect to other configurations is not essential to a reasoned choice among alternatives.

There is also uncertainty regarding the distribution of economic impacts among geographic areas, income brackets, and other sub-components of the economy. These effects will depend on how the Project supply chain evolves, the contracts that are ultimately entered into, and provisions with the Project's power purchase agreements and state laws. Much of this uncertainty is inherent at this stage of the Project. In addition, BOEM has used appropriate methods to estimate economic impacts given the available information. Therefore, additional information regarding the distribution of impacts among sub-components of the economy is not essential to a reasoned choice among alternatives.

## Environmental Justice

Evaluations of impacts on environmental justice communities rely on the assessment of impacts on other resources. As a result, incomplete or unavailable information related to other resources, as described in this document, also affect the completeness of the analysis of impacts on environmental justice communities. However, BOEM has determined that the incomplete and unavailable resource information summarized in this appendix was either not relevant to a reasoned choice among alternatives or the alternative data or methods used to predict potential impacts provided the best available information. Therefore, the analysis provided in the EIS is sufficient to support sound scientific judgments and informed decision making related to the proposed uses of the onshore and offshore portions of the environmental justice analysis area.

## Finfish and Essential Fish Habitat

Monitoring studies of European and American offshore wind energy facilities to date (Hutchison et al. 2020; Raoux et al. 2017; Reubens et al. 2013, 2014) provide no indication of biologically significant adverse effects on finfish and their habitats. However, broader uncertainty remains about the long-term effects of changes in biological productivity resulting from the creation of new habitat types along the Atlantic OCS in the form of a distributed network of artificial reefs (Degraer et al. 2020). The nature and significance of potential ecological responses, such as changes in diet and predator-prey interactions resulting from changes in habitat productivity, are not fully known. Lastly, the nature, extent, and significance of potential spillover effects on broader ecosystem functions, such as seasonal stratification of the Cold Pool and larval dispersal patterns, are not fully understood (Johnson et al. 2021; van Berkel et al. 2020). Targeted modeling studies suggest that the effects of offshore wind development in the RI/MA and MA WEAs on water column stratification and larval dispersal patterns are unlikely to be ecologically significant (Johnson et al. 2021). However, this study considered only two out of several WEAs in the geographic analysis area, meaning that the potential effects resulting from full build-out of all WEAs within the geographic analysis area remain to be studied.

As stated, ongoing monitoring studies at European wind facilities and the Block Island Wind Farm in the United States provide a useful basis for evaluating the combined effects of these IPFs on the biological community as a whole, even if effects on individual species cannot be predicted with specificity. On balance, the current scientific information is sufficient to support sound scientific judgements and informed decision making because relevant studies monitoring changes at wind farms have not observed significant changes in finfish abundance and distribution at regional scales over years of study. For example, while wind farm installation can displace soft-bottomed habitat in favor of hard substrates, the affected areas usually represent a small fraction of available habitat. Moreover, offshore wind structures provide habitat complexity that generally results in an increase in biological productivity, which in turn can attract fish species that associate with complex habitat types (Degraer et al. 2020). Therefore, while some uncertainty remains, the available information does not suggest that long-term negative effects are likely. The similarity between the layouts analyzed for the different alternatives does not render any of this incomplete and unavailable information essential to a reasoned choice among alternatives.

There is uncertainty regarding the spatial and temporal occurrence of finfish and essential fish habitat (EFH) throughout the entire finfish and EFH geographic analysis area. This is especially true for Atlantic cod (*Gadus morhua*) use of the Coxes Ledge area, which is part of an ongoing study funded by BOEM examining the movements of commercial fish species in southern New England (National Oceanic and Atmospheric Administration [NOAA] 2020a). However, broadscale information is available from sources such as federal FMPs and from surveys completed to support COP submission. There is also uncertainty regarding behavioral effects from each IPF individually and cumulatively (e.g., operational noise effects on Atlantic cod communication during spawning). Again, BOEM is able to draw on existing scientific findings, as presented in Section 3.13 of the EIS and references therein, in the RWF EFH assessment (BOEM 2023b, 2023c), and in the National Marine Fisheries Service (NMFS) BA (BOEM 2023d, 2023e). The available information is suitable for characterizing the likely effects of each IPF and has been used to analyze potential impacts resulting from the Project and past, present, and reasonably foreseeable actions. For this reason, the analysis provided in the EIS is sufficient to support sound scientific judgments and informed decision making related to the proposed uses of the offshore portions of the geographic analysis area. Further, the similarity between the layouts analyzed for the different alternatives does not render any of this incomplete and unavailable information essential to a reasoned choice among alternatives. Therefore, BOEM concluded that the available information about potential impacts on finfish and EFH supports a reasoned choice among alternatives.

## Land Use and Coastal Infrastructure

There is no incomplete or unavailable information related to the analysis of impacts on land use and coastal infrastructure.

## Marine Mammals

Although there is some uncertainty regarding the temporal distribution of marine mammals and periods during which they might be especially vulnerable to Project disturbance, the NMFS BA (BOEM 2023d, 2023e) provides detailed species descriptions and life history information. NOAA has summarized the most current information about marine mammal population status, occurrence, and use of the region in their 2019 and 2020 stock status reports for the Atlantic OCS and Gulf of Mexico (Hayes et al. 2020, 2021). These studies provide a suitable basis for predicting the species, abundances, and distributions of marine mammals in the geographic analysis area.

Uncertainty also exists with regard to the effects of some IPFs on marine mammals. For example, there is still some uncertainty regarding the impacts on marine mammals from EMF produced by submarine cables. This uncertainty is due in part to difficulties in evaluating population-scale impacts around regional deployments (Taormina et al. 2018), to the large size and high mobility of marine mammals, and to other logistical constraints, which make experimental studies infeasible. As a result, no scientific studies have been conducted to examine the effects of altered EMF on marine mammals. Although scientific studies summarized by Normandeau Associates, Inc., et al. (2011) demonstrate that marine mammals are sensitive to and can detect small changes in magnetic fields, as described in Section 3.15 of the EIS, those potentially detectable impacts would only occur within a few feet of select cable segments. There is no basis to conclude that the potential detection of EMFs would lead to any measurable change in behavior. For this reason, the analysis provided in the EIS is sufficient to support sound scientific judgments and informed decision making related to the proposed uses of the offshore portions of the geographic analysis area.

Some uncertainty also exists regarding the cumulative acoustic impacts associated with pile-driving activities. The available information relative to impacts on marine mammals from pile driving associated with offshore wind development is primarily limited to information on harbor porpoise (*Phocoena phocoena*) and harbor seal (*Phoca vitulina*) because most of this research has occurred at European offshore wind projects, where large whales are uncommon. At this time, it is unclear if marine mammals would cease feeding and when individuals would resume normal feeding, migrating, breeding, etc., behaviors once daily pile-driving activities cease, or if secondary indirect impacts would persist. Certain species, notably North Atlantic right whale (*Eubalaena glacialis*), rely on specialized feeding strategies that appear to be sensitive to disruption (van der Hoop et al. 2019). These findings suggest that short-term behavioral disturbance could contribute to energy deficits that ultimately lead to reduced fitness (Fortune et al. 2013; van der Hoop et al. 2019). Under the cumulative impact scenario, individual whales may be exposed to acoustic impacts from multiple projects in 1 day or to acoustic impacts from one or more projects over multiple days. The consequences of these exposure scenarios have been analyzed with the best available information, but a lack of real-world observations on species' responses to pile-driving results is uncertain. Additionally, it is currently unclear how sequential years of construction of multiple projects would impact marine mammals. Future projects will undergo a project-specific analysis under NEPA, the Endangered Species Act, and the Marine Mammal Protection Act that may reach different impact conclusions from this analysis if warranted based on new scientific and potentially observable information, or if impacts are defined differently from the EIS.

There is also uncertainty about certain potential impacts on marine mammals resulting from the long-term presence of offshore wind structures in the environment. For example, operational WTGs would generate low-frequency underwater noise that may exceed the established minimum threshold for potential behavioral and auditory masking impacts within a short distance (e.g., approximately 120 feet) from each foundation, although detectable noise above ambient levels could extend up to 560 feet or more. These structures would contribute to and potentially increase ambient noise within each WEA, albeit at levels generally not associated with adverse effects on marine mammals. However, the 120 root mean square decibels ($dB_{RMS}$) threshold may not adequately represent the potential for adverse effects of chronic noise exposure (e.g., Cholewiak et al. 2018; Hatch et al. 2012; Jensen et al. 2009; Putland et al. 2017). The implications of long-term operational noise impacts and structure presence on marine mammal behavior, particularly the behavior of large whale species, are unclear. These potential impacts are topics of ongoing research.

There is broader uncertainty about how large whales will respond to the presence of extensive networks of novel offshore wind structures on the Atlantic OCS. Under the cumulative impact scenario, up to 3,110 new structures (i.e., WTGs and OSSs) could be constructed across the geographic analysis area. Although the planned spacing of structures would not obstruct whale movement between structures, the potential synergistic effects of structure presence and low-level operational noise are uncertain. There is also some uncertainty around reef effect and hydrodynamic impacts on prey and forage availability and predator-prey interactions. Additionally, these impacts could combine and interact with ongoing changes in marine species distribution and community composition driven by climate change. Displacement effects that result in increased interactions between vulnerable populations of marine mammals and commercial shipping and/or fishing activity could have significant long-term cumulative effects. The potential consequences of these impacts on the Atlantic OCS are unknown. Monitoring studies could be able to track these changes and observe how they may influence whale behavior. At present, BOEM has no basis to conclude that these IPFs would result in significant adverse impacts on any marine mammal species.

At present, currently available information suggests that hydrodynamic effects of foundation structures are likely to be localized and not additive when spaced at 1 nm in environments with strong seasonal stratification (van Berkel et al. 2020). Recent modeling of hydrodynamic effects suggests that surface currents could be affected by the presence of multiple wind farms potentially impacting the distribution of larvae (Johnson et al. 2021). There is insufficient information to determine if this conclusion is valid for broader scale development at the levels planned within the geographic analysis area.

BOEM determined that the overall costs of obtaining the missing information for or addressing uncertainty of the above topics for marine mammals are exorbitant or that the means to obtain it are not known. Therefore, BOEM extrapolated or drew assumptions from known information for similar species and/or situations, as presented in Section 3.15 of the EIS and in the BA submitted to NMFS (BOEM 2023d, 2023e). As a result, the information and methods used to predict potential impacts on marine mammals represent the best available information, and the analysis provided in the EIS is sufficient to support sound scientific judgments and informed decision making related to the proposed uses of the offshore portions of the geographic analysis area. Notwithstanding the foregoing, the similarity between the layouts analyzed for the different alternatives does not render any of this incomplete and unavailable information essential to a reasoned choice among alternatives. Therefore, BOEM has not identified incomplete or unavailable scientific information on marine mammal resources that is essential to a reasoned choice among alternatives.

## Navigation and Vessel Traffic

The navigation and vessel traffic impact analysis in the EIS is based on automatic identification system (AIS) data for calendar year 2019. Vessel monitoring system (VMS) data for fishing vessels provided by the NMFS were the basis for polar histograms and other analytical outputs used in evaluating commercial and for-hire recreational fishing trips (see EIS Section 3.9). Some smaller recreational and fishing vessels carry an AIS; however, the AIS analysis likely excludes most vessels less than 65 feet (19.8 meters) long that traverse the WEA. In addition, as discussed under Commercial Fisheries and For-Hire Recreational Fishing, above, the VMS data provided by NMFS indicate the number of vessels in each fishery and their direction of travel while actively fishing, which speaks to alignment of the WTG grid. Nonetheless, the combination of AIS and VMS data described above represent the best available vessel traffic data and are sufficient to enable BOEM to make a reasoned choice among alternatives.

The U.S. Coast Guard's (USCG's) final report for the Areas Offshore of Massachusetts and Rhode Island Port Access Route Study (MARIPARS), evaluating the need for establishing vessel routing measures, was published in the *Federal Register* on May 27, 2020 (USCG 2020). The MARIPARS report recommends a standard and uniform grid pattern turbine layout throughout the Rhode Island and Massachusetts Lease Areas as the best way to facilitate predictable safe navigation throughout the contiguous leases. The five Rhode Island and Massachusetts offshore wind leaseholders, including Revolution Wind, have proposed a collaborative regional layout for wind turbines (1 × 1 nm apart in fixed east–west rows and north–south columns, with 0.7-nm theoretical transit lanes oriented northwest–southeast) across their respective BOEM leases (Geijerstam et al. 2019), which meets the layout rules set forth in the MARIPARS report recommendations. Although the USCG attached to the MARIPARS *Federal Register* docket the Responsible Offshore Development Alliance proposal (Hawkins 2020), which recommends additional transit corridors through the Lease Areas, the MARIPARS report concludes that if the layout in the recommendations was implemented, the USCG would likely not pursue additional formal or informal routing measures. As a cooperating agency with BOEM, the USCG would continue to consult over the course of the NEPA process for the Project as it relates to navigational safety and other aspects, including the impacts associated with alternatives assessed. Therefore, BOEM has not identified incomplete or unavailable information on navigation and vessel traffic that is essential to a reasoned choice among alternatives.

## Other Marine Uses

In the context of this EIS, other marine uses include aviation and air traffic, land-based radar, marine mineral resources and dredged material disposal, military and national security, offshore energy (aside from the proposed Project), scientific research and surveys, and undersea cables. There is no incomplete or unavailable information related to the analysis of marine mineral resources and dredged material disposal, military and national security, aviation and air traffic, offshore energy (aside from the aspects described in this appendix for the proposed Project, and the reasonably foreseeable offshore wind projects for which BOEM has not received COPs), undersea cables, and land-based radar uses.

As discussed in Section 3.17 of the EIS for scientific research and surveys, analysis in the EIS discloses both Project-specific and cumulative impacts to NMFS's ability to continue conducting scientific research and surveys for the purpose of fisheries management and protected species management. Despite the foregoing, BOEM has concluded that the information provided by NOAA in Section 3.17 regarding scientific research and surveys is sufficient to support the impact findings presented in the EIS. Therefore, BOEM has not identified incomplete or unavailable information on scientific research and surveys that is essential to a reasoned choice among alternatives.

## Recreation and Tourism

There is a lack of quantitative data related to recreational not-for-hire fishing in the recreation and tourism geographic analysis area; therefore, quantitative analysis for this resource is not possible at this time. BOEM is considering how best to approach this issue for future similar projects. *Fisheries Economics of the United States 2018* (NMFS 2021) is a comprehensive summary document and the data presented discuss the overall economic level for not-for-hire recreational anglers in the offshore New England region (Maine, New Hampshire, Rhode Island, Connecticut, and Massachusetts). However, the document does not relate to how projects such as the RWF are likely to affect not-for-hire recreational fishing and is not detailed enough in geographic extent to discuss specific recreational angling locations.

However, BOEM has determined that incomplete and unavailable resource information was either not relevant to a reasoned choice among alternatives or alternative data or methods used to predict potential impacts provided the best available information. Therefore, the analysis provided in the EIS is sufficient to support sound scientific judgments and informed decision making related to the proposed uses of the onshore and offshore portions of the geographic analysis area.

## Sea Turtles

Sea turtles are difficult to observe in the open ocean, and there is some uncertainty about the distribution of some turtle species (e.g., the green sea turtle [*Chelonia mydas*]) in relation to the Lease Area. The NMFS BA (BOEM 2023d, 2023e) provides a thorough overview of the available information about potential species occurrence and exposure to Project-related IPFs. The studies summarized therein provide a suitable basis for predicting potential species occurrence, relative abundance, and probable distribution of sea turtles in the geographic analysis area.

Some uncertainty exists about the effects of certain IPFs on sea turtles and their habitats. For example, sea turtle sensitivity to potential EMF effects from the Project is not fully understood. Sea turtles are known to use the earth's magnetic field to orient in space and navigate between habitats (Irwin and Lohmann 2005; Courtillot et al. 1997). However, the available research has not examined how sea turtles respond to lower strength EMF levels on the order of those likely to result from the Project. Although there are no direct data on impacts on sea turtles from EMFs generated by underwater cables, the preponderance of evidence summarized in the BOEM-sponsored report by Normandeau et al. (2011) indicates that sea turtles are unlikely to detect most of the EMF impacts resulting from the Project. Potentially detectable EMF effects would be limited to within 5 feet of the short segments of cable laid on the seafloor that are not buried. Section 3.19 of the EIS and the NMFS BA (BOEM 2023d, 2023e) allowed BOEM's subject matter experts to estimate the potential risk to other species of sea turtles based on the assumption of similar anatomical, behavioral, and life history similarities, related to EMFs. Although the thresholds for EMF disturbance to the behavior of all potential species of sea turtles are not known, no adverse effects on sea turtles from the numerous submarine power cables around the world have been documented, and modeling of the anticipated EMFs generated by Project components suggests the majority of induced field strengths would likely be below detection levels. Similar to marine mammals, data are also not available to evaluate potential changes to normal movements of juvenile and adult sea turtles due to short-term elevated suspended sediments. Although some exposure may occur, total suspended sediment impacts would be limited in magnitude and duration and within the range of natural exposures periodically experienced by these species. On this basis, any resulting impact on behavior would likely be too small to be biologically meaningful, and no adverse impacts would be expected (NOAA 2020b).

There is also uncertainty relative to sea turtle responses to construction activities on the Atlantic OCS. Some potential for displacement from areas exposed to noise and disturbance exists. However, should displacement of individuals occur, it is unclear if this would result in adverse impacts (e.g., because of lost foraging opportunities or increased exposure to potentially fatal vessel interactions). Additionally, it is unclear whether concurrent construction of multiple projects, increasing the extent and intensity of impacts over a shorter duration or spreading out project construction, and associated impacts over multiple years would result in the least potential harm to sea turtles. There is also uncertainty regarding the cumulative acoustic impacts associated with pile driving. At this time, it is unclear if sea turtles that have ceased feeding during multiple construction activities would resume normal feeding, migrating, breeding, etc., behaviors once daily pile driving ceases or if secondary indirect impacts would continue. Under the cumulative impact scenario, individual sea turtles may be exposed to acoustic impacts from multiple projects in 1 day or to acoustic impacts from one or more projects over multiple days. The consequences of these exposure scenarios have been analyzed with the best available scientific information in EIS Section 3.19, although some level of uncertainty remains due to the lack of observational data on species responses to pile driving. In addition, modeled predictions of operational sound for large turbines (10 MW) indicate that sound levels could be greater than observed for existing wind turbines; actual sound levels are still predicted to be well below levels that could cause harm.

Some uncertainty exists in regard to the potential for sea turtle responses to Federal Aviation Administration hazard lights and navigation lighting associated with offshore wind development. Given the placement of the new structures far from nesting beaches and within the OCS, no impacts to nesting female or hatchling sea turtles would be expected. Revolution Wind has incorporated BOEM’s guidance (BOEM 2021; Orr et al. 2013) for avoiding and minimizing artificial lighting impacts on aquatic life into the Project design. This environmental protection measure would limit WTG and electrical service platform lighting to minimum levels required by regulation for worker safety, navigation, and aviation. Sea turtle sensitivity to these minimal light levels is unknown. However, given that sea turtles do not appear to be adversely affected by oil and gas platform operations, which produce far more artificial light than offshore wind structures (BOEM 2023d, 2023e), this IPF is not expected to have any measurable impacts (adverse or beneficial) on sea turtles in the offshore environment.

More broadly, considerable uncertainty remains about how sea turtles would interact with long-term changes in biological productivity and community structure resulting from the development of an extensive network of artificial reefs across the geographic analysis area. Artificial reef and hydrodynamic impacts could influence predator-prey interactions and foraging opportunities in ways that influence sea turtle behavior and distribution. These IPFs are expected to interact with the ongoing influence of climate change on species distribution and behavior over broad spatial scales, but the nature and significance of these interactions are unclear. BOEM anticipates that ongoing monitoring of offshore energy structures will provide some useful insights into these synergistic effects. BOEM considered the level of effort required to address the uncertainties described above for sea turtles and determined that the methods necessary to do so are lacking and/or the associated costs would be exorbitant. Where appropriate, BOEM inferred conclusions about the likelihood of potential biologically significant impacts from available information for similar species and/or situations. These methods are described in detail in EIS Section 3.19 EIS and in the NMFS BA (BOEM 2023d, 2023e). The approaches and methods used are based on the best available scientific information, and the analysis provided in the EIS is sufficient to support sound scientific judgements and informed decision making related to the proposed uses of the offshore portions of the analysis area. Notwithstanding the foregoing, the similarity between the layouts analyzed for the different alternatives does not render any of this incomplete and unavailable information essential to a reasoned choice among alternatives. Therefore, BOEM does not believe that there is incomplete or unavailable information on sea turtle resources that is essential to a reasoned choice among alternatives.

## Visual Resources

There is no incomplete or unavailable information related to the analysis of impacts on visual resources.

## Water Quality

There is no incomplete or unavailable information related to the analysis of impacts on water quality.

## Wetlands and Non-tidal Waters

There is no incomplete or unavailable information related to the analysis of impacts on wetlands and non-tidal waters.

## Project Design Envelope and Maximum-Case Scenario

# Contents

# Figures

# Tables

*This page intentionally left blank.*

# Introduction

This environmental impact statement (EIS) assesses the impacts of the reasonable range of Revolution Wind Farm (RWF) and Revolution Wind Export Cable (RWEC) Project (the Project) designs that are described in the Revolution Wind construction and operations plan (COP) (VHB 2023) by using the maximum-case scenario process. The maximum-case scenario analyzes the aspects of each design parameter that would result in the greatest impact for each physical, biological, and socioeconomic resource. This EIS considers the interrelationship among aspects of the project design envelope (PDE) rather than simply viewing each design parameter independently. Additional information and guidance related to the PDE concept can be found in Chapter 1 of the EIS and on BOEM's website available at https://www.boem.gov/Draft-Design-Envelope-Guidance/. Table D-1 details the full range of maximum-case design parameters for the proposed Project and which parameters are relevant to the analysis for each EIS resource section (denoted with an *X*) in Chapter 3 of the EIS. Table D-2 and Figure D-1 detail the wind turbine generator (WTG) identification numbers and locations for the maximum-case scenario.

**Table D-1. Maximum-Case Scenario List of Parameter Specifications**

| Design Parameter | Minimum Design Size | Maximum Design Size | 3.4 Air Quality | 3.5 Bats | 3.6 Benthic Habitat and Invertebrates | 3.7 Birds | 3.8 Coastal Habitats and Fauna | 3.9 Commercial Fisheries and For-Hire Recreational Fishing | 3.10 Cultural Resources | 3.11 Demographics, Employment, and Economics | 3.12 Environmental Justice | 3.13 Finfish and Essential Fish Habitat | 3.14 Land Use and Coastal Infrastructure | 3.15 Marine Mammals | 3.16 Navigation and Vessel Traffic | 3.17 Other Marine Uses | 3.18 Recreation and Tourism | 3.19 Sea Turtles | 3.20 Visual Resources | 3.21 Water Quality | 3.22 Wetlands and Non-tidal Waters |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| **WIND FARM** | | | | | | | | | | | | | | | | | | | | | |
| Wind farm capacity | 704 megawatt (MW) | 880 MW | X | X | X | X | X | X | X | X | X | X | X | X | X | X | X | X | X | X | X |
| **WTG AND MONOPILE FOUNDATION** | | | | | | | | | | | | | | | | | | | | | |
| Turbine size | 8 MW | 12 MW | X | X | X | X | | X | X | | | X | | X | X | X | X | X | X | X | |
| Number of WTG positions | 59 | 100 | X | X | X | X | | X | X | | | X | | X | X | X | X | X | X | X | |
| Distance between positions | 1 nautical mile (nm) between WTGs on an east–west, north–south grid | 1 nm between WTGs along north–south rows, and 0.7 mile between WTGs within east–west rows | X | X | X | X | | X | X | | | X | | X | X | X | X | X | X | X | |
| Total tip height | 647.6 feet (197.4 meters [m]) | 872.7 feet (266 m) | | X | | X | | X | X | | | | | | X | X | X | | X | | |
| Hub height | 377 feet (115 m) | 512 feet (156 m) | | X | | X | | X | X | | | | | | X | X | X | | X | | |
| Turbine height | 646 feet (197 m) | 873 feet (266 m) | | X | | X | | X | X | | | | | | X | X | X | | X | | |
| Rotor diameter | 538 feet (164 m) | 722 feet (220 m) | | X | | X | | X | X | | | | | | X | X | X | | X | | |
| Base height (foundation height–top of transition piece) | 19.7 feet (6 m) | 26 feet (8 m) | | X | | X | | X | X | | | | | | X | X | X | | X | | |
| Base (tower) width (at the top) | 13 feet (4 m) | 21 feet (6.4 m) | | X | | X | | X | X | | | | | | X | X | X | | X | | |
| Nacelle dimensions (length × width × height) | 46 × 23 × 20 feet (14 × 7 × 6 m) | 72 × 33 × 39 feet (22 × 10 × 12 m) | | X | | X | | X | X | | | | | | X | X | X | | X | | |
| Rotor swept zone area | 5.2 acres (21,100 square meters [$m^2$])* | 9.7 acres (39,400 $m^2$)* | | X | | X | | X | X | | | | | | X | X | X | | X | | |

| Design Parameter | Minimum Design Size | Maximum Design Size | 3.4 Air Quality | 3.5 Bats | 3.6 Benthic Habitat and Invertebrates | 3.7 Birds | 3.8 Coastal Habitats and Fauna | 3.9 Commercial Fisheries and For-Hire Recreational Fishing | 3.10 Cultural Resources | 3.11 Demographics, Employment, and Economics | 3.12 Environmental Justice | 3.13 Finfish and Essential Fish Habitat | 3.14 Land Use and Coastal Infrastructure | 3.15 Marine Mammals | 3.16 Navigation and Vessel Traffic | 3.17 Other Marine Uses | 3.18 Recreation and Tourism | 3.19 Sea Turtles | 3.20 Visual Resources | 3.21 Water Quality | 3.22 Wetlands and Non-tidal Waters |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Blade length | 259 feet (79 m) | 351 feet (107 m) | | X | | X | | X | X | | | | | | X | X | X | | X | | |
| Blade width | 16 feet (5 m) | 26 feet (8 m) | | X | | X | | X | X | | | | | | X | X | X | | X | | |
| Base height (foundation height–top of transition piece) | 82 feet (25 m) | 128 feet (39 m) | | X | | X | | X | X | | | | | | X | X | X | | X | | |
| Air gap (mean sea level to bottom of blade tip) | 93.5 feet (28.5 m) | 151 feet (46 m) | | X | | X | | X | X | | | | | | X | X | X | | X | | |

Notes: In this appendix, distances in miles are in statute miles (miles used in the traditional sense) or nautical miles (miles used specifically for marine navigation). Statute miles are more commonly used and are referred to simply as miles, whereas nautical miles are referred to by name or by their abbreviation “nm.” Numbers that were calculated are rounded to the closest whole number.

* This value was calculated based on information provided.

# APPENDIX E

## Planned Activities Scenario and Reasonably Foreseeable Future Activities and Projects

# Contents

# Tables

*This page intentionally left blank.*

# Planned Activities Scenario

The impacts resulting from the planned activities scenario are the incremental effects of the Proposed Action on the environment added to other reasonably foreseeable planned actions in the area (40 Code of Federal Regulations [CFR] 1502.15). This appendix discusses resource-specific planned activities that could occur if Project impacts occur in the same location and time frame as impacts from other reasonably foreseeable planned actions. The *Project* here is the construction, operations and maintenance (O&M), and decommissioning of a wind energy project located within the Bureau of Ocean Energy Management's (BOEM's) Renewable Energy Lease Area OCS-A 0486, approximately 15 nautical miles (18 statute miles) southeast of Point Judith, Rhode Island and approximately 13 nautical miles (15 statute miles) east of Block Island, Rhode Island.

BOEM anticipates that impacts could occur between the start of Project construction in 2023 and the completion of Project decommissioning, which would occur within 2 years of the end of the lease (up to 35 years postconstruction). The geographic analysis area (GAA) is defined by the impact-producing factor (IPF) with the maximum geographic area of impact, for example sound during pile driving. For the mobile resources, bats, birds, finfish and invertebrates, marine mammals, and sea turtles, the species potentially impacted are those that occur within the area of impact of the Proposed Action. The GAA for these mobile resources is the general range of the species. The purpose of these analysis areas is to capture the impacts from planned activities to each of those resources potentially impacted by the Proposed Action. The GAA for each resource area is defined in the resource area sections of the environmental impact statement (EIS).

In this appendix, distances in miles are in statute miles (miles used in the traditional sense) or nautical miles (miles used specifically for marine navigation). This appendix uses statute miles more commonly and refers to them simply as *miles*, whereas nautical miles are referred to by name or abbreviation *nm*.

# Reasonably Foreseeable Future Activities and Projects

This section includes a list and description of other reasonably foreseeable activities that could contribute to cumulative impacts within the defined GAA for each resource category. Projects or actions that are considered speculative per the definition provided in 43 CFR 46.30[1] are noted in subsequent tables but excluded from the planned activities impact analysis in Chapter 3.

Planned (cumulative) activities described in this section consist of 10 types of actions: 1) other offshore wind energy development activities; 2) undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); 3) tidal energy projects; 4) marine minerals use and ocean-dredged material disposal; 5) military use; 6) marine transportation; 7) fisheries use and management; 8) global climate change; 9) oil and gas activities; and 10) onshore development activities.

[1] 43 CFR 46.30 – Reasonably foreseeable future actions include those federal and non-federal activities not yet undertaken, but sufficiently likely to occur, that a responsible official of ordinary prudence would take such activities into account in reaching a decision. The federal and non-federal activities that BOEM must take into account in the analysis of cumulative impacts include, but are not limited to, activities for which there are existing decisions, funding, or proposals identified by BOEM. Reasonably foreseeable future actions do not include those actions that are highly speculative or indefinite.

BOEM analyzed the possible extent of future other offshore wind energy development activities on the Atlantic Outer Continental Shelf (OCS) to determine reasonably foreseeable cumulative effects measured by installed power capacity. Table E-1 represents the status of projects as of March 17, 2023. The methodology for developing the scenario is largely the same as for the Vineyard Wind project (BOEM 2021a) and is outlined in the footnotes in Table E3-1.

## Monitoring and Mitigation

Future offshore wind projects could require monitoring or mitigation as part of BOEM approvals under the National Environmental Policy Act (NEPA) and OCSLA. Although specific measures are too speculative to include at this time, BOEM anticipates that measures could include actions such as passive acoustic monitoring, trawl surveys, acoustic telemetry, and gillnet or ventless trap surveys.

**Table E-1. Offshore Wind Activities on the U.S. Atlantic Coast (dates shown as of March 17, 2023)**

| Lease Number | States | Lessee/Developer Name | Project Name | Construction Date | Operations Date | Facility Description | BOEM Permitting Stage* | Power Purchase Agreement/ Offshore Renewable Energy Certificate Status |
|---|---|---|---|---|---|---|---|---|
| **Active Projects (state)** | | | | | | | | |
| N/A (state project) | Maine | New England Aqua Ventus, LLC | NE Aquaventus | 2024 | 2024 | 11 MW (1 WTG) | N/A | PPA with ME |
| N/A (state project) | Rhode Island | Deepwater Wind, LLC (now Orsted) | Block Island Wind Farm | 2015 | 2016 | 30 MW (5 WTGs) | N/A | PPA with RI |
| **Active Projects (federal)** | | | | | | | | |
| OCS-A 0483 | Virginia | Virginia Electric and Power Company (dba Dominion Virginia Power) | Coastal Virginia Offshore Wind | 2023 | 2023 | 2,500 to 3,000 MW (205 WTGs); one met buoy | SAP approved; New SAP submitted and approved; COP submitted | No PPAs signed to date |
| OCS-A 0486 | Rhode Island and Connecticut | Revolution Wind, LLC | Revolution Wind (Proposed Action) | 2024 | 2024 | Up to 880 MW (100 WTGs; two OSSs) | COP submitted; SAP approved | 2 PPAs with CT and one PPA with RI |
| OCS-A 0487 | New York | Sunrise Wind LLC | Sunrise Wind | 2024 | 2024 | Up to 934 MW (94WTGs) | COP submitted | OREC awarded by NYSERDA (PPA with NY) |
| OCS-A 0490 (portion) | Maryland | U.S. Wind Inc. | U.S. Wind | 2024 | 2024 | Up to 2,000 MW (121 WTGs) | COP submitted; SAP approved | OREC awarded by State of Maryland |
| OCS-A 0497 | Virginia | Virginia Department of Mines, Minerals and Energy ( | Coastal Virginia Offshore Wind | 2021 | 2021 | 12 MW (two WTGs-6 MW each); one wave/current buoy | Operating | N/A (research) |
| OCS-A 0498 (portion) | New Jersey | Ocean Wind, LLC | Ocean Wind 1 | 2024 | 2025 | 1,100 MW (98 WTGs) | COP submitted<br>SAP approved | OREC awarded by NJ |
| OCS-A 0499 | New Jersey | Atlantic Shores Offshore Wind, LLC | Atlantic Shores | 2025 | 2025 | Up to 1,510 MW (105 to 136 WTGs) | SAP approved; COP submitted | OREC signed with NJ for 1,510 MW. |
| OCS-A 0500 (portion) | Massachusetts | Bay State Wind LLC | Bay State Wind | 2026 | 2027 | 800 MW; two FLIDAR buoys; one met buoy | COP in progress<br>SAP approved | No PPA signed to date |
| OCS-A 0501 (north) | Massachusetts | Vineyard Wind LLC | Vineyard Wind 1 | 2023 | 2023 | 800 MW (62 WTGs); two met buoys | ROD issued | PPA with MA |
| OCS-A 0534 and portion of OCS-A 0501 | Massachusetts | New England Wind, LLC | Park City Wind (Phase 1)<br>Commonwealth Wind (Phase 2) | 2024 | 2026 | Up to a combined 2,284 MW (130 WTGs or ESP) positions) for both phases | COP in progress | PPA with CT (Phase 1)<br>No PPA signed to date (Phase 2) |
| OCS-A 0508 | North Carolina, Virginia | Kitty Hawk Wind, LLC | Kitty Hawk North Wind | 2027 | 2027 | Up to 1,242 MW (69 WTGs; up to two buoys; and up to two platforms | COP submitted; SAP approved | No PPA signed to date |

| Lease Number | States | Lessee/Developer Name | Project Name | Construction Date | Operations Date | Facility Description | BOEM Permitting Stage* | Power Purchase Agreement/ Offshore Renewable Energy Certificate Status |
|---|---|---|---|---|---|---|---|---|
| OCS-A 0508 (remainder) | Virginia/North Carolina | Kitty Hawk Wind, LLC | Kitty Hawk Wind, South | 2027 | 2028 | Up to 2,178 MW (121 WTGs) | SAP approved; COP in progress | No PPAs signed to date |
| OCS-A 0512 ) | New York | Empire Offshore Wind LLC | Empire Wind 1,<br>Empire Wind 2 | 2024 | 2027 | Up to 2,176 MW (147 WTGs); two met buoys; one wave/met buoy; one subsea current meter mooring | COP submitted; SAP approved | PPA with NY |
| OCS-A 0517 | New York | South Fork Wind, LLC | South Fork Wind Farm | 2023 | 2023 | 130 MW (up to 12 WTGs); one met buoy | ROD issued<br>COP approved | PPA with NY |
| OCS-A 0519 (portion) | Delaware, Maryland | Skipjack Offshore Energy, LLC | Skipjack | 2024 | 2024 | 192 MW (up to 16 WTGs); one met buoy | COP in progress | OREC awarded by State of Maryland (connection to PJM grid in DE) |
| OCS-A 0521 | Massachusetts | Mayflower Wind Energy, LLC | South Coast Wind | 2024 | 2024 | Up to 1,600–2,400 MW (147 WTGs); one met buoy | SAP approved; COP submitted | PPA with MA (up to 804 MW)<br>Applying for other PPAs |
| OCS-A 0520 | Massachusetts | Beacon Wind, LLC | Beacon Wind (Phase 1)<br>Beacon Wind (Phase 2) | 2024–2027 | 2026–2029 | Up to 2,330 MW (188 WTGs) | SAP submitted; COP in progress | No PPA signed to date |

# Offshore Wind Energy Development Activities

## Site Characterization Studies

A lessee is required to provide the results of site characterization activities with its site assessment plan (SAP) or COP. For the purposes of the planned activities effects analysis, BOEM makes the following assumptions for survey and sampling activities (BOEM 2016):

- Site characterization would occur on all existing leases.
- Site characterization would likely take place in the first 3 years following execution of a lease, since a lessee would likely want to generate data for its COP at the earliest possible opportunity.
- Lessees would likely survey most or all of the proposed lease area during the 5-year site assessment term to collect required geophysical information for siting of a meteorological tower and/or two buoys and commercial facilities (wind turbines). The surveys may be completed in phases, with the meteorological tower and/or buoy areas likely to be surveyed first.
- Lessee would not use air guns, which are typically used for deep penetration two-dimensional or three-dimensional exploratory seismic surveys to determine the location, extent, and properties of oil and gas resources.

Table E-2 summarizes the typical site characterization surveys, the types of equipment and/or method used, and which resources the survey information would inform (BOEM 2013, 2016).

**Table E-2**. **Typical Site Characterization Survey Information**

| Survey Type | Survey Equipment and/or Method | Resource Surveyed or Information Used to Inform |
|---|---|---|
| High-resolution geophysical surveys | Side-scan sonar, sub-bottom profiler, magnetometer, multi-beam echosounder | Shallow hazards, archaeological, Bathymetric charting, benthic habitat |
| Geotechnical/ sub-bottom sampling | Vibracores, deep borings, cone penetration tests | Geological |
| Biological | Grab sampling, benthic sled, underwater imagery/ sediment profile imaging | Benthic habitat |
| | Aerial digital imaging; visual observation from boat or airplane | Bird |
| | Ultrasonic detectors installed on survey vessels used for other surveys | Bat |
| | Visual observation from boat or airplane | Marine fauna (marine mammals and sea turtles) |
| | Direct sampling of fish and invertebrates | Fish |

Source: BOEM (2016).

## Site Assessment Activities

After SAP approval, a lessee can evaluate the meteorological conditions, such as wind resources, with the approved installation of meteorological towers and/or buoys. Site assessment activities have been approved or are in the process of being approved for multiple lease areas consisting of one to three meteorological buoys per SAP (see Table E-1). Site assessment would likely take place starting within 1 to 2 years of lease execution, because preparation of a SAP (and subsequent BOEM review) takes time. This planned activities analysis considers these site assessment activities.

## Construction and Operation of Offshore Wind Facilities

Table E-1 lists all offshore wind leasing activities that BOEM considers reasonably foreseeable by lease areas and projects, their permitting stage/assessment, and anticipated timeline.

### Commercial Fisheries Cumulative Fishery Effects Analysis

Table E-3 summarizes 1) the incremental number of construction locations that are projected to be active in each region during each year between 2021 and 2030; 2) the number of operational turbines in each region at the beginning of each year between 2021 and 2030; and 3) the total number of active construction locations and operational turbines across the Atlantic OCS by year.

# Incorporation by Reference of Cumulative Impacts Study

BOEM has completed a study of IPFs on the North Atlantic OCS to consider in an offshore wind development cumulative impacts scenario (BOEM 2019), which is incorporated by reference. The study identifies cause-and-effect relationships between renewable energy projects and resources and classifies those relationships into a manageable number of IPFs through which renewable energy projects could affect resources. It also identifies the types of actions and activities to be considered in a cumulative impacts scenario. The study identifies actions and activities that may affect the same physical, biological, economic, or cultural resources as renewable energy projects and states that such actions and activities may have the same IPFs as offshore wind projects.

The BOEM (2019) study identifies the relationships between IPFs associated with specific past, present, and reasonably foreseeable actions and activities in the North Atlantic OCS, which were incorporated into this EIS analysis. If an IPF was not associated with the RWF Project, it was not included in the impacts analysis of planned activities.

As discussed in the BOEM (2019) study, reasonably foreseeable activities other than offshore wind projects may also affect the same resources as the Project or other offshore wind projects, possibly via the same IPFs or via IPFs through which offshore wind projects do not contribute. This appendix lists reasonably foreseeable non-offshore wind activities that may contribute to the cumulative impacts of the proposed Project.

# Undersea Transmission Lines, Gas Pipelines, and Other Submarine Cables

The following existing undersea transmission lines, gas pipelines, and other submarine cables are located near the Project:

- New Shoreham (Block Island), Rhode Island, is served by a submarine power cable from the Block Island Wind Farm to New Shoreham (Block Island).
- A submarine power cable connects Block Island to the mainland electrical grid at Narragansett, Rhode Island.
- Service to Martha’s Vineyard is provided by four electric cables from Falmouth, located in three corridors through Vineyard Sound. Two cables are located in the same corridor between Elm Road in Falmouth and West Chop: one is located between Shore Street in Falmouth and Eastville (East Chop), and one connects between Mill Road in Falmouth and West Chop.
- Two cables service Nantucket through Nantucket Sound, from Dennis Port and Hyannis Port to landfall at Jetties Beach.
- Additional submarine cables, including fiber-optic cables and trans-Atlantic cables that originate near Charlestown, Rhode Island; New York City; Long Island, near Trenton, New Jersey; and Wall, New Jersey, are located offshore New England and mid-Atlantic states, but outside the proposed Lease Area.

- Two natural gas pipelines are located offshore Boston, Massachusetts, in Massachusetts Bay and lead to liquified natural gas (LNG) export facilities: the Neptune pipeline and the Northeast Gateway LNG pipeline.

The offshore wind projects listed in Table E-1 that have a COP under review are presumed to include at least one identified cable route. Cable routes have not yet been announced for the remainder of the proposed wind energy projects in Table E-1.

## Tidal Energy Projects

The following tidal energy projects have been proposed or studied on the U.S East Coast and are in operation or considered reasonably foreseeable:

- The Bourne Tidal Test Site, located in the Cape Cod Canal near Bourne, Massachusetts, is a testing platform for tidal turbines that was installed in late 2017 by the Marine Renewable Energy Collaborative. The Bourne Tidal Test Site offers a test platform for tidal turbines (MRECo 2017, 2018).
- Cobscook Bay Tidal Project, located in Maine, is a Federal Energy Regulatory Commission-(FERC) licensed tidal project that began operations in 2012. The project owner, Ocean Power Energy Company, has informed FERC that it will not apply for relicensing, and removal and site restoration activities are anticipated to be conducted prior to its current license expiration date in January 2022 (FERC 2012a).
- Western Passage Tidal Energy Project, a proposed tidal energy site in the Western Passage, received a preliminary permit from FERC in 2016. The preliminary permit allows developers to study a project but does not authorize construction.
- The Roosevelt Island Tidal Energy (RITE) Project located in the East Channel of the East River, a tidal strait connecting the Long Island Sound with the Atlantic Ocean in the New York Harbor. In 2005, Verdant Power petitioned FERC for permission to the first U.S. commercial license for tidal power. In 2012, FERC issued a 10-year license to install up to 1 MW of power (30 turbines/10 TriFrames) at the RITE project (FERC 2012b; Verdant Power 2018).

## Dredging and Port Improvement Projects

The following dredging projects have been proposed or studied between New York, New York, and Boston, Massachusetts, and are either in operation or are considered reasonably foreseeable:

- The U.S. Army Corps of Engineers (USACE) New England District partnership with Rhode Island Coastal Resources Management Council (RI CRMC) proposes a project that would dredge approximately 23,700 cubic yards of sandy material from the Point Judith Harbor Federal Navigation Project to widen the existing 15-foot-deep mean lower low water (MLLW) West Bulkhead channel by 50 feet and extend the same channel approximately 1,200 feet into the North Basin area (USACE 2018a).
- The Plymouth Harbor Federal Navigation Project in Plymouth, Massachusetts, includes maintenance dredging of approximately 385,000 cubic yards of sand and silt from approximately

75 acres of the authorized project area in order to restore the project to authorized and maintained dimensions (USACE 2018b).

- The Port of New Bedford was awarded a $15.4 million U.S. Department of Transportation Better Utilizing Investments to Leverage Development grant to improve the port's infrastructure and to help with the removal of contaminated materials. The funding will be used to extend the port's bulkhead, creating room for 60 additional commercial vessels, and additional sites for offshore wind staging (Phillips 2018).
- The Port of New Bedford is currently developing the Foss Marine Terminal, which will provide an additional full-service base of operations and terminal logistics facility to support offshore wind projects off Massachusetts and the northeastern seaboard (New Bedford Port Authority 2022). The New Bedford Foss Marine Terminal will provide storage and laydown yards for equipment and materials, berth facilities for tug and barge operations, and will host crew transfer vessel and service operation vessel support services. The redevelopment will also create new office space for project teams and a marine coordination center for technicians involved in offshore wind projects. Construction of the terminal facility is anticipated to be completed in the spring 2023.
- Proposed New Haven Harbor Improvements would include deepening the main ship channel, maneuvering area, and turning basin to -40 feet MLLW and widening the main channel and turning basin to allow larger vessels to efficiently access the Port of New Haven’s terminals. The proposed improvements would remove approximately 4.28 million cubic yards of predominately glacially deposited silts from the federal channel (USACE 2018c).
- The Nature Conservancy seeks a permit to place an artificial reef array in Narraganset Bay at 130 Shore Road in Narragansett Bay in East Providence, Rhode Island. The proposed work involves the construction of a 0.14-acre artificial reef using 91 pre-fabricated reef modules. The artificial reef array would consist of 58 Pallet Balls (4.0 × 2.9 feet) and 33 Bay Balls (3 × 2 feet). The reef modules would be transported to the project site by barge and lowered to the seafloor by crane (USACE 2019).
- The RI CRMC has awarded funding for five habitat restoration projects in the 19th year of its Rhode Island Coastal and Estuarine Habitat Restoration Trust Fund (RI CRMC 2022). These projects comprise a dam removal assessment, streambank stabilization on the Woonasquatucket River, salt marsh restoration, habitat restoration and invasive species management, and fish passage improvement on the Saugatucket River (RI CRMC 2018a).
- The Town of Dennis seeks a permit for the selective dredging of multiple navigation and mooring basins within multiple waterways in the towns of Dennis and Yarmouth. Suitable dredged material will be used as nourishment on multiple town-owned beaches in Dennis whereas material that is not deemed suitable for beach nourishment will be disposed of at the Cape Cod Bay Disposal Site and at the South Dennis Landfill. The town is requesting to dredge approximately 434,310 cubic yards from portions of these waterways over 10 years encompassing an area of approximately 96.03 acres (USACE 2018d).

The following port improvement projects have been proposed in Connecticut, Rhode Island, Massachusetts, and/or New Jersey, and are either in operation or are considered reasonably foreseeable:

- The Connecticut Port Authority (CPA) announced a $93 million public-private partnership to upgrade the Connecticut State Pier in New London to support the offshore wind industry (Sheridan 2019). According to the Connecticut Maritime Strategy 2018 (CPA 2018a), New London is the only major port between New York and Maine that does not have vertical obstruction and offshore barriers, two factors that are critical for offshore wind turbine assembly. The document includes strategic objectives to manage and redevelop the Connecticut State Pier partially to support the offshore wind industry, which could create a dramatic increase in demand for the Connecticut State Pier and regional job growth. The development partnership, announced in May 2019, includes a 3-year plan to upgrade infrastructure to meet heavy-lift requirements of Orsted and Eversource offshore wind components (Cooper 2019). Redevelopment of the Connecticut State Pier is considered a reasonably foreseeable activity.
- In Rhode Island, Revolution Wind, LLC has committed to investing approximately $40 million in improvements at the Port of Providence, the Port of Davisville at Quonset Point, and possibly other Rhode Island ports for the Revolution Wind Project (Kuffner 2018). This investment will position Rhode Island ports to participate in construction and operation of future offshore wind projects in the region (Rhode Island Governor's Office 2018). The Port of Davisville has added a 150-megaton mobile harbor crane, which will enable the port to handle wind turbines and heavy equipment, and enables the Port of Davisville to participate in regional offshore wind projects (Port of Davisville 2017). Further improvements at Rhode Island ports to support the offshore wind industry are considered reasonably foreseeable.
- The Massachusetts Clean Energy Center (MassCEC) has identified 18 waterfront sites in Massachusetts that may be available and suitable for use by the offshore wind industry. Potential activities at these sites include manufacturing of offshore wind transmission cables, manufacture and assembly of turbine components, substation manufacturing and assembly, O&M bases, and storage of turbine components (MassCEC 2017a, 2017b, 2017c).
- The MassCEC manages the New Bedford Marine Commerce Terminal in New Bedford, Massachusetts. The 29-acre facility was completed in 2015 and is the first in North America designed specifically to support the construction, assembly, and deployment of offshore wind projects (MassCEC 2018). The New Bedford Port Authority Strategic Plan 2018–2023 contains goals related to expanding the New Bedford Marine Commerce Terminal to improve and expand services to the offshore wind industry, including development of North Terminal with the capacity to handle two separate offshore wind installation projects in the future (Port of New Bedford 2018). Vineyard Wind signed an 18-month lease with the Marine Commerce Terminal in October 2018 (Port of New Bedford 2020) and has supported the New Bedford Port Authority with grants to develop publicly owned facilities to support shore-based operations for offshore wind facilities (Vineyard Wind 2019).

## Marine Minerals Use and Ocean Dredged Material Disposal

The closest active lease in BOEM's Marine Minerals Program for sand borrow areas for beach replenishment is located offshore New Jersey near Harvey Cedars, Surf City, Long Beach Township, Ship Bottom, and Beach Haven (Lease Number OCS-A-0505) (BOEM 2018).

In addition, reconnaissance and/or design-level OCS studies along the East Coast from Rhode Island to Florida have identified potential future sand resources. Sand resources identified nearest the Project include locations offshore Rhode Island (between Block Island and Charlestown), Long Island (Rockaway Beach, Long Beach, and Fire Island, New York), and Sandy Hook, New Jersey.

The EPA Region 1 is responsible for designating and managing ocean disposal sites for materials offshore in the region of the Project. The USACE issues permits for ocean disposal sites; all ocean sites are for the disposal of dredged material permitted or authorized under the Marine Protection, Research, and Sanctuaries Act (16 United States Code [USC] 1431 et seq. and 33 USC 1401 et seq.). There are nine active projects along the Massachusetts, Rhode Island, Connecticut, and New York coasts, with the closest dredge disposal project, the Rhode Island Sound Disposal Site, located northeast of Block Island (USACE 2018e).

## Military Use

Military activities can include various vessel training exercises, submarine and antisubmarine training, and U.S. Air Force exercises. The U.S. Navy, the U.S. Coast Guard (USCG), and other military entities have numerous facilities in the region. Major onshore regional facilities include Joint Base Cape Cod, Naval Station Newport, Newport Naval Undersea Warfare Center, Naval Submarine Base New London, and USCG Academy (BOEM 2013; Epsilon Associates, Inc 2018; RI CRMC 2010). The U.S. Atlantic Fleet also conducts training and testing exercises in the Narraganset Bay Operating Area, and the Newport Naval Undersea Warfare Center routinely performs testing in the area (BOEM 2013).

## Marine Transportation

Marine transportation in the region is diverse and sourced from many ports and private harbors from New York to Massachusetts. Commercial vessel traffic in the region includes research, tug/barge, liquid tankers (such as those used for liquid petroleum), cargo, military and search-and-rescue vessels, and commercial fishing vessels. Recreational vessel traffic includes cruise ships, sailboats, and charter boats. A number of federal agencies, state agencies, educational institutions, and environmental non-governmental organizations participate in ongoing research offshore including oceanographic, biological, geophysical, and archaeological surveys.

One new regional maritime highway project that has received funding from the U.S. Department of Transportation (USDOT) Maritime Administration (MARAD) is a new barge service (Davisville/Brooklyn/ Newark Container-on-Barge Service). This service is proposed to run twice each week in state waters between Newark, New Jersey; Brooklyn, New York; and the Port of Davisville in Rhode Island (USDOT MARAD 2021), which is located on Quonset Point, one of the potential O&M locations. The project received grant funding from MARAD in August 2018 (fiscal year 2017) to purchase material for handling equipment for the biweekly barge service (USDOT MARAD 2022).

## National Marine Fisheries Service Activities

Research and enhancement permits may be issued for marine mammals protected by the Marine Mammal Protection Act (MMPA) and for threatened and endangered species under the ESA. The National Marine Fisheries Service (NMFS) is anticipated to continue issuing research permits under section 10(a)(1)(A) of the ESA to allow take of certain ESA-listed species for scientific research. Scientific research permits issued by NMFS currently authorize studies on ESA-listed species in the Atlantic Ocean, some of which occur in portions of the Lease Area. Current fisheries management and ecosystem monitoring surveys conducted by or in coordination with the Northeast Fisheries Science Center (NEFSC) could overlap with offshore wind lease areas in the New England region and south into the Mid-Atlantic region. Surveys include 1) the NEFSC Bottom Trawl Survey, a more than 50-year multispecies stock assessment tool using a bottom trawl; 2) the NEFSC Sea Scallop/Integrated Habitat Survey, a sea scallop stock assessment and habitat characterization tool, using a bottom dredge and camera tow; 3) the NEFSC Surfclam/Ocean Quahog Survey, a stock assessment tool for both species using a bottom dredge; and 4) the NEFSC Ecosystem Monitoring Program, a more than 40-year shelf ecosystem monitoring program using plankton tows and conductivity, temperature, and depth units. These surveys are anticipated to continue within the region, regardless of offshore wind development.

The regulatory process administered by NMFS, which includes stock assessments for all marine mammals and 5-year reviews for all ESA-listed species, assists in informing decisions on take authorizations and the assessment of project-specific and cumulative impacts that consider past, present, and reasonably foreseeable future actions in biological opinions. Stock assessments completed regularly under MMPA include estimates of potential biological removal that stocks of marine mammals can sustainably absorb. MMPA take authorizations require that a proposed action have no more than a negligible impact on species or stocks, and that a proposed action impose the least practicable adverse impact on the species. MMPA authorizations are reinforced by monitoring and reporting requirements so that NMFS is kept informed of deviations from what has been approved. Biological opinions for federal and non-federal actions are similarly grounded in status reviews and conditioned to avoid jeopardy and to allow continued progress toward recovery. These processes help to ensure that, through compliance with these regulatory requirements, a proposed action would not have a measurable impact on the conservation, recovery, and management of the resource.

### Directed Take Permits for Scientific Research and Enhancement

NMFS issues permits for research on protected species for scientific purposes. These scientific research permits include the authorization of directed take for activities such as capturing animals and taking measurements and biological samples to study their health, tagging animals to study their distribution and migration, photographing and counting animals to get population estimates, taking animals in poor health to an animal hospital, and filming animals. NMFS also issues permits for enhancement purposes; these permits are issued to enhance the survival or recovery of a species or stock in the wild by taking actions that increase an individual’s or population’s ability to recover in the wild. In waters near the Lease Area, scientific research and enhancement permits have been issued previously for satellite, acoustic, and multi-sensor tagging studies on large and small cetaceans, research on reproduction, mortality, health, and conservation issues for North Atlantic right whales, and research on population dynamics of harbor and gray seals. Reasonably foreseeable future impacts from scientific research and enhancement permits include physical and behavioral stressors (e.g., restraint and capture, marking, implantable and suction tagging, biological sampling).

### Fisheries Use and Management

NMFS implements regulations to manage commercial and recreational fisheries in federal waters, including those within which the Project would be located; the State of New York, state of Rhode Island, and Commonwealth of Massachusetts regulate commercial fisheries in state waters (within 3 nautical miles of the coastline). There are several aquaculture sites in Narragansett Bay; however, the Lease Area and the RWEC centerline does not intersect any of these sites (Suffolk County 2018). The closest aquaculture site to the RWEC centerline is located on the western shoreline of Conanicut Island, approximately 1,427 feet (435 m) from the RWEC route centerline (VHB 2023).

The project overlaps two of NMFS' eight regional councils to manage federal fisheries: Mid-Atlantic Fishery Management Council (MAFMC), which includes New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia and North Carolina; and New England Fishery Management Council (NEFMC), which includes Maine, New Hampshire, Massachusetts, Rhode Island, and Connecticut (NEFMC 2016). The councils manage species with many fishery management plans that are frequently updated, revised, and amended and coordinate with each other to jointly manage species across jurisdictional boundaries (MAFMC 2019). Many of the fisheries managed by the councils are fished for in state waters or outside of the Mid-Atlantic region, so the council works with the Atlantic States Marine Fisheries Commission (ASMFC). ASMFC is composed of the 15 Atlantic coast states and coordinates the management of marine and anadromous resources found in the states' marine waters. In addition, the lobster and Jonah crab fisheries are cooperatively managed by the states and NMFS under the framework of the ASMFC (2019).

The fishery management plans of the councils and ASMFC were established, in part, to manage fisheries to avoid overfishing. They accomplish this through an array of management measures, including annual catch quotas, minimum size limits, and closed areas. These various measures can further reduce (or increase) the size of landings of commercial fisheries in the Northeast and the Mid-Atlantic regions.

NOAA Fisheries also manages highly migratory species (HMS), such as tuna and sharks, that can travel long distances and cross domestic boundaries.

## Global Climate Change

Section 7.6.1.4 of the *Programmatic Environmental Impact Statement for Alternative Energy Development and Production and Alternate Use of Facilities on the Outer Continental Shelf* (Minerals Management Service [MMS] 2007) describes global climate change with respect to assessing renewable energy development. Climate change is predicted to affect Northeast fishery species differently (Hare et al. 2016), and the NMFS biological opinion discusses in detail the potential impacts of global climate change on protected species that occur within the proposed action area (NMFS 2013).

The Intergovernmental Panel on Climate Change (IPCC) released a special report in October 2018 that compared risks associated with an increase of global warming of 1.5 degrees Celsius (°C) and an increase of 2°C. The report found that climate-related risks depend on the rate, peak, and duration of global warming, and that an increase of 2°C was associated with greater risks associated with climatic changes such as extreme weather and drought; global sea level rise; impacts to terrestrial ecosystems; impacts to marine biodiversity, fisheries, and ecosystems and their functions and services to humans; and impacts to health, livelihoods, food security, water supply, and economic growth (IPCC 2018).

States and regions look to offshore wind as a key component in their strategic plans to meet emissions goals in part because offshore wind can provide a low-carbon/no-carbon electricity supply source for current and increasing needs of electrified heating and transportation. Offshore wind projects produce less net greenhouse gas (GHG) emissions over the life of the projects when compared to other energy sources currently in use. Table E-4 summarizes regional plans and policies that are in place to address climate change, and Table E-5 summarizes resiliency plans.

### Table E-4. Climate Change Plans and Policies

| Plans and Policies | Summary/Goal |
|---|---|
| **Connecticut** | |
| 2008 Global Warming Solutions Act | Sets forth statutory requirements to reduce GHG emissions 10% below 1990 levels by 2020 and 80% below 2001 levels by 2050 (State of Connecticut 2008). |
| Control of Carbon Dioxides Emissions/$CO_2$ Budget Trading Program (2008) | Sets forth statutory requirements to establish a carbon dioxide ($CO_2$) allowance tracking system wherein $CO_2$ allowance allocations are established under the Connecticut $CO_2$ Budget Trading Program Base Budget. Budget sources are identified, cataloged, monitored and reported, transferred, and tracked under a certification program in an effort to cap and reduce power sector $CO_2$ emissions. |
| Regional Greenhouse Gas Initiative (RGGI) (2009) | The nation's first mandatory, market-based cap-and-trade program to reduce emissions of $CO_2$. Under the program, which began in 2009, participating RGGI states (Rhode Island, Connecticut, Delaware, Massachusetts, Maryland, Maine, New Hampshire, New York, Vermont, and New Jersey; New Jersey withdrew in 2011) established a regional cap on $CO_2$ emissions from fossil fuel–fired electric generating facilities, and required these power plants to possess a tradable $CO_2$ allowance for each ton of $CO_2$ they emit. Under RGGI, $CO_2$ allowances are distributed through quarterly allowance auctions. |
| An Act Concerning Electric and Fuel Cell Electric Vehicles (Public Act 16-135) (2016) | Sets forth several provisions related to electric vehicles (EVs), including requirements related to data collection, EV charging stations, and electric rate structures. |
| Building A Low Carbon Future for Connecticut: Achieving a 45% GHG reduction by 2030 (2018) | Proposed set of strategies to achieve 45% GHG reduction below 2001 levels target by 2030. These strategies ensure Connecticut is on a downward trajectory to the 80% reduction target by 2050 required by the Global Warming Solutions Act (State of Connecticut 2018a). |
| 2018 Act Concerning Climate Change Planning and Resiliency (Public Act 18-82) | Act passed by the Connecticut General Assembly that adopted GC3's recommendation of 45% GHG mid-term reduction target below 2001 levels by 2030 and integrates GHG reduction more explicitly into the DEEP Comprehensive Energy Strategy (CES) and Integrated Resource Plan (IRP) (State of Connecticut 2018b). |
| Comprehensive Energy Strategy (CES) (2018) | Connecticut Department of Energy and Environmental Protection (DEEP) update to Connecticut's CES to advance the State's goal of creating a cheaper, cleaner, more reliable energy future for Connecticut's residents and businesses. The CES analyzes energy use and key trends of the region (State of Connecticut 2018c) |
| Executive Order No. 3, (2019) | Re-establishes and expands the membership and responsibilities of the Governor's Council on Climate change (GC3), originally established in 2015. Orders GC3 to report to the Governor regarding the state's progress on the implementation of the strategies identified in *Building a Low Carbon Future for Connecticut: Achieving a 45% GHG reduction by 2030* (State of Connecticut 2019) |

| Plans and Policies | Summary/Goal |
|---|---|
| Integrated Resources Plan (2020) | DEEP is required to prepare an Integrated Resource Plan (IRP) every 2 years, which is comprised of an assessment of the future electric needs and a plan to meet those future needs. Executive Order 3 directed DEEP to analyze pathways and recommend strategies to achieve a 100 percent zero carbon electric supply by 2040 in this IRP (State of Connecticut 2020). |
| Taking Action on Climate Change and Building a More Resilient Connecticut for All (2021) | Phase 1 report in response to Executive Order 3's request for progress on mitigation strategies and preparation of an Adaptation and Resilience Plan. Provides information on GC3 members and Working Group members, GC3 background and process, the Equity and Environmental Justice Working Group, the impacts of climate change in Connecticut, and recommendations for near-term action (State of Connecticut 2021) |
| **Massachusetts** | |
| Global Warming Solutions Act (GWSA) of 2008 | Framework to reduce GHG emissions by requiring 25% reduction in emissions from all sectors below 1990 baseline emission level in 2020, at least 80% reduction in 2050. Full implementation of these policies is projected to result in total net reduction of 25.0 million metric tons of $CO_2$ equivalent, or 26.4% below 1990 baseline level (Commonwealth of Massachusetts 2018a). |
| Massachusetts Clean Energy and Climate Plan (CECP) for 2020; 2015 CECP Update | Policies that aim to reduce GHG emissions in the commonwealth across all sectors; full implementation of policies would result in reducing emissions by at least 25% below 1900 level in 2020 (Commonwealth of Massachusetts 2015). |
| Executive Order 569, Establishing an Integrated Climate Strategy for the Commonwealth and "Act to Promote Energy Diversity" (2016) | Calls for large procurements of offshore wind and hydroelectric resources (Commonwealth of Massachusetts 2016). |
| Environmental Bond Bill and An Act to Advance Clean Energy (2018) | Sets new targets for offshore wind, solar, and storage technologies; expands Renewable Portfolio Standard requirements for 2020–2029; establishes a Clean Peak Standard; and permits fuel switching in energy efficiency programs (Commonwealth of Massachusetts 2018a). |
| Massachusetts State Hazard Mitigation and Climate Adaption Plan 2018 | Updated 2013 plan to comprehensively integrate climate change impacts and adaptation strategies with hazard mitigation planning while complying with federal requirements for state hazard mitigation plans and maintaining eligibility for federal disaster recovery and hazard mitigation funding under the Stafford Act. The plan will next be submitted to the Federal Emergency Management Agency (FEMA) for approval. In 2020, a new 2030 emissions limit and CECP for 2030 will be published (Commonwealth of Massachusetts 2018a, 2018b). |
| Massachusetts 2050 Decarbonization Roadmap | A planning process by the Massachusetts Executive Office of Energy and Environmental Affairs to identify cost-effective and equitable strategies to ensure Massachusetts reduces GHG emissions by at least 85% by 2050 and achieves net-zero emissions (Commonwealth of Massachusetts 2020a) |

| Plans and Policies | Summary/Goal |
|---|---|
| Massachusetts Clean Energy and Climate Plan (CECP) for 2030 | The Clean Energy and Climate Plan for 2030 (2030 CECP) provides details on the actions the Commonwealth will undertake through the next decade to ensure the 2030 emissions limit is met. The 2030 CECP is prepared in coordination with the development of the 2050 Decarbonization Roadmap such that the strategies, policies, and actions outlined in the 2030 CECP can help the Commonwealth achieve net zero GHG emissions by 2050. The Interim 2030 CECP was built upon the 2020 CECP and the 2015 CECP Update (Commonwealth of Massachusetts 2020b). |
| 2030 GHG Emissions Limit | The 2030 emissions limit of 45% below the 1990 GHG emissions level was set on December 30, 2020, in accordance with Executive Order 569 to help the Commonwealth meet the 2050 emissions limit (Commonwealth of Massachusetts 2020c) |
| Net Zero by 2050 Emissions Limit | A 2050 statewide emissions limit of net zero GHG emissions was established by the Commonwealth. This is defined as a level of statewide GHG emissions that is equal in quantity to the amount of $CO_2$ or its equivalent that is removed from the atmosphere and stored annually by, or attributable to, the Commonwealth; provided, however, that in no event shall the level of emissions be greater than a level that is 85 percent below the 1990 level (Commonwealth of Massachusetts 2020d). |
| **New York** | |
| Reforming the Energy Vision (New York State 2014) | State's energy policy to build integrated energy network; Clean energy goal to reduce GHGs by 40% by 2030 and by 80% by 2050. |
| Order Adopting a Clean Energy Standard (State of New York Public Service Commission 2016) | Requirement that 50% of New York's electricity come from renewable energy sources by 2030. |
| New York State Energy Plan 2015; 2017 Biennial Report to 2015 Plan (New York State Energy Research Development Authority [NYSERDA] 2015, 2017a) | Requires 40% reduction in GHGs from 1990 levels; 50% electricity will come from renewable energy resources; and 600 trillion British thermal units (Btu) increase in statewide energy efficiency. |
| Governor Cuomo State of State Address 2017, 2018, 2021 | 2017: Set offshore wind energy development goal of 2,400 MW by 2030 (Governor's Office 2017a).<br>2018: Procurement of at least 800 MW of offshore wind power between two solicitations in 2018 and 2019; new energy efficiency target for investor-owned utilities to more than double utility energy efficiency progress by 2025; energy storage initiative to achieve 1,500 MW of storage by 2025 and up to 3,000 MW by 2030 (Governor's Office 2018a, 2018b).<br>2021: The governor's 2021 agenda—Reimagine \| Rebuild \| Renew—establishes a goal of building out its renewable energy program. The agenda notes the development of two new offshore wind farms more than 20 |

| Plans and Policies | Summary/Goal |
|---|---|
| | miles off the shore of Long Island, the creation of dedicated offshore port facilities, and additional transmission capacity development. |
| New York State Offshore Wind Master Plan (2017) (NYSERDA 2017b) | Grants NYSERDA ability to award 25-year long-term contracts for projects ranging from approximately 200 MW to approximately 800 MW, with an ability to award larger quantities if sufficiently attractive proposals are received. Each proposer is also required to submit at least one proposal of approximately 400 MW. Bids are due in February 2019, awards are expected in spring 2019; and contracts are expected to be executed thereafter. |
| 2020 Offshore Wind Solicitation | As noted above, NYSERDA has provisionally awarded two offshore wind projects, totaling 2,490 MW. Empire Wind 2 (1,260 MW) and Beacon Wind (1,230 MW) of Equinor Wind US LLC will generate enough clean energy to power 1.3 million homes and will be major economic drivers, supporting the following:<br>More than 5,200 direct jobs<br>Combined economic activity of $8.9 billion in labor, supplies, development, and manufacturing statewide<br>$47 million in workforce development and just access funding |
| The Climate Leadership and Community Protection Act (CLCPA), enacted on July 18, 2019, signed into law in July 2019 and effective January 1, 2020 | CLCPA establishes economy-wide targets to reduce GHG emissions by 40% of 1990 levels by 2030 and 85% of 1990 levels by 2050. |
| **Rhode Island** | |
| Air Pollution Control Regulation No. 37-Rhode Island's Low-Emission Vehicle Program (2001) | The purpose of this regulation is to specify the requirements for Rhode Island's Low-Emission Vehicle Program to reduce motor vehicle GHG emissions. |
| Air Pollution Control Regulation No. 46, 'CO2 Budget Trading Program' (2008) | The purpose of this regulation is to establish the Rhode Island component of the $CO_2$ Budget Trading Program, which is designed to reduce anthropogenic emissions of $CO_2$ from the $CO_2$ budget sources in an economically efficient manner. Budget sources are identified, cataloged, monitored and reported, transferred, and tracked under a certification program in an effort to cap and reduce power sector $CO_2$ emissions. |
| RGGI (2009) | The RGGI is the nation's first mandatory, market-based cap-and-trade program to reduce emissions of $CO_2$. Under the program, which began in 2009, Rhode Island receives $CO_2$ allowance proceeds, which are invested in a variety of consumer benefit programs, including energy efficiency, renewable energy, direct energy bill assistance and other GHG reduction programs. |

| Plans and Policies | Summary/Goal |
|---|---|
| Resilient Rhode Island Act (2014) | Established the Executive Climate Change Coordinating Council (EC4) and set specific GHG reduction targets; incorporates consideration of climate change impacts into the powers and duties of all state agencies (State of Rhode Island 2014). |
| Energy 2035 Rhode Island State Energy Plan (2015) | Long-term comprehensive strategy for energy services across all sectors using a secure, cost-effective, and sustainable energy system; plan to increase sector fuel diversity, produce net economic benefits, and reduce GHG emissions by 45% by the year 2035 (State of Rhode Island 2015b). |
| Governor's Climate Priorities (2018) Executive Order 15-17, 17-06 | Increasing in-state renewable energy tenfold by 2020 (to 1,000 MWs) through new development and regional procurement (State of Rhode Island 2015a, 2017, 2018a). |
| Rhode Island Greenhouse Gas Emissions Reductions Plan (2016) | Targets for GHG reductions: 10% below 1990 levels by 2020; 45% below 1990 levels by 2035; 80% below 1990 levels by 2040 (State of Rhode Island 2016). |
| Resilient Rhody (2018) | Planning document outlining climate resiliency actions; focuses on leveraging emissions reduction targets and adaptation (State of Rhode Island 2018b). |
| Executive Order 20-01, Advancing a 100% Renewable Energy Future for Rhode Island by 2030 | Calls the Rhode Island Office of Energy Resources (OER) to conduct economic and energy market analyses to develop an actionable plan to reach 100% renewable electricity by 2030. The OER must provide this specific and implementable action plan by December 31, 2020 (State of Rhode Island 2020a). |
| The Road to 100% Renewable Electricity by 2030 in Rhode Island | Provides economic analysis of the key factors that will guide Rhode Island in the coming years as the state accelerates its adoption of carbon-free renewable resources. The OER developed specific policy, programmatic, planning, and equity-based actions that will support achieving the 100% renewable electricity goal (Rhode Island OER 2020). |
| 2021 Act on Climate | This legislation updates Rhode Island's climate-emission reduction goals laid out in the 2014 Resilient RI Act and address areas such as environmental injustices, public health inequities, and a fair employment transition as fossil-fuel jobs are replaced by green energy jobs. The state will develop a plan to incrementally reduce climate emissions to net-zero by 2050 and is to be updated every 5 years (State of Rhode Island 2020b). |

### Table E-5. Resiliency Plans and Policies in the Lease Area

| Plans and Policies | Summary |
|---|---|
| **Connecticut** | |

| Plans and Policies | Summary |
|---|---|
| Act Authorizing Municipal Climate Change and Coastal Resiliency Reserve Funds (CCCRRF) (Public Act 19-77) | Act approved July 1, 2019. Upon the recommendation of the chief elected official and budget-making authority, and approval of the legislative body of a municipality, the reserve fund may be used and appropriated to pay for municipal property losses, capital projects and studies related to mitigating hazards and vulnerabilities of climate change including, but not limited to, land acquisition (Connecticut General Assembly 2019). |
| Resilient Connecticut | Connecticut Institute for Resilience & Climate Adaptation (CIRCA) was awarded an $8 million from the National Disaster Relief Competition(NDRC) to develop the *Resilient Connecticut* project. Coordination of CIRCA, state agencies, and regional councils of governments and municipalities initiated the development of a Planning Framework to establish resilient communities through smart planning that incorporates economic development framed around transit-oriented development, conservation strategies, and critical infrastructure improvements (Resilient Connecticut (CIRCA 2021). |
| An Act Concerning Climate Change Adaptation (Public Act 21-115) | Act approved July 6, 2021. This proposal addresses the rising seas, frequent flooding, heat waves, and drought expected between now and 2050. It prioritizes the protection of frontline vulnerable communities and provides Connecticut's communities more options to move from adaptation and resilience planning to implementing their project pipeline, including the use of nature-based and green infrastructure solutions (Connecticut General Assembly 2021). |
| **Massachusetts** | |
| Municipal Vulnerability Preparedness grant program (MVP) (2017) | Provides support for cities and towns to plan for resiliency and implement key climate change adaptation actions for resiliency. The City of New Bedford has received MVP designation as of November 1, 2018 (Commonwealth of Massachusetts 2019a). |
| Coastal Grant and Resilience Program | Provides financial and technical support for local efforts to increase awareness and understanding of climate impacts, identify and map vulnerabilities, conduct adaptation planning, redesign vulnerable public facilities and infrastructure, and implement non-structural approaches that enhance natural resources and provide storm damage protection (Commonwealth of Massachusetts 2019b). |
| General Appropriations Bill, FY2022 (Section 2000-0101) | Designation of funds for the Executive Office of Energy and Environmental Affairs to coordinate and implement strategies for climate change adaptation and preparedness, including, but not limited to, resiliency plans for the commonwealth in a report to be delivered by February 3, 2022 (Commonwealth of Massachusetts Legislature 2021). |
| Nantucket's Coastal Resilience Plan | The plan is currently under development, and while no actions have been identified to date, potential shoreline management activities could include sediment management, construction of seawalls and similar structures, and other activities (Town and County of Nantucket 2018a, 2018b). |

| Plans and Policies | Summary |
|---|---|
| **New York** | |
| Part 490 of Community Risk and Resiliency Act (CRRA) of 2014 | Establishes statewide science-based sea-level rise projections for coastal regions of the state. As of 2019, DEC is in the process of developing a State Flood Risk Management Guidance document for state agencies (New York State Department of Environmental Conservation [NYSDEC] n.d. [2019]). |
| NY Rising Community Reconstruction (2018) | $20.4 million in projects on Long Island to help flood-prone communities plan and prepare for extreme weather events as they continue projects to recover from Superstorm Sandy, Hurricane Irene, and Tropical Storm Lee. Three projects were announced for Suffolk County and five for Nassau County (Governor's Office 2018b). |
| Water Infrastructure Improvement Act (WIIA), Water Quality Improvement Project (WQIP) Program, and Intermunicipal Grant (IMG) | $600 million available to communities statewide for programs to fund projects to upgrade infrastructure and make communities more resilient to flooding and other impacts of climate-driven severe storms and weather events (Governor's Office 2021). |
| **Rhode Island** | |
| Shoreline Change Special Area Management Plan (Beach SAMP) | The RI CRMC developed and adopted the Beach SAMP to improve the state's resilience and manage the shoreline (RI CRMC 2018b). |
| **Regional** | |
| New England Governor's and Eastern Canadian Premiers (NEG/ECP) Regional Climate Change Initiative | The NEG/ECP Regional Climate Change Initiative includes seven New England states (Connecticut, Maine, Massachusetts, New Hampshire, New York, Rhode Island, and Vermont). This initiative encourages advancement of regional discussions and collaborative efforts to reduce greenhouse gas emissions by identifying strategies, policies, and measures through which the region could achieve its 2030 reduction marker and 2050 target (NEG/ECP 2022). |

## Oil and Gas Activities

The Project would be located in the North Atlantic Planning Area of the OCS Oil and Gas Leasing Program (National OCS Program). On September 8, 2020, the White House issued a presidential memorandum for the Secretary of the Interior on the withdrawal of certain areas of the U.S. OCS from leasing disposition for 10 years, including the areas currently designated by BOEM as the South Atlantic and Straits of Florida Planning Areas (The White House 2020a). The South Atlantic Planning Area includes the OCS off South Carolina, Georgia, and northern Florida. On September 25, 2020, the White House issued a similar memorandum for the Mid-Atlantic Planning Area that lies south of the northern administrative boundary of North Carolina (The White House 2020b). This withdrawal prevents consideration of these areas for any leasing for purposes of exploration, development, or production during the 10-year period beginning July 1, 2022, and ending June 30, 2032. However, at this time, there has been no decision by the Secretary of the Interior regarding future oil and gas leasing in the North Atlantic or remainder of the Mid-Atlantic Planning Areas. Existing leases in the withdrawn areas are not affected.

BOEM issues geological and geophysical (G&G) permits to obtain data for hydrocarbon exploration and production; locate and monitor marine mineral resources; aid in locating sites for alternative energy structures and pipelines; identify possible human-made, seafloor, or geological hazards; and locate potential archeological and benthic resources. G&G surveys are typically classified into the following categories by equipment and survey type:

- Deep-penetration seismic air gun surveys (2-D, 3-D, 4-D, ocean-bottom nodal, and azimuth multi-vessel surveys)
- Air gun HRG surveys that are used to investigate the shallow subsurface for geohazards (also known as shallow hazard surveys) and that are used during initial site evaluation, drilling rig emplacement, and platform or pipeline design and emplacement
- Electromagnetic surveys, deep stratigraphic and shallow test drilling, and various remote-sensing methods
- Non-air gun HRG surveys (similar to those used to support OCS wind energy leasing and site assessment activities) to detect and monitor geohazards, archaeological resources, and benthic communities
- Geological and geotechnical seafloor sampling (similar to those used to support OCS wind energy leasing and site assessment activities) to assess the suitability of seafloor sediments for supporting structures (e.g., platforms, pipelines, and cables)

Detailed information on each of the specific G&G survey types and descriptions can be found in Appendix F of *Gulf of Mexico OCS Proposed Geological and Geophysical Activities: Western, Central, and Eastern Planning Areas; Final Programmatic Environmental Impact Statement* (BOEM 2017).

There are currently no G&G permits under BOEM review for areas offshore of the northeast Atlantic states; however, areas under consideration for G&G surveys are located in federal waters offshore from Delaware to Florida (BOEM 2021b).

Eight LNG ports are located on the East Coast of the United States. Table E-6 lists existing, approved, and proposed LNG ports on the East Coast of the United States that provide (or may in the future provide) services such as natural gas export, natural gas supply to the interstate pipeline system or local distribution companies, or storage of LNG for periods of peak demand, or production of LNG for fuel and industrial use (FERC 2021).

**Table E-6. Liquid Natural Gas Terminals Located in the Northeastern United States**

| Terminal Name | Type | Company | Jurisdiction | Distance from Project (approximate) | Status |
|---|---|---|---|---|---|
| Everett, MA | Import terminal | GDF SUEZ—DOMAC | FERC | 90 miles north | Existing |
| Offshore Boston, MA | Import terminal | GDF SUEZ – Neptune LNG | U.S. Department of Transportation Maritime Administration (MARAD)/USCG | 100 miles north | Existing |
| Offshore Boston, MA | Import terminal, authorized to re-export delivered LNG | Excelerate Energy—Northeast Gateway | MARAD/USCG | 95 miles north | Existing |
| Cove Point, MD (Chesapeake Bay) | Import terminal | Dominion—Cove Point LNG | FERC | 340 miles southwest | Existing |
| Cove Point, MD (Chesapeake Bay) | Export terminal | Dominion—Cove Point LNG | FERC | 340 miles southwest | Existing |
| Elba Island, GA (Savannah River) | Import terminal | El Paso—Southern LNG | FERC | 835 miles southwest | Existing |
| Elba Island, GA (Savannah River) | Export terminal | Southern LNG Company | FERC | 835 miles southwest | Existing |
| Jacksonville, FL | Export terminal | Eagle LNG Partners | FERC | 960 miles southwest | Approved |

Source: FERC (2021)

## Onshore Development Activities

Onshore development activities that may contribute to impacts from planned activities include visible infrastructure such as onshore wind turbines and cell towers, port development, and other energy projects such as transmission and pipeline projects. Coastal development projects permitted through regional planning commissions and towns may also contribute to impacts from planned activities. These may include residential, commercial, and industrial developments spurred by population growth in the region (Table E-7).

**Table E-7. Existing, Approved, and Proposed Onshore Development Activities**

| Type | Description |
|---|---|
| Local planning documents | • Suffolk County Master Plan (Suffolk County 2015)<br>• A City Master Plan: New Bedford 2020 (City of New Bedford 2010)<br>• Town of North Kingstown Comprehensive Plan Update 2008 (Town of North Kingstown 2008)<br>• Washington County Transfer of Development Rights (TDR) Study (Washington County Regional Planning Council 2012)<br>• North Kingstown Comprehensive Plan Re-Write 2019 (Interface Studio 2019) |
| Onshore wind projects | • According to the U.S. Geological Survey (USGS), there are nine onshore wind projects located within the 41-mile viewshed of the project (USGS 2018). |
| Communications towers | • There are numerous communications towers located in Suffolk County, on offshore islands, and within the viewshed of the proposed Project components. Within the recreation/tourism geographic analysis area, there are 864 communications towers, 10 of which exceed the Federal Aviation Administration (FAA) height limit for marking/lighting requirements (FAA 2016).<br>• The East Hampton Town Board is replacing its aging 800-megahertz frequency emergency communication system tower to a 700-megahertz system with updated equipment. This will require the replacement of a 150-foot communication tower with a 300-foot lattice tower and the raising of a 55-foot monopole to 85 feet. This upgrade also requires replacing antennas at towers near the East Hampton Airport in Wainscott, at the Amagansett firehouse, and at the East Hampton Town Hall complex (Chinese 2018). |
| Development projects | • As a part of New York State's $100 billion infrastructure project, $5.6 billion will go to transform the Long Island Railroad (LIRR) to improve system connectivity. Within Suffolk County, the following stations will receive funds for upgrades: Brentwood, Deer Park, East Hampton, Northport, Ronkonkoma, Stony Brook, Port Jefferson, and Wyandanch. The East Hampton historic LIRR station will undergo upgrades and modernizations (Metropolitan Transit Authority 2017; Governor's Office 2017a). Additional plans for transit-oriented design (TOD) and highway improvements are planned in Suffolk County in state and county planning documents.<br>• The Division of Statewide Planning, Rhode Island Department of Transportation, and Rhode Island Public Transit Authority prepared the Rhode Island State Transportation Improvement Program (STIP) for the Federal Fiscal Year (FFY) 2022-2023 for the adoption by the State Planning Council (State of Rhode Island 2021).<br>• Fire Island Inlet to Montauk Point (FIMP) Project is a $1.2 billion project by the USACE, NYDEC, and Long Island, NY, municipalities to engage in inlet management; beach, dune and berm construction; breach response plans; raising and retrofitting 4,400 homes; road-raising; groin modifications; and coastal process features. Within Suffolk County, portions of the Towns of Babylon, Islip, Brookhaven, Southampton, and East Hampton; 12 incorporated villages along Long Island's south shore (mainland); Fire Island National Seashore; and the Poospatuck and Shinnecock Indian Reservations will be involved in this project (USACE 2018f). |

| Type | Description |
|---|---|
| | • The USACE is working to remediate and cleanup a former defense site (former NIKE Battery PR-58 and Disaster Village Training Area) at Quonset Development Corporation in North Kingstown, RI. A feasibility study was performed from 2014 to 2016, and the final remedial investigation/feasibility study was published in 2016. Pre-design investigations, followed by remedial designs and engineering plans, and remedial action is proposed for 2021 (USACE 2018g).<br>• The Massachusetts Department of Environmental Protection (MassDEP) Bureau of Air and Waste approved National Grid's application for the construction and operation of a diesel generator and a battery electric storage system at an existing electric generating facility located at 32 Bunker Road in Nantucket, approximately 1 mile north of the coastline. The facilities are anticipated to be operational in 2019 (MassDEP 2017; Utility Dive 2018). |
| Port studies/upgrades | The USACE completed the Lake Montauk Harbor Feasibility Study in 2020. The study determined that Lake Montauk Harbor has insufficient channel and depth to support commercial fishing fleet activities. The study evaluated a range of alternative navigation improvement plans; the recommended plan consisted of deepening the existing navigation channel to -17 feet MLLW depth, creating a deposition basin immediately east of the channel at a width of 100 feet, and placing dredged material on the shoreline west of the inlet for a distance of 3,000 feet and a width of approximately 44 feet.<br>Ports in New York, Connecticut, Rhode Island, and Massachusetts may require upgrades to support the offshore wind industry developing in the northeastern United States. Upgrades may include onshore developments or underwater improvements (such as dredging).<br>• In December 2017, NYSERDA issued an offshore wind master plan that assessed 54 distinct waterfront sites along the New York Harbor and Hudson River and 11 distinct areas with multiple small sites along the Long Island coast. Twelve waterfront areas and five distinct areas were singled out for "potential to be used or developed into facilities capable of supporting OSW projects" (Table 26; NYSERDA 2017b). Nearly all identified sites would require some level of infrastructure upgrade (from minimal to significant) depending on OSW activities intended for the site. Particular sites of interest include Red Hook-Brooklyn, South Brooklyn Marine Terminal, and the Port of Coeymans (NYSERDA 2017b). For additional information regarding specific proposed improvements to these ports, see DockNYC (2018), Capital Region Economic Development Council (2018), American Association of Port Authorities (2016), Rulison (2018), and New York City Economic Development Corporation (2018).<br>• The CPA is currently evaluating proposals from parties to develop, finance, and manage the Connecticut State Pier in New London under a long-term operating agreement (CPA 2018b). According to the Connecticut Maritime Strategy 2018 (CPA 2018a), New London is the only major port between New York and Maine that does not have vertical obstruction and offshore barriers, two factors that are critical for offshore wind turbine assembly. The document includes strategic objectives to manage and redevelop the Connecticut State Pier partially to support the offshore wind industry, which could create a dramatic increase in demand for the Connecticut State Pier and regional job growth. Redevelopment of the State Pier is considered a reasonably foreseeable activity, though specific redevelopment plans are not yet available.<br>• In Rhode Island, DWW has committed to investing approximately $40 million in improvements at the Port of Providence, the Port of Davisville at Quonset Point, and possibly other Rhode Island ports for the Revolution Wind Project (Kuffner 2018). The |

| Type | Description |
|---|---|
| | Port of Davisville has added a 150-megaton mobile harbor crane, which will enable the port to handle wind turbines and heavy equipment, and enables the Port of Davisville to participate in regional offshore wind projects (Port of Davisville 2017). Further improvements at Rhode Island ports to support the offshore wind industry are considered reasonably foreseeable.<br>• The MassCEC has identified 18 waterfront sites in Massachusetts that may be available and suitable for use by the offshore wind industry. Potential activities at these sites include manufacturing of offshore wind transmission cables, manufacture and assembly of turbine components, substation manufacturing and assembly, O&M bases, and storage of turbine components (MassCEC 2017a, 2017b, 2017c). The Draft New Bedford Port Authority Strategic Plan 2018 – 2023 contains goals related to expanding the New Bedford Marine Commerce Terminal to improve and expand services to the offshore wind industry (MassCEC 2018; Port of New Bedford 2018), but no new improvements were identified.<br>• New York State proposed port improvements include the governor's 2021 agenda—Reimagine | Rebuild | Renew—which includes upgrades to create five dedicated port facilities for offshore wind, including the following:<br>• The nation's first offshore wind tower manufacturing facility, to be built at the Port of Albany<br>• An offshore wind turbine staging facility and O&M hub to be established at the South Brooklyn Marine Terminal<br>• Increasing the use of the Port of Coeymans for cutting-edge turbine foundation manufacturing<br>• Buttressing ongoing O&M out of Port Jefferson and Port of Montauk Harbor in Long Island |

# APPENDIX E1

## Description and Screening of Relevant Offshore Wind and Non–Offshore Wind Impact-Producing Factors and Negligible Impact Determinations

# Contents

# Tables

# Introduction

The Bureau of Ocean Energy Management (BOEM) developed the tables in Appendix E1 for each resource category based on the 2019 study titled *National Environmental Policy Act Documentation for Impact-Producing Factors in the Offshore Wind Cumulative Impacts Scenario on the North Atlantic Outer Continental Shelf* (BOEM 2019). The next page provides an overview table of the impact-producing factors (IPFs) considered for each resource in the environmental impact statement (EIS).

Tables E1-1 to E2-21 provide an analysis of the relevant ongoing and future non–offshore wind (OSW) activities by IPF for each resource, as well as a reference to where in the Revolution Wind Farm and Revolution Export Cable Project EIS each of those IPFs is analyzed in relation to future OSW activities and the Proposed Action and alternatives, if applicable. Some IPFs were determined either not applicable or to have negligible impacts and therefore do not warrant detailed analysis in the EIS pursuant to 40 Code of Federal Regulations (CFR) 1502.15. In these cases, IPF analysis is solely provided in Tables E1-1 to E2-21.

A full list of abbreviations is provided in the EIS's Abbreviations section. Please refer to this section for abbreviations used in the tables in this appendix.

# Air Quality

**Table E1-1. Summary of Activities and the Associated Impact-Producing Factors for Air Quality**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/ hazmat | Accidental releases of air toxics or HAPS are due to potential chemical spills. Ongoing releases occur in low frequencies. These could lead to short-term periods of toxic pollutant emissions through surface evaporation. According to the U.S. Department of Energy, 31,000 barrels of petroleum are spilled into U.S. waters from vessels and pipelines in a typical year. Approximately 40.5 million barrels of oil were lost as a result of tanker incidents from 1970 to 2009, according to International Tanker Owners Pollution Federation Limited (2021), which collects data on oil spills from tankers and other sources. From 1990 to1999, the average annual input to the coastal Northeast was 220,000 barrels of petroleum and offshore it was less than 70,000 barrels.<br>Approximately 253,000 gallons of coolants, oils and lubricants, and fuel is estimated to be stored within WTG foundations and the OSS within the GAA for existing and permitted OSW COP projects. All OSW projects are required to comply with regulatory requirements related to the prevention and control of accidental spills administered by the USCG and BSEE. | Accidental releases of air toxics or HAPS would be due to potential chemical spills. Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. These could lead to short-term periods of toxic pollutant emissions through evaporation. Air quality impacts would be short term and limited to the local area at and around the accidental release location. | Air quality impacts associated with accidental spills from other reasonably foreseeable projects could also occur; however, releases would be short term, localized, and generally small in volume and would not contribute to air quality in measurable amounts. Therefore, impacts to air quality would be **negligible** adverse. See Table E1-4 for a quantitative analysis of these risks. | **Offshore:** The Proposed Action and Alternatives C through F would result in air quality impacts from air emissions associated with accidental spills during construction and installation. Releases would be short term, localized, and generally small in volume and would not contribute to air quality in measurable amounts. Construction under Alternatives C through F could result in a reduced risk of inadvertent spills due to the reduced number of installed WTGs, resulting in a potential decrease in Project-related spill emissions. However, impacts to air quality under the Proposed Action and Alternatives C through F would still be **negligible** adverse.<br>Once the RWF has been constructed, spills are unlikely. Air quality impacts associated with any accidental spills would be short term, localized, and generally small in volume and would not contribute to air quality in measurable amounts. Alternatives C through F would result in O&M and decommissioning impacts to air quality at quantities and durations similar to, or slightly reduced from, the Proposed Action. However, impacts to air quality under the Proposed Action and Alternatives C through F would be **negligible** adverse.<br>BOEM estimates that the Proposed Action and Alternatives C through F would result in up to an 11% incremental increase in total chemical usage over the No Action Alternative in the water quality GAA. However, with the implementation of EPMs and compliance with regulations, the incremental additional effects of accidental releases from the Proposed Action would not contribute appreciably to overall impacts on air quality. Project-related accidental spills or discharges, including those associated with vessel allisions or collisions, associated with Alternatives C through F would result in air quality impacts at quantities and durations similar to, or slightly reduced from, the | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, construction and installation, O&M, and cumulative impacts would be **negligible** adverse. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | Proposed Action. Therefore, when combined with past, present, and reasonably foreseeable projects, the Proposed Action and Alternatives C through F would result in **negligible** adverse cumulative impacts to air quality due to accidental releases. | |
| | | | | **Onshore:** Inadvertent spills in onshore waters during construction, such as the release of fuels and oils from vehicles or infrastructure, which would disperse rapidly, would be classified as routine and would be localized, short term, and minor (BOEM 2015). Therefore, **negligible** adverse impacts to air quality from onshore spills are anticipated from the Proposed Action during construction and installation and O&M. The Proposed Action when combined with past, present, and other reasonably foreseeable projects would also result in short-term and **negligible** adverse cumulative impacts on air quality.<br>Alternatives C through F would not impact onshore activities; therefore, impacts would be the same as those described for the Proposed Action: **negligible** adverse. | **Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, construction and installation, O&M, and cumulative impacts would be **negligible** adverse. |
| Air emissions: Construction and decommissioning | Air emissions originate from combustion engines and electric power generated by burning fuel. These activities are regulated under the CAA to meet set standards. Air quality has generally improved over the last 35 years; however, some areas in the Northeast have experienced a decline in air quality over the last 2 years. Some areas of the Atlantic Coast remain in nonattainment for $O_3$, with the source of this pollution from power generation. Many of these states have made commitments toward cleaner energy goals to improve this, and OSW is part of these goals. Primary processes and activities that could affect the air quality impacts are expansions and modifications to existing fossil fuel power plants, onshore and offshore activities involving renewable energy facilities, and various construction activities.<br>Construction of permitted OSW projects in the GAA is estimated to generate tons of 1,451 $NO_X$, 33 tons of $SO_2$, 49 tons of $PM_{10}$, and 97,026 tons of $CO_2$. Operation of permitted and built OSW projects in the GAA | The largest air quality impacts over the next 35 years would occur during the construction phase of any one project; however, projects would be required to comply with the CAA. During the limited construction and decommissioning phases, emissions could occur that are above de minimis thresholds and would require offsets and mitigation. Primary emission sources would be due to increased commercial vehicular traffic, air traffic, public vehicular traffic, and combustion emissions from construction equipment as well as fugitive emissions from construction-generated dust. As projects come online, power generation emissions overall would decline, and the industry as a whole would have a net benefit on air quality. | See Section 3.4.2.2.2 for analysis. | See Section 3.4.2.3 and Section 3.4.2.1, Table 3.4-5 for analysis. | See Section 3.4.2.1, Table 3.4-5 for analysis. |
| Air emissions: O&M | | Activities associated with O&M of onshore wind projects would have a proportionally very small contribution to emissions compared to construction and decommissioning activities over the next 35 years. Emissions would largely be due to commercial vehicular traffic and operation of | See Section 3.4.2.2.2 for analysis. | See Section 3.4.2.3 and Section 3.4.2.1, Table 3.4-5 for analysis. | See Section 3.4.2.1, Table 3.4-5 for analysis. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | is estimated to generate 303 tons of $NO_X$, 2 tons of $SO_2$, 11 tons of $PM_{10}$, and 20,466 tons of $CO_2$. This volume represents a negligible increase to county emissions; additionally, only a portion of the generated emissions would actually reach nearby counties and would depend on wind conditions at the time the emissions are generated. | emergency diesel generators. Such activity would result in short-term, intermittent, and widely dispersed emissions and small air quality impacts. | | | |
| Air emissions: Power generation emissions reductions | | Many Atlantic states have committed to clean energy goals, with OSW playing a large role. Other reductions include transitioning to onshore wind and solar.<br>The No Action Alternative without implementation of other future OSW projects could result in increased air quality impacts regionally due to the need to construct and operate new energy generation facilities to meet future power demands. Unless substituted by other, non-OSW sources, these facilities could consist of new natural gas–fired power plants or coal-fired, oil-fired, or clean coal–fired plants. These types of facilities would likely have larger and continuous emissions and result in greater regional-scale impacts on air quality. | See Section 3.4.2.2.2 for analysis. | See Section 3.4.2.3 and Section 3.4.2.1, Table 3.4-5 for analysis. | See Section 3.4.2.1, Table 3.4-5 for analysis. |
| Climate change | Constructed and permitted OSW projects would produce GHG emissions (nearly all $CO_2$) that can contribute to climate change; however, these contributions would be minuscule compared to aggregate global emissions. $CO_2$ is relatively stable in the atmosphere and generally mixed uniformly throughout the troposphere and stratosphere. Hence, the impact of GHG emissions does not depend upon the source location. Increasing energy production from OSW projects would likely decrease GHG emissions by replacing energy from fossil fuels. | Development of future onshore wind projects would produce a small overall increase in GHG emissions over the next 35 years. However, these contributions would be very small compared to the aggregate global emissions. The impact on climate change from these activities would be very small.<br>As more projects come online, some reduction in GHG emissions would be expected from modifications of existing fossil fuel facilities to reduce power generation. Overall, it is anticipated that there would be no cumulative impact on global warming as a result of onshore wind project activities. | See Section 3.4.2.2.2 for analysis. | See Section 3.4.2.3 and Section 3.4.2.1, Table 3.4-5 for analysis. | See Section 3.4.2.1, Table 3.4-5 for analysis. |

* Includes all constructed and permitted COP projects that occur within the air quality GAA: Block Island, SFWF.

# Bats

**Table E1-2. Summary of Activities and the Associated Impact-Producing Factors for Bats**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Noise: Pile driving | Noise from pile driving associated with permitted OSW COP projects is occurring during installation of foundations for offshore structures. Noise from pile driving also occurs | Similar to ongoing activities, noise associated with pile-driving activities would be limited to nearshore waters, and these high-intensity but low-exposure risks would not be expected | See Section 3.5.2.2.2 for analysis. | See Section 3.5.2.3 and Section 3.5.2.1, Table 3.5-1 for analysis during offshore activities. | See Section 3.5.2.1, Table 3.5-1 for analysis during offshore activities. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded and would result in high-intensity, low-exposure-level long-term but localized intermittent risk to bats in nearshore waters. Direct impacts are not expected to occur as recent research has shown that bats could be less sensitive to temporary threshold shifts than other terrestrial mammals (Simmons et al. 2016). Indirect impacts (i.e., displacement from potentially suitable habitats) could occur as a result of construction activities, which could generate noise sufficient to cause avoidance behavior (Schaub et al. 2008). Construction activity would be temporary and highly localized.<br>No pile-driving noise is anticipated for built OSW COP projects in the GAA. | to result in direct impacts. Some indirect impacts (i.e., displacement from potentially suitable foraging habitats) could occur as a result of construction activities, which could generate noise sufficient to cause avoidance behavior (Schaub et al. 2008). Construction activity would be temporary and highly localized, and no population-level effects would be expected. | | | |
| Noise: Onshore Construction | Noise from onshore construction associated with permitted OSW COP projects is occurring during installation of various project components (cables, substation etc.). Other onshore construction occurs regularly for generic infrastructure projects in the bats GAA. There is a potential for displacement caused by equipment if construction occurs at night (Schaub et al. 2008). Any displacement would only be temporary. No individual or population-level impacts would be expected. Some bats roosting in the vicinity of construction activities could be disturbed during construction but would be expected to move to a different roost farther from construction noise. This behavior would not be expected to result in any impacts as frequent roost switching is a common component of a bat's life history (Hann et al. 2017; Whitaker 1998).<br>No onshore construction noise is anticipated for built OSW COP projects in the GAA. | Onshore construction is expected to continue at current trends. Some behavioral responses and avoidance of construction areas could occur (Schaub et al. 2008). However, no injury or mortality would be expected. | See Section 3.5.2.2.2 for analysis. | See Section 3.5.2.3 and Section 3.5.2.1, Table 3.5-1 for analysis during onshore activities. | See Section 3.5.2.1, Table 3.5-1 for analysis during onshore activities. |
| Presence of structures: Migration disturbances | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. There could also be a few non-OSW structures scattered throughout the offshore bats GAA, such as navigation and weather buoys and light towers (NOAA 2020a). Migrating bats can easily fly around or over these sparsely distributed structures, and no | The infrequent installation of future new structures in the marine environment of the next 35 years is expected to continue. As described under Ongoing Activities, these structures would not be expected to cause disturbance to migrating tree bats in the marine environment. | See Section 3.5.2.2.2 for analysis. | See Section 3.5.2.3 and Section 3.5.2.1, Table 3.5-1 for analysis. | See Section 3.5.2.1, Table 3.5-1 for analysis. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | migration disturbance would be expected. Bat use of offshore areas is very limited and generally restricted to spring and fall migration. Very few bats would be expected to encounter structures on the OCS, and no population-level effects would be expected. | | | | |
| Presence of structures: Turbine strikes | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. There could also be a few non-OSW structures in the offshore bats GAA, such as navigation and weather buoys, turbines, and light towers (NOAA 2020a). Migrating tree bats can easily fly around or over these sparsely distributed structures, and no strikes would be expected. | The infrequent installation of future new structures in the marine environment of the next 35 years is expected to continue. As described under Ongoing Activities, these structures would not be expected to result in increased collision risk to migrating tree bats in the marine environment. | See Section 3.5.2.2.2 for analysis. | See Section 3.5.2.3 and Section 3.5.2.1, Table 3.5-1 for analysis. | See Section 3.5.2.1, Table 3.5-1 for analysis. |
| New cable emplacement/maintenance | Constructed and permitted OSW COP projects are introducing new onshore cable in the GAA. Other non-OSW cable emplacement and maintenance activities are expected to continue to follow current trends. Potential direct effects on individuals could occur if these activities include tree removal when bats are potentially present. Injury or mortality could occur if trees being removed are occupied by bats at the time of removal. While there is some potential for indirect impacts associated with habitat loss, no individual or population-level effects would be expected. | Future non-OSW development would continue to occur at the current rate. This development has the potential to result in habitat loss and could result in injury or mortality of individuals. | See Section 3.5.2.2.2 for analysis. | See Section 3.5.2.3 and Section 3.5.2.1, Table 3.5-1 for analysis during onshore activities. | See Section 3.5.2.1, Table 3.5-1 for analysis during onshore activities. |
| Light: Vessels | Nighttime vessel activity associated with permitted and built OSW COP projects is occurring during installation and O&M of various project components (cables, substation etc.). Ocean vessels have an array of lights, including navigational lights, deck lights, and interior lights. Bats could demonstrate attraction to or avoidance of construction vessels installing offshore facilities, particularly if insects (i.e., prey) are drawn to the lights of the vessels. The impact is localized and temporary. This attraction would not be expected to result in an increased risk of collision with vessels. Population-level impacts would not be expected. | No future activities were identified within the bats GAA other than ongoing activities. | See Section 3.5.2.2.2 for analysis. | See Section 3.5.2.3 and Section 3.5.2.1, Table 3.5-1 for analysis. | See Section 3.5.2.1, Table 3.5-1 for analysis. |
| Light: Structures | Constructed and permitted OSW COP projects are introducing 83 lighted structures into the | Light from onshore structures is expected to gradually increase in proportion with human | See Section 3.5.2.2.2 for analysis. | See Section 3.5.2.3 and Section 3.5.2.1, Table 3.5-1 for analysis. | See Section 3.5.2.1, Table 3.5-1 for analysis. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | GAA. Buoys, towers, and onshore structures with lights could also attract bats. Onshore structures like houses and ports emit a great deal more light than offshore buoys and towers. This attraction has the potential to result in an increased risk of collision with lighted structures (Hüppop et al. 2006). Light from structures is widespread and permanent near the coast but minimal offshore. | population growth along the coast. This increase is expected to be widespread and permanent near the coast but minimal offshore. | | | |
| Climate change: Warming and sea level rise, storm severity/frequency | Storms during breeding and roosting season could reduce productivity and increase mortality. Intensity of this impact is speculative. | No future activities were identified within the bats GAA other than ongoing activities. | | Climate change, including increased storm severity/frequency and increased disease frequency, could impact bats. However, the intensity and extent of these potential impacts are speculative at this time; therefore, climate change is not discussed further in the context of potential impacts to bats. | Same as the Proposed Action and Alternatives C through F. |
| Climate change: Warming and sea level rise, increased disease frequency | Disease can weaken, lower reproductive output, and/or kill individuals. Some tropical diseases would move northward. Extent and intensity of this impact is highly speculative. | No future activities were identified within the bats GAA other than ongoing activities. | | Climate change, including increased storm severity/frequency and increased disease frequency, could impact bats. However, the intensity and extent of these potential impacts are speculative at this time; therefore, climate change is not discussed further in the context of potential impacts to bats. | Same as the Proposed Action and Alternatives C through F. |

* Includes all constructed and permitted COP projects that occur within the bats GAA: Block Island, SFWF, Vineyard Wind 1, Coastal Virginia Offshore Wind.

## Birds

**Table E1-3. Summary of Activities and the Associated Impact-Producing Factors for Birds**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/hazmat | Constructed and permitted OSW COP projects can accidentally release fuel, oils, or other hazardous materials in the GAA. See Table E1-4 for a quantitative analysis of these risks. Ongoing releases are frequent/chronic. Ingestion of hydrocarbons can lead to morbidity and mortality due to decreased hematological function, dehydration, drowning, hypothermia, starvation, and weight loss (Briggs et al. 1997; Haney et al. 2017; Paruk et al. 2016). Additionally, even small exposures that result in feather oiling can lead to sublethal effects that include | Gradually increasing vessel traffic over the next 35 years would increase the potential risk of accidental releases and associated impacts, including mortality, decreased fitness, and health effects on individuals. Impacts are unlikely to affect populations. | See Section 3.7.2.2.2 for analysis. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis. | See Section 3.7.2.1, Table 3.7-1 for analysis. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | changes in flight efficiencies and result in increased energy expenditure during daily and seasonal activities, including chick provisioning, commuting, courtship, foraging, long-distance migration, predator evasion, and territory defense (Maggini et al. 2017). These impacts rarely result in population-level impacts.<br>All vessels would comply with USCG requirements and BSEE regulations for the prevention and control of oil and fuel spills. | | | | |
| Accidental releases: Trash and debris | Constructed and permitted OSW COP projects can potentially generate operational waste, including bilge and ballast water, sanitary and domestic wastes, and trash and debris in the GAA. Trash and debris are also accidentally discharged through onshore sources; fisheries use; dredged material ocean disposal; marine minerals extraction; marine transportation, navigation, and traffic; survey activities; and cable, line, and pipeline laying on an ongoing basis. In a study from 2010, students at sea collected more than 520,000 bits of plastic debris per square mile. In addition, many fragments come from consumer products blown out of landfills or tossed out as litter. (Law et al. 2010). Birds could accidentally ingest trash mistaken for prey. Mortality is typically a result of blockages caused by both hard and soft plastic debris (Roman et al. 2019).<br>All vessels would adhere to federal, state, and local regulations regarding disposal of solid and liquid wastes. | As population and vessel traffic increase gradually over the next 35 years, accidental release of trash and debris could increase. This could result in increased injury or mortality of individuals. However, there does not appear to be evidence that the volumes and extents would have any impact on bird populations. | See Section 3.7.2.2.2 for analysis. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis. | See Section 3.7.2.1, Table 3.7-1 for analysis. |
| Light: Vessels | Nighttime vessel activity associated with permitted and built OSW COP projects is occurring during installation and O&M of various project components (cables, substation etc.). Ocean vessels have an array of lights, including navigational lights, deck lights, and interior lights. Such lights can attract some birds. The impact is localized and temporary. This attraction would not be expected to result in an increased risk of collision with vessels. Population-level impacts would not be expected. | Gradually increasing vessel traffic over the next 35 years would increase the potential for bird and vessel interactions. While birds could be attracted to vessel lights, this attraction would not be expected to result in increased risk of collision with vessels. No population-level impacts would be expected. | See Section 3.7.2.2.2 for analysis during offshore activities. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. | See Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Light: Structures | Constructed and permitted OSW COP projects are introducing 83 lighted structures into the GAA. Buoys, towers, and onshore structures with lights can also attract birds. Onshore structures like houses and ports emit a great deal more light than offshore buoys and towers. This attraction has the potential to result in an increased risk of collision with lighted structures (Hüppop et al. 2006). Light from structures is widespread and permanent near the coast but minimal offshore. | Light from onshore structures is expected to gradually increase in proportion with human population growth along the coast. This increase is expected to be widespread and permanent near the coast but minimal offshore. | See Section 3.7.2.2.2 for analysis. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis. | See Section 3.7.2.1, Table 3.7-1 for analysis. |
| New cable emplacement/ maintenance | Constructed and permitted OSW COP projects are introducing an estimated 498 miles of new offshore cable in the GAA. Other non-OSW cable emplacement and maintenance activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances would be temporary and generally limited to the emplacement corridor. Infrequent cable maintenance activities disturb the seafloor and cause temporary increases in suspended sediment; these disturbances would be temporary and limited to the emplacement corridor. Suspended sediment could impair the vision of diving birds that are foraging in the water column (Cook and Burton 2010). However, given the localized nature of the potential impacts, individuals would be expected to successfully forage in nearby areas not affected by increased sedimentation, and no biologically significant impacts on individuals or populations would be expected. | Future new cables would occasionally disturb the seafloor and cause temporary increases in suspended sediment, resulting in localized, short-term impacts. Impacts would be temporary and localized, with no biologically significant impacts on individuals or populations. | See Section 3.7.2.2.2 for analysis. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis. | See Section 3.7.2.1, Table 3.7-1 for analysis. |
| Noise: Aircraft | Aircraft routinely travel in the GAA for birds. With the possible exception of rescue operations and survey aircraft, no ongoing aircraft flights would occur at altitudes that would elicit a response from birds. If flights are at a sufficiently low altitude, birds could flush, resulting in nonbiologically significant increased energy expenditure. Disturbance, if any, would be localized and temporary, and impacts would be expected to dissipate once the aircraft has left the area. | Aircraft noise is likely to continue to increase as commercial air traffic increases; however, very few flights would be expected to be at a sufficiently low altitude to elicit a response from birds. If flights are at a sufficiently low altitude, birds could flush, resulting in nonbiologically significant increased energy expenditure. Disturbance, if any, would be localized and temporary and impacts would be expected to dissipate once the aircraft has left the area. | See Section 3.7.2.2.2 for analysis. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis. | See Section 3.7.2.1, Table 3.7-1 for analysis. |
| Noise: G&G | Noise from G&G surveys associated with permitted OSW COP projects may occur in the GAA. Infrequent site characterization surveys and scientific surveys produce high- | Same as ongoing activities, with the addition of possible future oil and gas surveys. | See Section 3.7.2.2.2 for analysis. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis. | See Section 3.7.2.1, Table 3.7-1 for analysis. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | intensity impulsive noise around sites of investigation. These activities could result in diving birds leaving the local area. Non-diving birds would be unaffected. Any displacement would only be temporary during non-migratory periods, but impacts could be greater if displacement were to occur in preferred feeding areas during seasonal migration periods. | | | | |
| Noise: Pile driving | Noise from pile driving associated with permitted OSW COP projects is occurring during installation of foundations for offshore structures. Noise from pile driving also occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water could result in intermittent, temporary, localized impacts on diving birds due to displacement from foraging areas if birds are present in the vicinity of pile-driving activity. The extent of these impacts depends on pile size, hammer energy, and local acoustic conditions. No biologically significant impacts on individuals or populations would be expected.<br>No pile-driving noise is anticipated for built OSW COP projects in the GAA. | No future activities were identified within the GAA for birds other than ongoing activities. | See Section 3.7.2.2.2 for analysis during offshore activities. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. | See Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. |
| Noise: Onshore construction | Noise from onshore construction associated with permitted OSW COP projects is occurring during installation of various project components (cables, substation etc.). Other onshore construction is routinely used in generic infrastructure projects. Equipment could cause displacement. Any displacement would only be temporary, and no individual fitness or population-level impacts would be expected.<br>No onshore construction noise is anticipated for built OSW COP projects in the GAA. | Onshore construction would continue at current trends. Some behavior responses could range from escape behavior to mild annoyance, but no individual injury or mortality would be expected. | See Section 3.7.2.2.2 for analysis during onshore activities. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis during onshore activities. | See Section 3.7.2.1, Table 3.7-1 for analysis during onshore activities. |
| Noise: Vessels | Noise from vessel activity associated with permitted and built OSW COP projects is occurring during installation and O&M of various project components (cables, substation etc.). Other ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Sub- | No future activities were identified within the GAA for birds other than ongoing activities. | See Section 3.7.2.2.2 for analysis during offshore activities. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. | See Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | surface noise from vessels could disturb diving birds foraging for prey below the surface. The consequence to birds would be similar to noise from G&G but likely less because noise levels are lower. | | | | |
| Presence of structures: Entanglement, gear loss, gear damage | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Additionally, each year, 2,551 seabirds die annually from interactions with U.S. commercial fisheries on the Atlantic (Sigourney et al. 2019). Even more die due to abandoned commercial fishing gear (nets). In addition, recreational fishing gear (hooks and lines) is periodically lost on existing buoys, pilings, hard protection, and other structures and has the potential to entangle birds. | No future activities were identified within the GAA for birds other than ongoing activities. | See Section 3.7.2.2.2 for analysis during offshore activities. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. | See Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. |
| Presence of structures: Fish aggregation | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Structures, including tower foundations, scour protection around foundations, and various hard protections atop cables, create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these objects. These impacts are local and can be short term to permanent. These fish aggregations can provide localized, short-term to permanent beneficial impacts to some bird species because they could increase prey species availability. | New cables, installed incrementally in the GAA for birds over the next 20 to 35 years would likely require hard protection atop portions of the cables (see New cable emplacement/maintenance row above). Any new towers, buoys, or piers would also create uncommon relief in a mostly flat seascape. Structure-oriented fishes could be attracted to these locations. Abundance of certain fishes could increase. These impacts are expected to be local and could be short term to permanent. These fish aggregations can provide localized short-term to permanent beneficial impacts on some bird species due to increased prey species availability. | See Section 3.7.2.2.2 for analysis during offshore activities. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. | See Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. |
| Presence of structures: Migration disturbances | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. There could also be a few non-OSW structures scattered about the offshore GAA for birds, such as navigation and weather buoys and light towers (NOAA 2020a). Migrating birds could easily fly around or over these sparsely distributed structures. | The infrequent installation of future new structures in the marine or onshore environment over the next 35 years would not be expected to result in migration disturbances. | See Section 3.7.2.2.2 for analysis during offshore activities. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. | See Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. |
| Presence of structures: Turbine strikes, displacement, and attraction | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. There could also be a few non-OSW structures in the offshore GAA for birds, such as navigation and weather buoys, turbines, and light towers (NOAA 2020a). Given the limited number of structures currently in the GAA, individual and population-level impacts | The installation of future new structures in the marine or onshore environment over the next 35 years would not be expected to result in an increase in collision risk or displacement. Some potential for attraction and opportunistic roosting exists but would be expected to be limited given the anticipated number of structures. | See Section 3.7.2.2.2 for analysis during offshore activities. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. | See Section 3.7.2.1, Table 3.7-1 for analysis during offshore activities. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | due to displacement from current foraging habitat would not be expected. Stationary structures in the offshore environment would not be expected to pose a collision risk to birds. Some birds like cormorants and gulls could be attracted to these structures and opportunistically roost on these structures. | | | | |
| Traffic | General aviation accounts for approximately two bird strikes per 100,000 flights (Dolbeer et al. 2019). Additionally, aircraft are used for scientific and academic surveys in marine environments. | Bird fatalities associated with general aviation would be expected to increase and follow the current trend in commercial air travel. Aircraft would continue to be used to conduct scientific research studies as well as wildlife monitoring and preconstruction surveys. These flights would be well below 100,000 flights, and no bird strikes would be expected to occur. | Aircraft flying at low altitudes and vehicle traffic could cause birds to flush, resulting in increased energy expenditure. Disturbance to birds, if any, would be temporary and localized, with impacts dissipating once the aircraft has left the area. General aircraft traffic accounts for approximately two bird strikes per 100,000 flights (Dolbeer et al. 2019). Because aircraft flights associated with OSW development would be minimal in comparison to baseline conditions, aircraft strikes with birds are rare. For this reason, aircraft traffic would not be expected to contribute to overall impacts on birds and as a result, BOEM expects no measurable impacts to birds from aircraft traffic.<br>Planned future offshore projects, specifically wind projects, would result in increased short-term construction vessel traffic and long-term maintenance vessel traffic. Some of the vessel traffic from planned future projects would use designated shipping channels. Vessel traffic could cause seabirds to flush, resulting in temporary habitat loss (Schwemmer et al. 2011). Avoidance of shipping channels could result in long-term habitat loss and fragmentation; however, these adverse impacts would be short-term **negligible** as birds would become habituated to channeled traffic. | **Offshore:** Helicopters could be used for crew changes and construction support during installation of the WTGs; however, their use would be infrequent and used during foundation construction (see COP Appendix T [Tech Environmental 2023]). Vessel traffic associated with construction activities could flush birds in the path of vessels, causing temporary displacement from the area; however, impacts would be temporary and similar to baseline conditions because vessel traffic already occurs, resulting in similar temporary displacement of birds in the GAA (Stantec 2018). The expected adverse impacts of aircraft and vessel traffic associated with each alternative alone would not increase the impacts of this IPF beyond the impacts described under the No Action Alternative. Alternatives C through F would reduce the number of WTGs installed, potentially resulting in a reduced number of helicopter trips and vessel traffic required during construction. However, no measurable change from Proposed Action construction impacts to birds from this IPF is anticipated. Therefore, impacts under the Proposed Action and Alternatives C through F are expected to be short term **negligible** adverse.<br>A hoist-equipped helicopter could be used to support O&M of the RWF; however, helicopter use would be infrequent (see COP Appendix T [Tech Environmental 2023]). Increases in vessel traffic during maintenance activities would be limited and infrequent. The expected adverse impacts to birds from aircraft and vessel traffic associated with the Proposed Action and Alternatives C through F alone would not increase the impacts of this IPF beyond the impacts described under the No Action Alternative: short term **negligible** adverse. | Similar impacts to the Proposed Action and Alternatives C through F. Therefore, construction and installation, O&M, and cumulative impacts would be **negligible** adverse. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/ Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | Aircraft flights associated with Project activities would be infrequent, and aircraft strikes with birds would be rare. Aircraft flights associated with other past, present, and reasonably foreseeable activities passing through the Lease Area would be minimal and infrequent. Vessel traffic could cause birds to flush, resulting in a temporary loss of habitat during construction activities associated with all Project alternatives. Impacts could be greater if avoidance and displacement of birds occur during seasonal migration periods. However, impacts would be temporary and similar to baseline conditions because vessel traffic already occurs in the GAA (Stantec 2018) and birds are habituated to regularly used shipping channels. In the context of reasonably foreseeable environmental trends, the combined aircraft and vessel traffic impacts from ongoing and planned actions, including the Proposed Action and Alternatives C through F, would be similar to the impacts under the No Action Alternative: long term **negligible** adverse. | |
| | | | | **Onshore:** Aircraft traffic would not have an onshore impact on birds. Therefore, impacts would be **negligible** adverse under all alternatives. | Similar impacts to the Proposed Action and Alternatives C through F. Therefore, impacts would be **negligible** adverse. |
| Climate change: Warming and sea level rise, storm severity/frequency, altered habitat/ecology | Increased storm frequency and severity during the breeding season can reduce productivity of bird nesting colonies and kill adults, eggs, and chicks.<br>Climate change, influenced in part by GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters over the next 30 years, influencing the distribution of bird prey resources. | No future activities were identified within the GAA for birds other than ongoing activities. | See Section 3.7.2.2.2 for analysis. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis. | See Section 3.7.2.1, Table 3.7-1 for analysis. |
| Climate change: Ocean acidification | Increasing ocean acidification could affect prey species upon which some birds feed and could lead to shifts in prey distribution and abundance. Intensity of impacts on birds is speculative. | No future activities were identified within the GAA for birds other than ongoing activities. | See Section 3.7.2.2.2 for analysis. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis. | See Section 3.7.2.1, Table 3.7-1 for analysis. |
| Climate change: Warming and sea level rise, altered migration patterns | Birds rely on cues from the weather to start migration. Wind direction and speed influence the amount of energy used during migration. For nocturnal migrants, wind | No future activities were identified within the GAA for birds other than ongoing activities. | See Section 3.7.2.2.2 for analysis. | See Section 3.7.2.3 and Section 3.7.2.1, Table 3.7-1 for analysis. | See Section 3.7.2.1, Table 3.7-1 for analysis. |

## Water Quality

No IPFs with solely negligible impacts were identified.

**Table E1-4. Summary of Activities and the Associated Impact-Producing Factors for Water Quality**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/ hazmat | Constructed and permitted OSW COP projects can accidentally release an estimated 200,000 gallons of fuel, oils, or other hazardous materials in the GAA. Accidental releases of fuels and fluids also occur during vessel usage for dredge material ocean disposal, fisheries use, marine transportation, military use, survey activities, and submarine cable, line, and pipeline laying activities. According to the Department of Energy, 31,000 barrels of petroleum are spilled into U.S. waters from vessels and pipelines in a typical year. Approximately 40.5 million barrels of oil were lost as a result of tanker incidents from 1970 to 2009, according to International Tanker Owners Pollution Federation Limited (2021), which collects data on oil spills from tankers and other sources. From 1990 to 1999, the average annual input to the coastal Northeast was 220,000 barrels of petroleum and into the offshore was < 70,000 barrels. Impacts on water quality would be expected to brief and localized from accidental releases. | Future accidental releases from offshore vessel usage, spills, and consumption would likely continue on a similar trend to ongoing activities. Impacts are unlikely to affect water quality. | See Section 3.21.2.2.2 for analysis. | See Section 3.21.2.3 and Section 3.21.2.1, Table 3.21-1 for analysis. | See Section 3.21.2.1, Table 3.21-1 for analysis. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | All vessels would comply with USCG requirements and BSEE regulations for the prevention and control of oil and fuel spills. | | | | |
| Accidental releases: Trash and debris | Constructed and permitted OSW COP projects can potentially generate operational waste, including bilge and ballast water, sanitary and domestic wastes, and trash and debris in the GAA. Trash and debris could be also accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities, and cable, line, and pipeline laying. Accidental releases of trash and debris are expected to be low probability events. BOEM assumes operator compliance with federal and international requirements for management of shipboard trash; such events also have a relatively limited spatial impact.<br>All vessels would adhere to federal, state, and local regulations regarding disposal of solid and liquid wastes. | As population and vessel traffic increase gradually over the next 35 years, accidental release of trash and debris could increase. However, there does not appear to be evidence that the volumes and extents anticipated would have any effect on water quality. | See Section 3.21.2.2.2 for analysis. | See Section 3.21.2.3 and Section 3.21.2.1, Table 3.21-1 for analysis. | See Section 3.21.2.1, Table 3.21-1 for analysis. |
| Anchoring | Constructed and permitted OSW COP projects are introducing an estimated 821 acres of anchoring in the GAA. Other non-OSW impacts from anchoring occur due to ongoing military use and survey, commercial, and recreational activities. | Impacts from anchoring could occur semiregularly over the next 35 years due to offshore military operations or survey activities. These impacts would include increased seafloor disturbance resulting in increased turbidity levels. All impacts would be localized, short term, and temporary. | See Section 3.21.2.2.2 for analysis within offshore waters. Anchoring would not impact onshore waters. | See Section 3.21.2.3 and Section 3.21.2.1, Table 3.21-1 for analysis within offshore waters. Anchoring would not impact onshore waters. | See Section 3.21.2.1, Table 3.21-1 for analysis within offshore waters. Anchoring would not impact onshore waters. |
| New cable emplacement/ maintenance | Constructed and permitted OSW COP projects are introducing an estimated 193 miles of new offshore cable in the GAA. Elevated suspended sediment concentrations can also occur under natural tidal conditions and increase during storms, trawling, and vessel propulsion. Survey activities and new cable and pipeline laying activities disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances would be short term and either be limited to the emplacement corridor or localized. | Suspension of sediments could continue to occur infrequently over the next 35 years due to survey activities and submarine cable, line, and pipeline-laying activities. Future new cables would occasionally disturb the seafloor and cause short-term increases in turbidity and minor alterations in localized currents resulting in local short-term impacts. The FCC has two pending submarine telecommunication cable applications in the North Atlantic. If the cable routes enter the water quality GAA, short-term disturbance in the form of increased suspended sediment and turbidity would be expected. | See Section 3.21.2.2.2 for analysis. | See Section 3.21.2.3 and Section 3.21.2.1, Table 3.21-1 for analysis. | See Section 3.21.2.1, Table 3.21-1 for analysis. |
| Port utilization: Expansion | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. Between 1992 and 2012, global shipping traffic also | The general trend along the coastal region from Virginia to Maine is that port activity would increase modestly over the next 35 years. Port modifications and channel- | See Section 3.21.2.2.2 for analysis. | See Section 3.21.2.3 and Section 3.21.2.1, Table 3.21-1 for analysis. | See Section 3.21.2.1, Table 3.21-1 for analysis. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from Virginia to Maine is that port activity would increase modestly. The ability of ports to receive the increase in larger ships would require port modifications, which, along with additional vessel traffic, could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and could continue to increase in the foreseeable future. | deepening activities are being undertaken to accommodate the increase in vessel traffic and deeper draft vessels that transit the Panama Canal locks. The additional traffic and larger vessels could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and could continue to increase in the foreseeable future. | | | |
| Presence of structures | Constructed and permitted OSW COP projects are introducing 17 structures into the GAA. The installation of onshore and offshore structures leads to alteration of local water currents. These disturbances would be local but, depending on the hydrologic conditions, have the potential to impact water quality through the formation of sediment plumes. | Impacts associated with the presence of structures includes temporary sediment disturbance during maintenance. This sediment suspension would lead to interim and localized impacts. | See Section 3.21.2.2.2 for analysis. | See Section 3.21.2.3 and Section 3.21.2.1, Table 3.21-1 for analysis. | See Section 3.21.2.1, Table 3.21-1 for analysis. |
| Discharges | Constructed and permitted OSW COP projects can potentially generate operational waste, including bilge and ballast water, sanitary and domestic wastes, and trash and debris in the GAA. Discharges impact water quality by introducing nutrients, chemicals, and sediments to the water. There are regulatory requirements related to prevention and control of discharges, the prevention and control of accidental spills, and the prevention and control of nonindigenous species. | Increased coastal development is causing increased nutrient pollution in communities. In addition, ocean disposal activity in the North Atlantic and Mid-Atlantic is expected to gradually decrease or remain stable. Impacts of ocean disposal on water quality are minimized because the EPA has established dredge spoil criteria and regulate the disposal permits issued by the USACE.<br>The impact on water quality from sediment suspension during these future activities would be short term and localized. | See Section 3.21.2.2.2 for analysis. | See Section 3.21.2.3 and Section 3.21.2.1, Table 3.21-1 for analysis. | See Section 3.21.2.1, Table 3.21-1 for analysis. |

* Includes two constructed and permitted COP projects that occur within the water quality GAA: Block Island, SFWF.

# Coastal Habitats and Fauna

**Table E2-1**. **Summary of Activities and the Associated Impact-Producing Factors for Coastal Habitats and Fauna**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| New cable emplacement/ maintenance | Onshore buried transmission cables are present in the area near the Project onshore and offshore improvements. Onshore activities would only occur where permitted by local land use authorities, which would avoid long-term land use conflicts. Continual development of residential, commercial, industrial, solar, transmission, gas pipeline, onshore wind turbine, transportation infrastructure, sewer infrastructure, and cell tower projects could permanently convert various areas. | No known proposed onshore structures are reasonably foreseeable and proposed to be located in the GAA for coastal habitats and fauna. | A small amount of infrequent construction impacts associated with onshore power infrastructure would be required over the next 6 to 10 years to tie future OSW energy projects to the electric grid. Typically, this would require only small, if any, amounts of coastal habitat removal and would likely occur in previously disturbed areas. Habitat loss occurs when an area supporting wildlife is converted to non-habitat that lacks the natural resources to support occupancy for any species, such as paved areas. Short-term and temporary impacts associated with habitat loss or avoidance during construction could occur, and injury or mortality of individuals could occur. For this reason, land disturbance associated with onshore construction activities would have a **negligible** contribution to overall adverse impacts on coastal habitats and fauna. | **Onshore**: During construction of the onshore transmission cable and associated activities within the landfall work area, land disturbance could result in small temporary impacts (e.g., displacement and potential injury and/or mortality of individuals) on coastal fauna. Land disturbance and subsequent habitat removal or alteration could result from the RWEC connection to the landfall work area and construction of the onshore transmission cable. Potential indirect impacts to coastal habitats would include the spread of invasive species, reduction in habitat quality, and displacement of wildlife and resources based on changes to habitat conditions.<br>The potential for onshore construction and habitat alteration to significantly affect coastal habitat is limited because the landfall work area consists of areas of predominately human-made shoreline and grassland/shrubland areas as a result of previous human activity. Habitat conversion is not a factor for developed areas (e.g., existing buildings, mowed lawns, parking lots, roads) within the landfall envelope. The construction period for the onshore facilities would occur over approximately 18 months, and the infrastructure at the landfall work area would be placed underground when completed. HDD would be employed to connect the RWEC and the landfall work area. This would limit or completely avoid direct impacts to the human-made shoreline and ruderal grassland/shrubland because the RWEC would be installed under these resources. The temporary onshore construction work area for the HDD operations would likely be situated within a previously developed area (e.g., an existing parking lot) and would not impact the human-made shoreline and/or the ruderal grassland/shrubland. However, if these habitat types are disturbed, these impacts would be short term because the area would be reseeded to re-establish previous conditions. The human-made shoreline does not support | Similar impacts to the Proposed Action and Alternatives C through F. Therefore, construction and installation, O&M, and cumulative impacts would be **negligible** adverse. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | any vegetative growth. A potential indirect impact to coastal habitat from onshore construction and habitat alteration linked to construction of the landfall work area is habitat degradation via the spread of invasive species. If vegetative clearing is required within the ruderal grassland/shrubland for construction of the landfall work area, then this could provide an opportunity for invasive plant species to outcompete native plants. The baseline conditions of the ruderal grassland/shrubland habitat already support a high occurrence of invasive plant species. Habitats with high levels of invasive species can degrade habitat quality for wildlife by reducing the amount of native plant material available for foraging. However, this area of undisturbed habitat is so small it is unlikely to provide a significant habitat resource to wildlife. The spread of invasive species would be managed in compliance with state and federal regulations. Impacts to coastal habitats and fauna from construction activities at the landfall work area would be considered short-term **negligible** adverse for the Proposed Action and Alternatives C through F.<br><br>As noted within the landfall work area impact assessment, wildlife species subject to direct mortality during construction of the onshore facilities are those with limited or no mobility. Onshore transmission cable installation would result in temporary ground disturbance, but permanent disturbances are not anticipated. Most of the temporary ground disturbance would be from a trench that would follow along paved roads or previously disturbed areas (e.g., parking lots) except for a small portion that intersects approximately 0.02 acre of plantation and ruderal forest.<br><br>The onshore transmission cable would be up to 1 mile long with a maximum temporary disturbance corridor of 25 feet (30 feet at splice vaults) and a maximum disturbance depth of 10 feet that would be mostly limited to established road ROWs or previously disturbed areas such as parking lots with little to no impact to adjacent coastal and terrestrial habitat. Where the onshore transmission cable would connect to the OnSS, it would be | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | installed below a proposed access driveway. Some of the alternative routes under consideration within the transmission cable envelope contain segments that would pass through undeveloped, vegetated areas. If selected, these routes would require vegetative clearing and would be maintained as managed lawn and or gravel access road to maintain access to the cable infrastructure belowground. Since these segments of the onshore transmission cable routes under consideration would be installed within previously undeveloped areas, the impacts resulting from habitat alteration and conversion would be considered long term and **negligible**. Regular O&M activities would not cause further habitat alteration or impact coastal habitats and fauna. However, when cable inspection or repairs require excavation, this nonroutine maintenance could cause limited land disturbance to create access to the infrastructure. Such occurrences are expected to be infrequent and would result in localized and short-term **negligible** adverse impacts to coastal habitats and fauna for the Proposed Action and Alternatives C through F. Decommissioning of the onshore transmission cable would have similar impacts on coastal habitats and fauna to those described for the construction phase if the underground infrastructure is removed. If the infrastructure is abandoned in place, it would not have any impacts.<br><br>Construction and installation, O&M, and decommissioning of the onshore transmission cable under all Project alternatives would incrementally contribute to the habitat conversion and habitat loss described under the No Action Alternative. Because of the small amount of affected onshore habitat, land disturbance from the Proposed Action and Alternatives C through F when added to other past, present, and reasonably foreseeable projects would result in **negligible** adverse incremental impacts to coastal habitats and fauna. | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Presence of structures | Periodic clearing of shrubs and tree saplings along existing utility ROWs causes disturbance and temporary displacement of mobile species and could cause direct injury or mortality of less mobile species, resulting in short-term impacts that are less than noticeable. Continual development of residential, commercial, industrial, solar, transmission, gas pipeline, onshore wind turbine, and cell tower projects also causes disturbance, displacement, and potential injury and/or mortality of fauna, resulting in small temporary impacts. | No future activities were identified within the GAA other than ongoing activities. | See Section 3.8.2.2.2 for analysis. | See Section 3.8.2.3 and Section 3.8.2.1, Table 3.8-2 for analysis of onshore impacts. The IPF would not impact offshore resources. | See Section 3.8.2.1, Table 3.8-2 for analysis of onshore impacts. The IPF would not impact offshore resources. |
| Noise: Onshore/offshore construction | Ongoing noise from construction occurs frequently near shores of populated areas in New England and the Mid-Atlantic region but infrequently offshore. Noise from construction near shorelines is expected to gradually increase over the next 30 years, in line with human population growth along the coast of the GAA. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. | No future activities were identified within the GAA other than ongoing activities. | Onshore construction noise has the potential to have a **negligible** adverse impact on coastal fauna. BOEM anticipates that these impacts would be temporary and highly localized. Habitat-related impacts (i.e., displacement from potentially suitable habitats) could occur as a result of construction activities. These impacts would likely be limited to temporary behavioral avoidance, and no permanent impacts would be expected. Given the temporary and localized nature of potential impacts, and the current level of development within the GAA, no individual fitness or population-level impacts would occur as a result of noise associated with onshore construction activities. | **Onshore:** Another potential indirect impact to coastal fauna during construction of the onshore facilities is displacement or avoidance behavior of individuals due to noise. The overall installation schedule for onshore facilities is expected to be approximately 1 year (see COP Section 3.2, Project Schedule). Construction would typically result in temporary increases in noise. As described in VHB’s onshore acoustic assessment (VHB 2023a), noise was evaluated based generally on the noisiest condition when the loudest construction equipment would be in operation. The primary noise sources generated during construction would be from increased traffic volumes (i.e., delivery trucks carrying construction equipment and supplies and automobiles used for daily commuting to various work sites) and HDD at the landfall work area. Sound-generating construction equipment associated with HDD operations would include a drill rig, a generator, and mud pumps. Unlike most other construction activities that can be limited to daytime hours, it is typically necessary for HDD operations to occur continuously to minimize the risk of soil settlement and equipment failures. Other noise-generating equipment used during HDD operations would include an excavator, a crane, and either an impact or vibratory sheet pile driver for site preparation. The onshore acoustic assessment (VHB 2023a) indicates that construction equipment used to support construction of the landfall work area could create sound levels that range from 56 to 101 dBA at 50 feet from the noise source. Ambient | Similar impacts to the Proposed Action and Alternatives C through F. Therefore, construction and installation, O&M, and cumulative impacts would be **negligible** adverse. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | sound measurements conducted within the GAA under existing conditions ranged from 44 to 45 dBA (Leq) at night and 49 to 50 dBA during the day (VHB 2023a).<br>Construction of the onshore transmission cable would involve different construction phases, each using noise-generating equipment such as bulldozers, backhoes, front-end loaders, aerial lifts, trenchers, compactors, concrete saws, graders, pumps, compressors, and trucks. Because the onshore transmission cable installation process would progress along the cable route during this period, the exposure to construction noise would be limited to a discrete duration at any location along the route. The onshore acoustic assessment (VHB 2023a) indicates that construction equipment used to support construction of the onshore transmission cable could create sound levels that range from 73 to 90 dBA at 50 feet from the noise source depending on the installation methodology. The sequence for construction of the OnSS and ICF would typically include clearing the site of vegetation, grading the site, installing environmental erosion controls, installing the foundations and erecting buildings for housing equipment, and restoring any disturbed areas on the site and removing environmental controls. The types of construction equipment used would generally include backhoes, cranes, refrigerator units, front-end loaders, and generators. The onshore acoustic assessment (VHB 2023a) indicates that construction equipment used to support construction of the OnSS could create sound levels that range from 80 to 85 dBA at 50 feet from the noise source.<br>Potential impacts to coastal fauna from the temporary increase in construction-generated noise could include avoidance behavior and displacement during the construction period (Brown et al. 2012). Because the construction period is temporary, noise impacts on wildlife species during construction of the onshore facilities of the Proposed Action and Alternatives C through F are expected to be temporary **negligible** adverse.<br>No impacts related to noise would be expected from operation of the onshore transmission | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | cable because the infrastructure would be underground. However, when cable inspection or repairs require excavation, this non-routine maintenance could generate equipment- and vehicle-related noise. Such occurrences are expected to be infrequent and would result in localized and short-term **negligible** adverse impacts to coastal habitats and fauna. Decommissioning of the onshore transmission cable would have similar impacts from noise on coastal habitats and fauna to those described for the construction phase if the underground infrastructure is removed. If the infrastructure is abandoned in place, it would not have any impacts.<br>O&M at the proposed OnSS and ICF would introduce new sources of sound, including transformers, shunt reactors, harmonic filters, cooling and ventilation associated with the outdoor substation equipment as well as condensers, pumps, skids, and auxiliary transformers associated with the synchronous condenser building. Operational sound from the OnSS and ICF is modeled to be 45.5 dBA (Leq) or less when measured at the nearest anthropogenic noise sensitive receivers, which would fall within the ambient sound range measured at baseline conditions (44 to 45 dBA (Leq) at night and 49 to 50 dBA during the day) (VHB 2023a), and no impacts to coastal fauna are expected.<br>Temporary noise could occasionally be generated during non-routine maintenance at all onshore facilities. Infrequent vehicle usage within the OnSS and ICF could create temporary disturbance to wildlife adjacent to the OnSS, but such disturbance would be short term, and normal wildlife activity would likely resume after the traffic ceases. Impacts from noise during decommissioning of onshore facilities would be similar to those during construction: temporary **negligible** adverse for all Project alternatives.<br>Construction, O&M, and decommissioning of the onshore facilities would also produce temporary noise that would lead to short-term negligible incremental impacts, if any, on coastal habitats and fauna. The onshore elements of the Proposed Action and | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | Alternatives C through F would be in already developed areas with existing noise disturbance where wildlife is habituated to human activity. Therefore, the cumulative impact of noise generated by the Proposed Action and Alternatives C through F on coastal habitats and fauna when combined with past, present, and reasonably foreseeable projects would be localized and short term **negligible** adverse. | |
| Climate change: Warming and sea level rise, altered habitat/ecology | Climate change, influenced in part by GHG emissions, is altering the seasonal timing and patterns of species distributions and ecological relationships, likely causing permanent changes of unknown intensity gradually over the next 35 years. | No future activities were identified within the GAA other than ongoing activities. | See Section 3.8.2.2.2 for analysis. | See Section 3.8.2.3 and Section 3.8.2.1, Table 3.8-2 for analysis of onshore impacts. The IPF would not impact offshore resources. | See Section 3.8.2.1, Table 3.8-2 for analysis of onshore impacts. The IPF would not impact offshore resources. |

* No constructed and permitted COP projects occur within the coastal habitats and fauna GAA.

## Wetlands and Non-tidal Waters

**Table E2-2. Summary of Activities and the Associated Impact-Producing Factors for Wetlands and Non-tidal Waters**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/ hazmat | Ongoing onshore construction projects that involve vehicles and equipment that use fuel, fluids, or hazardous materials could result in an accidental release. Intensity and extent would vary, depending on the size, location, and materials involved in the release. | No future activities were identified within the GAA for wetlands and non-tidal waters other than ongoing activities. | See Section 3.22.2.2.2 for analysis. | See Section 3.22.2.3 and Section 3.22.2.1, Table 3.22-2 for analysis of onshore impacts. The IPF would not impact offshore resources. | See Section 3.22.2.1, Table 3.22-2 for analysis of onshore impacts. The IPF would not impact offshore resources. |
| Accidental releases: Trash and debris | Ongoing releases of trash and debris occur from onshore sources; fisheries use; dredged material ocean disposal; marine minerals extraction; marine transportation; navigation and traffic; survey activities; and cable, line, and pipeline laying. | No future activities were identified within the GAA for wetlands and non-tidal waters other than ongoing activities. | See Section 3.22.2.2.2 for analysis. | See Section 3.22.2.3 and Section 3.22.2.1, Table 3.22-2 for analysis of onshore impacts. The IPF would not impact offshore resources. | See Section 3.22.2.1, Table 3.22-2 for analysis of onshore impacts. The IPF would not impact offshore resources. |
| Discharges | Discharges impact water quality by introducing nutrients, chemicals, and sediments to the water. There are regulatory requirements related to the prevention and control of discharges, the prevention and control of accidental spills, and the prevention and control of nonindigenous species. | Increased future coastal development has the potential to cause increased nutrient pollution in communities, approximately 80% of which is due to groundwater contamination by septic systems. In addition, ocean disposal activity in the North Atlantic is expected to gradually decrease or remain stable. Impacts of ocean disposal on water quality are minimized because the EPA has | See Section 3.22.2.2.2 for analysis. | See Section 3.22.2.3 and Section 3.22.2.1, Table 3.22-2 for analysis of onshore impacts. The IPF would not impact offshore resources. | See Section 3.22.2.1, Table 3.22-2 for analysis of onshore impacts. The IPF would not impact offshore resources. |

|---|---|---|---|---|---|
| | | established dredge spoil criteria and regulates the disposal permits issued by the USACE. | | | |
| New cable emplacement/ maintenance | No known proposed cables are reasonably foreseeable and proposed to be located in the GAA for wetlands and non-tidal waters. | Any new cable or pipeline installed in the GAA would likely require hard protection atop portions of the route. Such protection is anticipated to increase incrementally over the next 30 years. | See Section 3.22.2.2.2 for analysis. | See Section 3.22.2.3 and Section 3.22.2.1, Table 3.22-2 for analysis of onshore impacts. The IPF would not impact offshore resources. | See Section 3.22.2.1, Table 3.22-2 for analysis of onshore impacts. The IPF would not impact offshore resources. |
| Presence of structures | Ongoing development of onshore properties, especially shoreline parcels, periodically could lead to unvegetated or otherwise unstable soils. Precipitation events could potentially mobilize the soils into nearby surface waters, leading to potential erosion and sedimentation effects and subsequent increased turbidity. No known proposed structures are reasonably foreseeable and proposed to be located in the GAA for wetlands and non-tidal waters. | Impacts associated with the presence of structures includes temporary sediment disturbance during maintenance and ongoing development. This sediment suspension would lead to short-term and localized impacts. | See Section 3.22.2.2.2 for analysis. | See Section 3.22.2.3 and Section 3.22.2.1, Table 3.22-2 for analysis of onshore impacts. The IPF would not impact offshore resources. | See Section 3.22.2.1, Table 3.22-2 for analysis of onshore impacts. The IPF would not impact offshore resources. |
| Sediment deposition and burial | Ongoing cable or structure maintenance activities can infrequently disturb sediments; these disturbances are local and limited to the emplacement corridor. Precipitation events could potentially mobilize the disturbed sediments into nearby surface waters, leading to potential erosion and sedimentation effects and subsequent increased turbidity. | No future activities were identified within the GAA other than ongoing activities. | Dredge materials from future OSW activities would not be disposed of in areas with wetlands or other WOTUS within the GAA. Therefore, **negligible** adverse impacts to wetlands and non-tidal waters within the GAA are anticipated. | Dredged materials from Project activities would not be disposed of in areas with wetlands or other WOTUS. Therefore, sediment deposition and burial impacts on wetlands and non-tidal waters from construction and installation would be the same for the Proposed Action and Alternatives C through F: **negligible** adverse.<br>O&M of onshore O&M facilities could include dredging activities for the Proposed Action and Alternatives C through F; however, materials from O&M activities would not be disposed of in areas with wetlands or other WOTUS. Therefore, **negligible** adverse impacts to wetlands and non-tidal waters from sediment deposition and burial are anticipated for all Project alternatives.<br>Dredge materials from the Proposed Action and Alternatives C through F and other future OSW projects within the GAA would not be disposed of in areas with wetlands or other WOTUS. As a result, when combined with past, present, and reasonably foreseeable projects, the Proposed Action and Alternatives C through F are expected to result in **negligible** adverse impacts to wetlands and non-tidal waters. | Similar impacts to the Proposed Action and Alternatives C through F. Therefore, construction and installation impacts would be short term **negligible** adverse. O&M impacts to wetlands and non-tidal waters are anticipated to be **negligible** adverse. When combined with past, present, and reasonably foreseeable projects, Alternative G is expected to result in **negligible** adverse impacts to wetlands and non-tidal waters. |
| Climate change: Warming and sea | Climate change, influenced in part by ongoing GHG emissions, is expected to continue to | No future activities were identified within the GAA other than ongoing activities. | Impacts of climate change, including increased storm severity and frequency, are | Air pollutants could impact onshore biological resources, including wetlands and WOTUS. | Similar impacts to the Proposed Action and Alternatives C through F. Therefore, |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| level rise, altered habitat/ecology | contribute to a widespread loss of shoreline habitat from rising seas and erosion. In submerged habitats, warming is altering ecological relationships and the distributions of ecosystem engineer species, likely causing permanent changes of unknown intensity gradually over the next 3 years. | | ongoing stressors for wetlands and non-tidal waters. Future OSW projects aim to combat climate change and associated effects by reducing GHG emissions. Under the No Action Alternative, the long-term net decrease in GHG emissions from other ongoing and future OSW and other non-fossil fuel–based energy generation projects would be slightly less than with the Proposed Action. As a result, the effects to wetlands and non-tidal waters would be **negligible** to **minor** adverse, as they are anticipated to occur but have no measurable influence within the GAA. | Acidification of soils, lakes, and streams could result in changes in community structure and biodiversity within these habitats. The OCS air permitting process will require air dispersion modeling of these emissions to demonstrate compliance with the NAAQS. Specifically, EPA requires modeling of NAAQS and Class I significant impact levels for the purpose of PSD permitting for the construction and operation of Revolution Wind. Compliance with the NAAQS offshore in and near the Lease Area will be evaluated with air quality dispersion modeling through EPAs OCS permitting. Because air emissions generated during the construction and installation period would not exceed applicable air emission standards the impacts to onshore wetlands and non-tidal waters would be short-term **negligible** adverse.<br>While cumulative air emissions in the region would increase during construction, it is important to note that the Proposed Action could also contribute to a long-term net decrease in emissions by substituting some existing fossil fuel sources with a renewable source. Therefore, impacts to wetlands and non-tidal waters are anticipated to be **negligible** adverse.<br>The cumulative impacts from global climate change would be the same as those described for future OSW activities without the Proposed Action because emissions from other past, present, and reasonably foreseeable projects, in combination with air emissions generated during construction and O&M would not exceed applicable air emission standards. Thus, potential impacts to wetlands and non-tidal waters from the incremental contribution to climate change attributed to the Proposed Action when combined with past, present, and other reasonably foreseeable projects are uncertain but are anticipated to qualify as long term **negligible** adverse.<br>Alternatives C through F would have the same onshore activities and facilities as the Proposed Action; therefore, climate change impacts on wetlands and non-tidal waters | construction and installation impacts would be short term **negligible** adverse. O&M impacts to wetlands and non-tidal waters are anticipated to be **negligible** adverse. Potential impacts to wetlands and non-tidal waters from the incremental contribution to climate change attributed to the Proposed Action when combined with past, present, and other reasonably foreseeable projects are uncertain but are anticipated to qualify as long term **negligible** adverse. |

* No constructed and permitted COP projects occur within the wetlands and non-tidal waters GAA.

## Benthic Habitat and Invertebrates

**Table E2-3. Summary of Activities and the Associated Impact-Producing Factors for Benthic Habitat and Invertebrates**

| Associated IPFs: Sub-IFPs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/ hazmat | Constructed and permitted OSW COP projects can accidentally release an estimated 900,000 gallons of fuel, oils, or other hazardous materials into the invertebrates GAA. See Table E1-4 for a discussion of ongoing accidental releases. Accidental releases of hazmat occur periodically, mostly consisting of fuels, lubricating oils, and other petroleum compounds. Because most of these materials tend to float in seawater, they rarely contact benthic resources. The chemicals with potential to sink or dissolve rapidly often dilute to nontoxic levels before they affect benthic resources. The corresponding impacts on benthic resources are rarely noticeable. Impacts, including mortality and decreased fitness, are localized and temporary and rarely affect invertebrate populations.<br>All vessels would comply with USCG requirements and BSEE regulations for the prevention and control of oil and fuel spills. | Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. Impacts are unlikely to affect invertebrate populations. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Accidental releases: Invasive species | Invasive species are periodically released accidentally during ongoing activities, including the discharge of ballast water and bilge water from marine vessels. The impacts on benthic resources (e.g., competitive disadvantage, smothering) depend on many factors but can be noticeable, widespread, and permanent. | No future activities were identified within the GAA other than ongoing activities. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Accidental releases: Trash and debris | Constructed and permitted OSW COP projects can potentially generate operational waste, including bilge and ballast water, sanitary and domestic wastes, and trash and debris into the invertebrates GAA. Other ongoing releases of trash and debris occurs from onshore sources; fisheries use; dredged | No future activities were identified within the GAA other than ongoing activities. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on |

| Associated IPFs: Sub-IFPs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | material ocean disposal; marine minerals extraction; marine transportation; navigation and traffic; survey activities; and cable, line, and pipeline laying. However, there does not appear to be evidence that ongoing releases have detectable impacts on benthic resources.<br>All vessels would adhere to federal, state, and local regulations regarding disposal of solid and liquid wastes. | | | effect on benthic habitat or invertebrates and are not analyzed. | benthic habitat or invertebrates and are not analyzed. |
| Anchoring | Constructed and permitted OSW COP projects are introducing an estimated 944 acres of anchoring in the invertebrates GAA. This, combined with regular vessel anchoring related to other ongoing military, survey, commercial, and recreational activities, continues to cause temporary to permanent impacts in the immediate area where anchors and chains meet the seafloor. These impacts include increased turbidity levels and the potential for direct contact to cause injury and mortality of benthic resources as well as physical damage to their habitats. These impacts are greatest for sessile or slow-moving species (e.g., corals, sponges, and sedentary shellfish). All impacts are localized; turbidity is temporary; injury and mortality are recovered in the short term; and physical damage can be permanent if it occurs in eelgrass beds or hard-bottom habitat. | No future activities were identified within the GAA other than ongoing activities. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Bycatch | Bycatch occurs in various gillnet and trawl fisheries in New England and the Mid-Atlantic Coast, with hotspots driven by fishing intensity (Lewison et al. 2014; NMFS 2018a). | No future activities were identified within the GAA for this resource other than ongoing activities. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| EMFs | Constructed and permitted OSW COP projects can generate EMF and substrate heating effects, altering the environment for benthic invertebrates and other organisms associated with those habitats.<br>EMFs also continuously emanate from existing telecommunication and electrical power transmission cables. New cables generating EMFs are infrequently installed in | No future activities were identified within the GAA other than ongoing activities. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |

| Associated IPFs: Sub-IFPs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | the GAA. Some benthic species can detect EMFs, although EMFs do not appear to present a barrier to movement.<br>The extent of impacts (behavioral changes) is likely less than 50 feet (15.2 m) from the cable and the intensity of impacts on benthic resources is likely undetectable. | | | | |
| Light: Vessels | Nighttime vessel activity associated with permitted and built OSW COP projects is occurring during installation and O&M of various project components (cables, substation etc.). Marine vessels have an array of lights, including navigational lights and deck lights. There is little downward-focused lighting and therefore only a small fraction of the emitted light enters the water. Light can attract invertebrates, potentially affecting distributions in a highly localized area. Light could also disrupt natural cycles (e.g., spawning), possibly leading to short-term impacts. | See table cell to the left. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Light: Structures | Constructed and permitted OSW COP projects are introducing 83 lighted structures into the invertebrate GAA. Offshore buoys and towers emit light, and onshore structures, including buildings and ports, emit a great deal more on an ongoing basis. Light can attract invertebrates, potentially affecting distributions in a highly localized area. Light could also disrupt natural cycles, e.g., spawning, possibly leading to short-term impacts. Light from structures is widespread and permanent near the coast, but minimal offshore. | Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast, but minimal offshore. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| New cable emplacement/ maintenance | Constructed and permitted OSW COP projects are introducing an estimated 498 miles of new offshore cable in the GAA. This and other non-OSW cable maintenance activities infrequently disturb benthic resources and cause temporary increases in suspended sediment; these disturbances would be local and limited to the emplacement corridor. New cables are infrequently added near shore. Cable emplacement/maintenance activities injure and kill benthic resources and result in temporary to long-term habitat alterations. The intensity of impacts depends on the time (season) and place (habitat type) | Future new cables would occasionally disturb the seafloor and cause temporary increases in suspended sediment, resulting in local short-term impacts.<br>The FCC has two pending submarine telecommunication cable applications in the North Atlantic. If the cable routes enter the GAA for this resource, short-term disturbance would be expected. The intensity of impacts would depend on the time (season) and place (habitat type) where the activities would occur. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |

|---|---|---|---|---|---|
| | where the activities occur. (See also the IPFs of seafloor profile alterations and sediment deposition and burial.) | | | | |
| Noise: Aircraft | Noise from aircraft reaches the sea surface on a regular basis. However, there is not likely to be any impact of aircraft noise on benthic habitat and invertebrates, as very little of the aircraft noise propagates through the water. | Aircraft noise is likely to continue to increase as commercial air traffic increases. However, there is not likely to be any impact of aircraft noise on benthic habitat and invertebrates. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Noise: Onshore/offshore construction | Noise from onshore construction associated with permitted OSW COP projects is occurring during installation of various project components (cables, substation etc.). Other noise from construction occurs frequently in the nearshores of populated areas in New England and the Mid-Atlantic region but infrequently offshore. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. Detectable impacts of construction noise on benthic resources rarely, if ever, overlap from multiple sources. See also sub-IPF for Noise: Pile driving. | Noise from construction near shorelines is expected to gradually increase in line with human population growth along the coast of the GAA for this resource. Detectable impacts of construction noise on benthic resources would rarely, if ever, overlap from multiple sources. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Noise: G&G | Noise from G&G surveys associated with permitted OSW COP projects may occur in the invertebrate GAA. Ongoing site characterization surveys and scientific surveys produce noise around sites of investigation. These activities can disturb invertebrates in the immediate vicinity of the investigation and can cause temporary behavioral changes. The extent depends on equipment used, noise levels, and local acoustic conditions. Detectable impacts of G&G noise on benthic resources rarely, if ever, overlap from multiple sources. | Site characterization surveys, scientific surveys, and exploratory oil and gas surveys are anticipated to occur infrequently over the next 35 years. Seismic surveys used in oil and gas exploration create high-intensity impulsive noise to penetrate deep into the seafloor, potentially resulting in injury or mortality to invertebrates in a small area around each sound source and short-term stress and behavioral changes to individuals over a greater area. Site characterization surveys typically use sub-bottom profiler technologies that generate less intense sound waves more similar to common deep-water echosounders. The intensity and extent of the resulting impacts are difficult to generalize but are likely local and temporary. Detectable impacts of G&G noise on benthic resources would rarely, if ever, overlap from multiple sources. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Noise: O&M | Noise from O&M associated with built OSW COP projects may occur in the invertebrate | New or expanded marine minerals extraction and commercial fisheries could intermittently | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore |

|---|---|---|---|---|---|
| | GAA. Some invertebrates could be able to hear the continuous underwater noise of operational WTGs. As measured at the BIWF, this low-frequency noise barely exceeds ambient levels at 164 feet (50 m) from the WTG base. Based on the results of Thomsen et al. (2015), sound pressure levels would be expected to be at or below ambient levels at relatively short distances (approximately 164 feet [50 m]) from WTG foundations. These low levels of elevated noise likely have little to no impact.<br>Noise is also created by O&M of marine minerals extraction and commercial fisheries, each of which has small local impacts. | increase noise during their O&M over the next 35 years. Impacts would likely be small and local. | activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Noise: Pile driving | Noise from pile driving associated with permitted OSW COP projects is occurring during installation of foundations for offshore structures. Noise from pile driving also occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seafloor can cause injury and/or mortality to benthic resources in a small area around each pile and can cause short-term stress and behavioral changes to individuals over a greater area. Eggs, embryos, and larvae of invertebrates could also experience developmental abnormalities or mortality resulting from this noise, although thresholds of exposure are not known (Hawkins and Popper 2017; Weilgart 2018). The extent depends on pile size, hammer energy, and local acoustic conditions. | No future activities were identified within the GAA other than ongoing activities. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Noise: Cable laying/trenching | Noise from trenching/cable laying associated with permitted OSW COP projects may occur in the invertebrates GAA. Infrequent trenching activities for other pipeline and cable laying, as well as other cable burial methods, also emit noise. These disturbances are local, temporary, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension. | New or expanded submarine cables and pipelines are likely to occur in the GAA. These disturbances would be infrequent over the next 35 years, local, temporary, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |

| Associated IPFs: Sub-IFPs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Port utilization: Expansion | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance, including dredging. Port utilization is expected to increase over the next 35 years. | Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and could continue to increase in the foreseeable future. In addition, the general trend along the coast from Virginia to Maine is that port activity would increase modestly. The ability of ports to receive the increase could require port modifications, leading to local impacts.<br>Future channel-deepening activities would likely be undertaken. Existing ports have already affected benthic resources and invertebrates, and future port projects would implement BMPs to minimize impacts. Although the degree of impacts would likely be undetectable outside the immediate vicinity of the ports, adverse impacts for certain species and/or life stages could lead to impacts on benthic resources and invertebrates beyond the vicinity of the port. | **Offshore:** The development of an OSW industry on the Mid-Atlantic OCS could incentivize the expansion or improvement of regional ports to support planned and future projects. Activities like dredging and the expansion or development of new overwater structures could lead to adverse effects on coastal and estuarine benthic habitats and invertebrates or benthic resources. However, any such impacts would be outside the GAA for benthic habitat and the nature and extent of these impacts on invertebrates cannot currently be quantified as no specific port improvement activities have been proposed. Therefore, these activities would have a **negligible** adverse impact on benthic resources and invertebrates. Any future port expansion would be subject to independent NEPA analysis and regulatory approvals requiring full consideration of potential environmental effects. | **Offshore:** Several regional ports could be used during Project construction and decommissioning, including ports in Baltimore, MD; New Bedford, MA; New London, CT; Norfolk, VA; Paulsboro, NJ; and Providence, RI, as well as Europe. The development of an OSW industry on the Mid-Atlantic OCS could incentivize the expansion or improvement of regional ports to support planned and future projects. Port improvements could include activities like dredging and the development of new overwater structures that could adversely affect benthic resources or invertebrates within the GAA, but no specific improvements are included in the Proposed Action and Alternatives C through F. Any future port expansion incentivized by the Project would be subject to independent NEPA analysis and regulatory approvals requiring full consideration of potential environmental effects. Therefore, these localized and cumulative habitat impacts would have **a negligible** adverse effect on benthic habitats or marine invertebrates during Project construction, O&M, and decommissioning. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, these localized and cumulative habitat impacts would have **a negligible** adverse effect on benthic habitats or marine invertebrates during Project construction, O&M, and decommissioning. |
| Presence of structures: Entanglement, gear loss, gear damage | Constructed and permitted OSW COP projects are introducing 83 structures into the invertebrates GAA. Additionally, commercial and recreational fishing gear are periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. The lost gear, moved by currents, can disturb, injure, or kill benthic resources, creating small short-term, localized impacts. | Future new cables would present additional risk of gear loss, resulting in small short-term, localized impacts (disturbance, injury). | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Presence of structures: Hydrodynamic disturbance | Constructed and permitted OSW COP projects are introducing 83 structures into the invertebrates GAA. Human-made structures, especially tall vertical structures such as foundations for towers of various purposes, continuously alter local water flow at a fine scale. Water flow typically returns to background levels within a relatively short distance from the structure. Therefore, impacts on benthic resources and invertebrates are typically undetectable. Indirect impacts of structures influencing primary productivity and higher trophic levels | Tall vertical structures can increase seafloor scour and sediment suspension. Impacts would likely be highly localized and difficult to detect. Indirect impacts of structures influencing primary productivity and higher trophic levels are possible but are not well understood. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |

|---|---|---|---|---|---|
| | are possible but are not well understood. New structures are periodically added. | | | | |
| Presence of structures: Fish aggregation | Constructed and permitted OSW COP projects are introducing 83 structures into the invertebrates GAA. Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, continuously create uncommon relief in a mostly sandy seascape. Structure-oriented fishes are attracted to these locations. Increased predation upon benthic resources by structure-oriented fishes can adversely affect populations and communities of benthic resources. These impacts are local and permanent. | New cables installed in the GAA over the next 35 years would likely require hard protection atop portions of the route (see the New cable emplacement/maintenance row in this table). Any new towers, buoys, or piers would also create uncommon relief in a mostly flat, sandy seascape. Structure-oriented fishes could be attracted to these locations. Increased predation upon benthic resources by structure-oriented fishes could adversely affect populations and communities of benthic resources. These impacts are expected to be local and permanent as long as the structures remain. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Presence of structures: Habitat conversion | Constructed and permitted OSW COP projects are introducing 83 structures into the invertebrates GAA. Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables continuously provide uncommon hard-bottom habitat. A large portion is homogeneous sandy seascape but there is some other hard and/or complex habitat. Benthic species dependent on hard-bottom habitat and structure-oriented species thus benefit on a constant basis; however, the diversity could decline over time as early colonizers are replaced by successional communities dominated by blue mussels and anemones (Degraer et al. 2019: Chapter 7) and the new habitat can also be colonized by invasive species (e.g., certain tunicate species). Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitat to the new hard-structure habitat. | Any new towers, buoy, piers, or cable protection structures would create uncommon relief in a mostly sandy seascape. Benthic species dependent on hard-bottom habitat could benefit, although the new habitat could also be colonized by invasive species (e.g., certain tunicate species), and the diversity could decline over time as early colonizers are replaced by successional communities dominated by blue mussels and anemones (Degraer et al. 2019: Chapter 7). Soft bottom is the dominant habitat type in the region, and species that rely on this habitat would not likely experience population-level impacts (Greene et al. 2010; Guida et al. 2017). | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Presence of structures: Migration disturbances | Constructed and permitted OSW COP projects are introducing 83 structures into the invertebrates GAA. Human structures in the marine environment (e.g., shipwrecks, artificial reefs, and oil platforms) can attract invertebrates that approach the structures during their migrations. To date, BOEM has not identified any published evidence to suggest that human structures pose a barrier to, or slow, migratory invertebrates. | The infrequent installation of future new structures in the marine environment over the next 35 years could attract invertebrates that approach the structures during their migrations. This could slow migrations. Migratory animals would likely be able to proceed from structures unimpeded. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Presence of structures: Transmission cable infrastructure | Constructed and permitted OSW COP projects are introducing an estimated 498 miles of new offshore cable in the invertebrates GAA. The presence of transmission cable infrastructure, especially hard protection atop cables, causes impacts through entanglement/gear loss/damage, fish aggregation, and habitat conversion. | See other sub-IPFs within Presence of structures rows. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Discharges | Constructed and permitted OSW COP projects can potentially generate operational waste, including bilge and ballast water, sanitary and domestic wastes, and trash and debris in the invertebrates GAA. The gradually increasing amount of vessel traffic is increasing the cumulative permitted discharges from vessels. Many discharges are required to comply with permitting standards established to ensure potential impacts on the environment are minimized or mitigated. However, there does not appear to be evidence that the volumes and extents have any impact on benthic resources. | There is the potential for new ocean dumping/dredge disposal sites in the Northeast. Impacts (disturbance, reduction in fitness) of infrequent ocean disposal to benthic resources are short term because spoils are typically recolonized naturally. In addition, the EPA has established dredge spoil criteria and it regulates the disposal permits issued by the USACE; these discharges are required to comply with permitting standards established to ensure potential impacts on the environment are minimized or mitigated. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Sediment deposition and burial | Ongoing sediment dredging for navigation purposes and installation of permitted OSW COP projects can result in fine sediment deposition. Ongoing cable maintenance activities also infrequently disturb bottom sediments; these disturbances are local and limited to the emplacement corridor. Sediment deposition could have adverse impacts on some benthic resources, especially eggs and larvae, including smothering and loss of fitness—particularly demersal eggs such as longfin squid, which are known to have high rates of egg mortality if egg masses are exposed to abrasion or burial. Impacts could vary based on season/time of year. Where dredged materials are disposed, benthic resources are smothered. However, such areas are typically recolonized naturally in the short term. Most sediment dredging projects have time-of-year restrictions to minimize impacts on benthic resources. Most benthic resources in the GAA are adapted to the turbidity and periodic sediment deposition that occur naturally in the GAA. | The USACE and/or private ports could undertake dredging projects periodically. Where dredged materials are disposed, benthic resources are buried. However, such areas are typically recolonized naturally in the short term. Most benthic resources in the GAA are adapted to the turbidity and periodic sediment deposition that occur naturally in the GAA. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7, and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Vessel traffic | While ongoing OSW and non-OSW vessel activity could have some effect on behavior, it is likely limited to brief startle and temporary stress responses. Ongoing activities that contribute to this sub-IPF include commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. | Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not anticipate vessel traffic to greatly increase over the next 30 years. Even with increased port visits by deep draft vessels, this is still a relatively small adjustment when considering the whole of New England vessel traffic. | **Offshore:** Construction and operational vessel traffic from future wind farm development and decommissioning would not be expected to measurably affect marine invertebrates and benthic habitat structure and composition. Although construction and O&M of vessel cooling systems could entrain planktonic eggs and larvae of fish and invertebrates, leading to injury or mortality of some individuals, these effects are not expected to be measurable relative to natural mortality rates, which can range from 1 to 10% per day or higher (White et al. 2014). Therefore, these effects are unlikely to be significant at the population level. Vessel traffic would have no measurable effects on benthic habitat and benthic or pelagic invertebrates aside from underwater noise exposure and vessel anchoring, which are addressed separately above. Therefore, vessel traffic effects on benthic habitat and invertebrates from the construction, O&M, and decommissioning of planned and potential future OSW energy projects would be **negligible** adverse relative to baseline conditions in the affected environment. | **Offshore:** Construction, O&M, and decommissioning of vessel cooling systems could entrain planktonic eggs and larvae of fish and invertebrates, leading to injury or mortality of individuals. However, these short-term effects are not expected to be measurable relative to natural mortality rates and are therefore unlikely to be significant at the population level. Therefore, vessel traffic effects on invertebrates and benthic habitat would be **negligible** adverse for all Project alternatives and configurations.<br>Although Alternatives C through F would decrease the total number of vessel trips and duration of vessel activity required for O&M and decommissioning relative to the Proposed Action, impacts would remain **negligible** adverse for all Project alternatives.<br>The construction and O&M of all Project alternatives and other planned and potential future OSW energy projects would require the use of construction and operational vessels. This would increase the number of vessels operating in the invertebrate GAA for the foreseeable future. However, vessel-related entrainment mortality is unlikely to be significant at the population level for any invertebrate species. Therefore, vessel traffic cumulative effects on benthic habitat and invertebrates in combination with other planned and potential future OSW energy projects would be **negligible** adverse relative to baseline conditions in the affected environment. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, vessel traffic effects on invertebrates and benthic habitat would be **negligible** adverse for all Project alternatives and configurations.<br>Although Alternative G would decrease the total number of vessel trips and duration of vessel activity required for O&M and decommissioning relative to the Proposed Action, impacts would remain **negligible** adverse for all Project alternatives.<br>Vessel traffic cumulative effects on benthic habitat and invertebrates in combination with other planned and potential future OSW energy projects would be **negligible** adverse relative to baseline conditions in the affected environment. |
| Climate change: Ocean acidification | Ongoing $CO_2$ emissions causing ocean acidification could contribute to reduced growth or the decline of benthic invertebrates that have calcareous shells, as well as reefs and other habitats formed by shells, over the course of the next 35 years. | No future activities were identified within the GAA other than ongoing activities. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |
| Climate change: Warming and sea level rise, altered habitat, ecology, | Climate change, influenced in part by ongoing GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters, influencing the distributions of benthic species and altering ecological relationships, likely causing permanent | No future activities were identified within the GAA other than ongoing activities. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no | See Sections 3.6.2.4 through 3.6.2.7 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on |

|---|---|---|---|---|---|
| and migration patterns | changes of unknown intensity gradually over the next 35 years. | | measurable effect on benthic habitat or invertebrates and are not analyzed. | effect on benthic habitat or invertebrates and are not analyzed. | benthic habitat or invertebrates and are not analyzed. |
| Climate change: Warming and sea level rise, disease frequency | Climate change, influenced in part by ongoing GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters, influencing the frequencies of various diseases of benthic species and likely causing permanent changes of unknown intensity over the next 35 years. | No future activities were identified within the GAA other than ongoing activities. | See Sections 3.6.2.2.2 and 3.6.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.4 through 3.6.2.7 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. | See Sections 3.6.2.8 and 3.6.2.9 and Section 3.6.2.1, Table 3.6-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat or invertebrates and are not analyzed. |

* No constructed and permitted COP projects occur within the benthic habitat GAA. Four constructed and permitted COP projects occur within the invertebrates GAA: Block Island, SFWF, Vineyard Wind 1, and Coastal Virginia Offshore Wind.

## Finfish and Essential Fish Habitat

**Table E2-4. Summary of Activities and the Associated Impact-Producing Factors for Finfish and Essential Fish Habitat**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/hazmat | Constructed and permitted OSW COP projects can accidentally release an estimated 900,000 gallons of fuel, oils, or other hazardous materials in the GAA. See Table E1-4 for a quantitative analysis of these risks. Ongoing releases are frequent/chronic. Impacts, including mortality, decreased fitness, and contamination of habitat, are localized and temporary and rarely affect populations.<br>All vessels would comply with USCG requirements and BSEE regulations for the prevention and control of oil and fuel spills. | Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. Impacts are unlikely to affect populations. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Accidental releases: Invasive species | Invasive species are periodically released accidentally during ongoing activities, including the discharge of ballast water and bilge water from marine vessels. The impacts on finfish and EFH depend on many factors, but can be widespread and permanent. | No future activities were identified within the GAA for this resource other than ongoing activities. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Anchoring | Constructed and permitted OSW COP projects are introducing an estimated 944 acres of anchoring in the GAA. This, combined with vessel anchoring related to other ongoing military use and survey, commercial, and recreational activities continues to cause temporary to permanent impacts in the immediate area where anchors and chains meet | Impacts from anchoring could occur on a semiregular basis over the next 35 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. These impacts would include increased turbidity levels and potential for direct contact, causing mortality of benthic species and, possibly, degradation of sensitive | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | the seafloor. Impacts on finfish and EFH are greatest for sensitive EFH (e.g., eelgrass, hard bottom) and slow-moving species. | habitats. All impacts would be localized; turbidity would be temporary; impacts from direct contact would be recovered in the short term. Degradation of sensitive habitats such as certain types of hard bottom (e.g., boulder piles), if it occurs, could be long term. | | | would have no measurable effect on finfish or EFH and are not analyzed. |
| EMFs | Constructed and permitted OSW COP projects can generate EMF and substrate heating effects, altering the environment for finfish and benthic-associated EFH invertebrates.<br>EMFs also emanate continuously from installed telecommunication and electrical power transmission cables. Biologically significant impacts on finfish and EFH have not been documented for AC cables (CSA Ocean Sciences, Inc. and Exponent 2019; Thomsen et al. 2015), but behavioral impacts have been documented for benthic species (skates and lobster) near operating DC cables (Hutchison et al. 2018). The impacts are localized and affect the animals only while they are within the EMF. There is no evidence to indicate that EMF from undersea AC power cables negatively affects commercially and recreationally important fish species within the southern New England area (CSA Ocean Sciences, Inc. and Exponent 2019). | During operation, future new cables would produce EMF. (See table cell to the left.)<br>Submarine power cables in the GAA for this resource are assumed to be installed with appropriate shielding and burial depth to reduce potential EMF to low levels. EMF of any two sources would not overlap (even for multiple cables within a single export cable corridor). Although the EMF would exist as long as a cable was in operation, impacts, on finfish and EFH would likely be difficult to detect. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Light: Vessels | Nighttime vessel activity associated with permitted and built OSW COP projects is occurring during installation and O&M of various project components (cables, substation etc.). Marine vessels have an array of lights, including navigational lights and deck lights. There is little downward-focused lighting and therefore only a small fraction of the emitted light enters the water. Light can attract finfish, potentially affecting distributions in a highly localized area. Light could also disrupt natural cycles (e.g., spawning), possibly leading to short-term impacts. | See table cell to the left. | Artificial light can attract finfish and can influence or disrupt biological functions (e.g., timing of cod spawning) (Rich and Longcore 2006) that are triggered by changes in daily and seasonal daylight cycles. Planned future activities include up to 3,088 offshore WTGs and OSS foundations. The construction and O&M of these structures would introduce new short-term and long-term sources of artificial light to the offshore environment in the form of vessel lighting and navigation and safety lighting on the structures, respectively. Orr et al. (2013) developed design and mitigation recommendations for reduction of biologically significant impacts from artificial light in OSW infrastructure. Based on these findings, BOEM (2021) has issued design guidance for avoiding and minimizing artificial lighting impacts from such activities and has concluded that adherence to these measures should effectively avoid adverse effects on fish. BOEM would require all future | **Offshore:** Artificial lighting during construction, O&M, and decommissioning at the RWF would be associated with navigational and deck lighting on vessels from dusk to dawn. Lighting would be hooded and directed downward to avoid unnecessary illumination of the surrounding environment to the extent practicable. Reaction of finfish, including EFH species, to this artificial light is highly species dependent and could include attraction and/or avoidance of the area. Artificial lighting could disrupt the migration patterns of fish, increase risk of predation and disrupt predator prey interactions, and alter species' richness and community composition in the affected area (Nightingale et al. 2006; Orr et al. 2013). However, these types of effects are most associated with bright permanent lights on nearshore and overwater structures. The Project would comply with BOEM (2021) issued design guidance for | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, lighting effects on finfish and EFH would be short term to long term **negligible** adverse for Alternative G, with reduced impacts under Alternatives G due to a decrease in total duration of construction vessel activity.<br>BOEM estimates a cumulative total of up to 3,155 offshore WTGs and OSS foundations for Alternative G plus all other future OSW projects in the finfish and EFH GAA. For reasons described in the preceding paragraph, the cumulative impacts associated with all Project alternatives when combined with past, present, and reasonably foreseeable activities would be **negligible** adverse, mostly attributable to existing, ongoing activities. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | offshore energy projects to comply with this guidance. Given the minimal and localized nature of anticipated lighting impacts under this guidance, the related effects from proposed future activities on finfish and EFH in the GAA are likely to be **negligible** adverse. | avoiding and minimizing artificial lighting impacts. Therefore, lighting effects on finfish and EFH would be short term to long-term **negligible** adverse for the Proposed Action and Alternatives C through F, with reduced impacts under Alternatives C through F due to a decrease in total duration of construction vessel activity.<br>BOEM estimates a cumulative total of up to 3,183 offshore WTGs and OSS foundations for the Project plus all other future OSW projects in the finfish and EFH GAA. For reasons described in the preceding paragraph, the cumulative impacts associated with all Project alternatives when combined with past, present, and reasonably foreseeable activities would be **negligible** adverse, mostly attributable to existing, ongoing activities. | |
| Light: Structures | Constructed and permitted OSW COP projects are introducing 83 lighted structures into the GAA. Offshore buoys and towers emit light, and onshore structures, including buildings and ports, emit a great deal more on an ongoing basis. Light can attract finfish, potentially affecting distributions in a highly localized area. Light could also disrupt natural cycles (e.g., spawning), possibly leading to short-term impacts. Light from structures is widespread and permanent near the coast but minimal offshore. | Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast but minimal offshore. | See Light: Vessels for analysis. | See Light: Vessels for analysis of impacts. | See Light: Vessels for analysis of impacts. |
| New cable emplacement/ maintenance | Constructed and permitted OSW COP projects are introducing an estimated 498 miles of new offshore cable in the GAA. This and other non-OSW cable maintenance activities can disturb the seafloor and cause temporary increases in suspended sediment; these disturbances are local and limited to the cable corridor. New cables are infrequently added near shore. Cable emplacement/maintenance activities disturb, displace, and injure finfish and result in temporary to long-term habitat alterations. The intensity of impacts depends on the time (season) and place (habitat type) where the activities occur. (See also the IPF of Sediment deposition and burial.) | Future new cables would occasionally disturb the seafloor and cause temporary increases in suspended sediment, resulting in local short-term impacts.<br>The FCC has two pending submarine telecommunications cable applications in the North Atlantic. If the cable routes enter the GAA for this resource, short-term disturbance would be expected. The intensity of impacts would depend on the time (season) and place (habitat type) where the activities would occur. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Noise: Aircraft | Noise from aircraft reaches the sea surface on a regular basis. However, aircraft noise is not | Aircraft noise is likely to continue to increase as commercial air traffic increases. However, | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for |

Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Noise: Onshore/Offshore construction | Noise from onshore construction associated with permitted OSW COP projects is occurring during installation of various project components (cables, substation etc.). Other noise from construction occurs frequently in nearshores of populated areas in New England and the Mid-Atlantic region but infrequently offshore. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. See also sub-IPF for Noise: Pile driving. | Noise from construction near shorelines is expected to gradually increase in line with human population growth along the coast of the GAA for this resource. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Noise: G&G and scientific surveys | Noise from G&G and scientific surveys associated with permitted OSW COP projects may occur in the GAA. Ongoing site characterization surveys and scientific surveys produce noise around sites of investigation. These activities can disturb finfish in the immediate vicinity of the investigation and can cause temporary behavioral changes. The extent depends on equipment used, noise levels, and local acoustic conditions. | Site characterization surveys, scientific surveys, and exploratory oil and gas surveys are anticipated to occur infrequently over the next 35 years. Seismic surveys used in oil and gas exploration create high-intensity impulsive noise to penetrate deep into the seafloor, potentially resulting in injury or mortality to finfish in a small area around each sound source and short-term stress and behavioral changes to individuals over a greater area. Site characterization surveys typically use sub-bottom profiler technologies that generate less-intense sound waves more similar to common deep-water echosounders. The intensity and extent of the resulting impacts are difficult to generalize, but are likely local and temporary. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Noise: O&M | Noise from O&M associated with built OSW COP projects may occur in the GAA. Some finfish and invertebrates could be able to hear the continuous underwater noise of operational WTGs. As measured at the BIWF, this low frequency noise barley exceeds ambient levels at 164 feet (50 m) from the WTG base. Based on the results of Thomsen et al. (2015), sound pressure levels would be expected to be at or below ambient levels at relatively short distances (approximately 164 feet [50 m]) from WTG foundations. These low levels of elevated noise likely have little to no impact. | New or expanded marine minerals extraction and commercial fisheries could intermittently increase noise during their O&M over the next 35 years. Impacts would likely be small and local. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | Noise is also created by O&M of marine minerals extraction and commercial fisheries, each of which has small local impacts. | | | | |
| Noise: Pile driving | Noise from pile driving associated with permitted OSW COP projects is occurring during installation of foundations for offshore structures. Noise from pile driving also occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or the seafloor can cause injury and/or mortality to finfish in a small area around each pile and can cause short-term stress and behavioral changes to individuals over a greater area. Eggs, embryos, and larvae of finfish and invertebrates could also experience developmental abnormalities or mortality resulting from this noise, although thresholds of exposure are not known (Hawkins and Popper 2017; Weilgart 2018). Potentially injurious noise could also be considered as rendering EFH temporarily unavailable or unsuitable for the duration of the noise. The extent depends on pile size, hammer energy, and local acoustic conditions. | No future activities were identified within the GAA for this resource other than ongoing activities. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Noise: Cable laying/ trenching | Noise from trenching/cable laying associated with permitted OSW COP projects may occur in the GAA. Infrequent trenching activities for other pipeline and cable laying, as well as other cable burial methods, also emit noise. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension. | New or expanded submarine cables and pipelines are likely to occur in the GAA for this resource. These disturbances would be infrequent over the next 35 years, temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of this noise are typically less prominent than the impacts of the physical disturbance and sediment suspension. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Noise: Vessels | While ongoing OSW and non-OSW vessel noise could have some effect on behavior and masking, it is likely limited to brief startle and temporary stress responses. Ongoing activities that contribute to this sub-IPF include permitted and construction OSW COP projects, commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. | See table cell to the left. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Port utilization: Expansion | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the | Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is | The development of an OSW industry on the Mid-Atlantic OCS could incentivize the expansion or improvement of regional ports | **Offshore:** Several regional ports could be used during Project construction, including ports in Baltimore, MD; New Bedford, MA; | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, Project-specific |

|---|---|---|---|---|---|
| | United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance, including dredging. Port utilization is expected to increase over the next 35 years. | expected to continue as human population increases. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and could continue to increase in the foreseeable future. In addition, the general trend along the coast from Virginia to Maine is that port activity would increase modestly. The ability of ports to receive the increase could require port modifications, leading to local impacts.<br>Future channel-deepening activities would likely be undertaken. Existing ports have already affected finfish and EFH, and future port projects would implement BMPs to minimize impacts. Although the degree of impacts on EFH would likely be undetectable outside the immediate vicinity of the ports, adverse impacts on EFH for certain species and/or life stages could lead to impacts on finfish and EFH beyond the vicinity of the port. | to support planned and future projects. Activities like dredging and the expansion or development of new overwater structures could lead to adverse effects on finfish, including EFH species, and coastal and estuarine habitats. Resulting effects on finfish would vary depending on the types of species and habitats present. However, the nature and extent of these impacts cannot currently be quantified as no specific port improvement activities have been proposed. All future port improvements would be subject to independent environmental permitting and regulatory review. Any resulting effects on finfish would be evaluated as part of those efforts. Therefore, impacts to finfish and EFH would be **negligible** adverse. | New London, CT; Norfolk, VA; Paulsboro, NJ; and Providence, RI, as well as Europe. The development of an OSW industry on the Mid-Atlantic OCS could incentivize the expansion or improvement of regional ports to support planned and future projects. Port improvements could include activities like dredging and the development of new overwater structures that could adversely affect finfish and EFH within the GAA, but no specific improvements are included in the Proposed Action and Alternatives C through F. Any future port expansion would be subject to independent NEPA analysis and regulatory approvals requiring full consideration of potential environmental effects.<br>Therefore, Project-specific and cumulative port utilization impacts would be **negligible** adverse. | and cumulative port utilization impacts would be **negligible** adverse. |
| Presence of structures: Entanglement, gear loss, gear damage | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. The lost gear, moved by currents, can disturb habitats and potentially harm individuals, creating small localized, short- to long-term impacts. | No future activities were identified within the GAA for this resource other than ongoing activities. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Presence of structures: Hydrodynamic disturbance | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Human-made structures, especially tall vertical structures such as foundations for towers of various purposes, continuously alter local water flow at a fine scale. Water flow typically returns to background levels within a relatively short distance from the structure. Therefore, impacts on finfish and EFH are typically undetectable. Indirect impacts of structures influencing primary productivity and higher trophic levels are possible but are not well understood. New structures are periodically added. | Tall vertical structures can increase seafloor scour and sediment suspension. Impacts would likely be highly localized and difficult to detect. Indirect impacts of structures influencing primary productivity and higher trophic levels are possible but are not well understood. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Presence of structures: Fish aggregation | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly sandy seascape. | New cables, installed incrementally in the GAA for this resource over the next 20 to 35 years, would likely require hard protection atop portions of the route (see the New cable emplacement/maintenance IPF). Any new towers, buoys, or piers would also create | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | Structure-oriented fishes are attracted to these locations. These impacts are local and often permanent. Fish aggregation could be considered adverse, beneficial, or neutral. | uncommon relief in a mostly sandy seascape. Structure-oriented fishes could be attracted to these locations. Abundance of certain fishes could increase. These impacts are local and could be permanent. | measurable effect on finfish or EFH and are not analyzed. | onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | would have no measurable effect on finfish or EFH and are not analyzed. |
| Presence of structures: Habitat conversion | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly sandy seascape. A large portion is homogeneous sandy seascape, but there is some hard-bottom and/or complex habitat; structure-oriented species thus benefit on a constant basis. Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitat to the new hard-structure habitat. | New cable, installed incrementally in the GAA over the next 20 to 35 years, would likely require hard protection atop portions of the route (see New cable emplacement/maintenance row). Any new towers, buoys, or piers would also create uncommon relief in a mostly sandy seascape. Structure-oriented species would benefit (Claisse et al. 2014; Smith et al. 2016). Soft bottom is the dominant habitat type from Cape Hatteras to the Gulf of Maine (over 60 million acres), and species that rely on this habitat would not likely experience population-level impacts (Guida et al. 2017; Greene et al. 2010). | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Presence of structures: Migration disturbances | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Human-made structures in the marine environment (e.g., shipwrecks, artificial reefs, and oil platforms), can attract finfish that approach the structures during their migrations. This could slow migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement (Fabrizio et al. 2014; Moser and Shepherd 2009; Secor et al. 2018). There is no evidence to suggest that structures pose a barrier to migratory animals. | The infrequent installation of future new structures in the marine environment over the next 35 years could attract finfish that approach the structures during their migrations. This could tend to slow migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement (Fabrizio et al. 2014; Moser and Shepherd 2009; Secor et al. 2018). Migratory animals would likely be able to proceed from structures unimpeded. | See Section 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Presence of structures: Transmission cable infrastructure | See other sub-IPFs within the Presence of structures IPF. | See other sub-IPFs within the Presence of structures IPF | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Sediment deposition and burial | Ongoing sediment dredging for navigation purposes and installation of permitted OSW COP projects can result in fine sediment deposition. Ongoing cable maintenance activities also infrequently disturb bottom sediments; these disturbances are local and limited to the emplacement corridor. Sediment | No future activities were identified within the GAA for this resource other than ongoing activities. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities |

|---|---|---|---|---|---|
| | deposition could have negative impacts on eggs and larvae, including smothering and loss of fitness. Impacts could vary based on season/time of year. | | | | would have no measurable effect on finfish or EFH and are not analyzed. |
| Vessel traffic | Ongoing OSW and non-OSW activities that contribute to this IPF include permitted and constructed OSW COP projects, commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel impacts are largely associated with noise, as discussed above. | Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not anticipate vessel traffic to greatly increase over the next 30 years. Even with increased port visits by deep draft vessels, this is still a relatively small adjustment when considering the whole of New England vessel traffic. Vessel traffic is expected to continue at or near current levels. | Construction and O&M vessel cooling systems could entrain planktonic fish eggs and larvae, leading to injury or mortality of some finfish, including EFH individuals. However, these effects are not expected to be measurable relative to natural mortality rates, which can range from 1 to 10% per day or higher (White et al. 2014) and are therefore unlikely to be significant at the population level. Therefore, vessel traffic effects on finfish and EFH from the construction, O&M, and decommissioning of planned and potential future OSW energy projects would be **negligible** adverse relative to baseline conditions in the affected environment. | Vessels used for Project construction, O&M, and decommissioning could entrain planktonic finfish eggs and larvae in their cooling systems, leading to injury or mortality of individuals. However, these effects are not expected to be measurable relative to natural mortality rates and are therefore unlikely to be significant at the population level. Therefore, vessel traffic effects on finfish and EFH from Project construction, O&M, and decommissioning would be **negligible** adverse.<br>The construction and O&M of the Proposed Action and Alternatives C through F and other planned and potential future OSW energy projects would require the use of construction and operational vessels. This would increase the number of vessels operating in the finfish and EFH GAA for the foreseeable future. While the number of vessels operating in the GAA is large, the number of individual eggs and larvae exposed to entrainment-related mortality effects from individual vessels is negligible relative to natural mortality rates. Therefore, vessel traffic cumulative effects on finfish and EFH from the construction, O&M, and decommissioning of the Proposed Action and Alternatives C through F in combination with other planned and potential future OSW energy projects would be **negligible** adverse relative to baseline conditions in the affected environment. | Similar impacts to the Proposed Action and Alternatives C through F. Therefore, vessel traffic effects on finfish and EFH from Project construction, O&M, and decommissioning would be **negligible** adverse.<br>Vessel traffic cumulative effects on finfish and EFH from the construction, O&M, and decommissioning of Alternatives G in combination with other planned and potential future OSW energy projects would be **negligible** adverse relative to baseline conditions in the affected environment. |
| Climate change: Ocean acidification | Continuous carbon dioxide emissions causing ocean acidification could contribute to reduced growth or the decline of finfish and EFH over the course of the next 35 years. | No future activities were identified within the GAA for this resource other than ongoing activities. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.4 through 3.13.2.7 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |
| Climate change: Warming and sea | Climate change, influenced in part by GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters over the | See above. | See Sections 3.13.2.2.2 and 3.13.2.3.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. | See Sections 3.13.2.8 through 3.13.2.9 and Section 3.13.2.1, Table 3.13-3 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on finfish or EFH and are not analyzed. |

*Includes all constructed and permitted COP projects within the finfish and EFH GAA: Block Island, SFWF, Vineyard Wind 1, and Coastal Virginia Offshore Wind.

## Marine Mammals

**Table E2-5. Summary of Activities and the Associated Impact-Producing Factors for Marine Mammals**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/hazmat | Constructed and permitted OSW COP projects can accidentally release an estimated 900,000 gallons of fuel, oils, or other hazardous materials in the GAA. See Table E1-4 for a quantitative analysis of these risks. Ongoing releases are frequent/chronic. Marine mammal exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality or sublethal effects on individual fitness, including adrenal effects, hematological effects, liver effects lung disease, poor body condition, skin lesions, and several other health affects attributed to oil exposure (Kellar et al. 2017; Mazet et al. 2001; Mohr et al. 2008; Smith et al. 2017; Sullivan et al. 2019; Takeshida et al. 2017). | Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases described for ongoing activities. | **Offshore:** BOEM prohibits the discharge or disposal of solid debris into offshore waters during any activity associated with the construction and operation of offshore energy facilities (30 CFR 250.300). The USCG similarly prohibits the dumping of trash or debris capable of posing entanglement or ingestion risk (MARPOL, Annex V, Public Law 100–220 (101 Stat. 1458)). Baulch and Perry (2014) identified ingested debris as the likely cause of mortality in 22% of beached marine mammal carcasses. Approximately 50% of marine mammal species worldwide have been documented ingesting marine litter (Werner et al. 2016). While development of future OSW facilities and associated marine | **Offshore:** Construction vessels and offshore structures pose a theoretical source of marine debris and entanglement risk and accidental discharges of petroleum products and other toxic substances. Marine debris is a known source of adverse effects to marine mammals (Laist 1997; NOAA-MDP 2014a, 2014b). Revolution Wind would follow strict oil spill prevention and response procedures during all Project phases; would comply with all debris and pollution requirements; and has developed a detailed spill response and containment plan as a Project EPM. These regulatory requirements and the EPM would effectively avoid releases of abandoned marine debris and would avoid and minimize | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, effects on marine mammals from this impact mechanism would be **negligible** adverse for Alternative G.<br>The risk to marine mammals from trash and debris from Alternative G in combination with those from other planned and potential future activities would be **negligible** adverse. Moreover, Alternative G would similarly include the inspection of offshore structures and removal of derelict fishing gear and other accumulated debris. These would provide a **minor** benefit by removing potentially harmful marine debris from the environment. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | Additionally, accidental releases could result in impacts on marine mammals due to effects to prey species (see Table E2-4). All vessels would comply with USCG requirements and BSEE regulations for the prevention and control of oil and fuel spills. | | vessels could be a source of accidental releases of trash and debris, BOEM and USCG requirements would effectively avoid and minimize impacts such that the resulting effects to marine mammals would be **negligible** adverse.<br>BOEM also requires applicants to develop spill response and containment plans to quickly address accidental spills of fuels, lubricants, and other contaminants. A total of approximately 34 million gallons of coolants, fuels, oils, and lubricants could be stored within WTG foundations and OSSs across all projected OSW projects along the Atlantic Coast. A large spill of toxic materials (fuels, lubricants, and other contaminants) could potentially injure or kill several individual marine mammals and adversely affect habitat suitability and would require extensive mitigation to offset. All future OSW projects would be required to comply with regulatory requirements related to the prevention and control of accidental spills administered by the USCG and the BSEE. Oil spill response plans are required for each project and would provide for rapid spill response, cleanup, and other measures that would help to minimize potential impact on affected resources. Given the low probability of a large spill event, impacts to marine mammals from this IPF are likely to be **negligible** adverse. | impacts from accidental spills such that adverse effects on marine mammals are unlikely to occur. In the unlikely event that an accidental spill should occur, individual marine mammals could be injured or killed; habitat suitability could be adversely affected; and extensive mitigation would be required. However, due to the low likelihood of such an event, the temporary nature of the impacts, and established EPMs, effects on marine mammals from this impact mechanism would be **negligible** adverse for the Proposed Action and Alternatives C through F.<br>Existing and planned future OSW-energy development could result in the accidental release of water quality contaminants or trash/debris, which could theoretically lead to an increase in debris and pollution in the marine mammal GAA (see Section 3.15.1 for characterization of existing marine pollution conditions). Compliance with debris and pollution requirements would effectively minimize releases of trash and debris. Given these restrictions, the risk to marine mammals from trash and debris from the Proposed Action and Alternatives C through F in combination with those from other planned and potential future activities is **negligible** adverse. Moreover, the Proposed Action and Alternatives C through F would similarly include the inspection of offshore structures and removal of derelict fishing gear and other accumulated debris. This would provide a **minor** benefit by removing potentially harmful marine debris from the environment. | |
| Accidental releases: Trash and debris | Constructed and permitted OSW COP projects can potentially generate operational waste, including bilge and ballast water, sanitary and domestic wastes, and trash and debris in the GAA. Trash and debris could also be accidentally discharged through fisheries use; dredged material ocean disposal; marine minerals extraction; marine transportation; navigation and traffic; survey activities; and cable, line, and pipeline laying, and debris carried in river outflows or windblown from onshore. Accidental releases of trash and | As population and vessel traffic increase gradually over the next 35 years, accidental release of trash and debris could increase. Trash and debris could continue to be accidentally released through fisheries use and other offshore and onshore activities. There could also be a long-term risk from exposure to plastics and other debris in the ocean. Worldwide, 62 of 123 (50.4%) of marine mammal species have been documented ingesting marine litter (Werner et al. 2016). Mortality has been documented | See Accidental releases: Fuel/fluids/hazmat for analysis. | See Accidental releases: Fuel/fluids/hazmat for analysis. | See Accidental releases: Fuel/fluids/hazmat for analysis. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | debris are expected to be low quantity, local, and low-impact events. Worldwide, 62 of 123 (50.4%) marine mammal species have been documented ingesting marine litter (Werner et al. 2016). Stranding data indicate potential debris induced mortality rates of 0 to 22%. Mortality has been documented in cases of debris interactions as well as blockage of the digestive tract, disease, injury, and malnutrition (Baulch and Perry 2014). However, it is difficult to link physiological effects to individuals to population-level impacts (Browne et al. 2015).<br>All vessels would adhere to federal, state, and local regulations regarding disposal of solid and liquid wastes. | in cases of debris interactions, as well as blockage of the digestive tract, disease, injury, and malnutrition (Baulch and Perry 2014). | | | |
| EMFs | Constructed and permitted OSW COP projects can generate EMF and substrate heating effects, altering the environment for marine mammals.<br>EMFs also emanate constantly from installed telecommunication and electrical power transmission cables. Marine mammals appear to have a detection threshold for magnetic intensity gradients (i.e., changes in magnetic field levels with distance) of 0.1% of the Earth's magnetic field or about 0.05 µT (Kirschvink 1990) and are thus likely to be very sensitive to minor changes in magnetic fields (Walker et al. 2003). There is a potential for animals to react to local variations of the geomagnetic field caused by power cable EMFs. Depending on the magnitude and persistence of the confounding magnetic field, such an effect could cause a trivial temporary change in swim direction or a longer detour during the animal's migration (Gill et al. 2005). Such an effect on marine mammals is more likely to occur with DC cables than with AC cables (Normandeau Associates, Inc. et al. 2011). However, there are numerous transmission cables installed across the seafloor, and no impacts on marine mammals have been demonstrated from this source of EMF. | During operation, future new cables would produce EMF.<br>Submarine power cables in the marine mammal GAA are assumed to be installed with appropriate shielding and at a sufficient burial depth to reduce potential EMF to low levels. EMF of any two sources would not overlap. Although the EMF would exist as long as a cable was in operation, impacts, if any, would likely be difficult to detect, if they occur at all. Marine mammals have the potential to react to submarine cable EMF; however, no effects from the numerous submarine cables have been observed. Further, this IPF would be limited to extremely small portions of the areas used by migrating marine mammals. As such, exposure to this IPF would be low, and as a result, impacts on marine mammals would not be expected. | **Offshore:** Under the No Action Alternative, up to 13,469 miles of cable would be added in the GAA, producing EMF in the immediate vicinity of each cable during operations. BOEM anticipates that the proposed offshore energy projects would use HVAC transmission, but HVDC designs are possible and could occur.<br>EMF effects on marine mammals from these future projects would vary in extent and magnitude depending on overall cable length, the proportion of buried vs. exposed cable segments, and project-specific transmission design (e.g., HVAC or HVDC, transmission voltage, etc.). However, measurable EMF effects are generally limited to within inches to tens of feet of cable corridors, and standard design guidance for OSW energy transmission cable installation (i.e., avoiding cable crossings and maintaining a minimum separation) would limit additive EMF effects from adjacent cables. BOEM would additionally require these future submarine power cables to have appropriate shielding and be at a sufficient burial depth to minimize potential EMF effects from cable operations.<br>At least seven existing submarine power and communications cables are present in the vicinity of the RI/MA WEA. These cables would presumably continue to operate and generate EMF effects under the No Action Alternative. While the type and capacity of | **Offshore:** Exponent (2023) modeled EMF levels that could be generated by the RWEC, OSS-link cable, and IACs. They estimated induced magnetic field levels ranging from 147 to 1,071 mG on the bed surface above the buried and exposed RWEC and OSS-link cable and 57 to 522 mG above the IACs (see the EMF summary table in Sections 3.6.2.4.2 and 3.6.2.7.2). Induced field strength would decrease rapidly with distance from the source, dropping below 100 mG within 3.3 feet of the seafloor directly above the cables. Induced magnetic field strength would fall effectively to 0 mG within 25 feet of the centerline of each cable segment. The only exception would occur at the RWEC landing location, where the two cable corridors would approach to within 10 feet. Measurable magnetic field effects would extend between 25 to 50 feet from the outer edge of the combined cable path.<br>The magnetic field effects generated by exposed segments of the IAC, RWEC, and OSS-link cable are comparable in magnitude to the Earth's natural magnetic field, which is on the order of 517 mG within the RWF. Background magnetic field conditions would fluctuate by 1 to 10 mG from the natural field effects produced by waves and currents. The maximum induced electrical field experienced by any organism close to the exposed cable would be no greater than 0.7 mV/m | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, EMF effects on marine mammals would be **negligible** adverse under Alternative G.<br>Due to the reduced total length of IAC under Alternative G as compared to the Proposed Action, the EMF effects under Alternative G would be similar in nature but proportionally less than under the Proposed Action.<br>Cumulative EMF effects on marine mammals resulting from Alternative G combined with existing, planned, and reasonably foreseeable activities would be **negligible** adverse due to the localized nature of effects and limited anticipated exposure. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | those cables is not specified, the associated baseline EMF effects can be inferred from available literature. Electrical telecommunications cables are likely to induce a weak EMF on the order of 1 to 6.3 µV/m within 3.3 feet (1 m) of the cable path (Gill et al. 2005). Fiber-optic communications cables with optical repeaters would not produce EMF effects. Additionally, literature suggests that most marine species cannot sense low-intensity electric or magnetic fields generated by the HVAC power transmission cables commonly used in OSW energy projects (Gill et al. 2005; Kilfoyle et al. 2018). EMF effects from continued operations of existing submarine power cables would produce similar **negligible** adverse effects on marine mammals for the duration of cable operations because of the localized nature of the effects and limited anticipated exposure. | (Exponent 2023). BOEM has conducted literature reviews and analyses of potential EMF effects from offshore renewable energy projects (CSA Ocean Sciences Inc. and Exponent 2019; Inspire Environmental 2019; Normandeau et al. 2011). These and other available reviews and studies (Gill et al. 2005; Kilfoyle et al. 2018) suggest that most marine species cannot sense low-intensity electric or magnetic fields generated by the HVAC power transmission cables commonly used in OSW energy projects. Normandeau et al. (2011) concluded that marine mammals are unlikely to detect magnetic field intensities below 50 mG, suggesting that these species would be insensitive to EMF effects from Project electrical cables. Project-related EMFs would drop below this threshold and would become undetectable within 3.3 feet (1 m) of the seafloor, except for RWEC cable segments lying on the bed surface. The area exposed to magnetic field effects greater than 50 mG would be small, extending less than 5 feet above the bed surface immediately over the exposed cable segment. The 50-mG detection threshold is theoretical and an order of magnitude lower than the lowest observed magnetic field strength resulting in observed behavioral responses (Normandeau et al. 2011). These factors indicate that the likelihood of marine mammals encountering detectable EMF effects is low, and any exposure would be below levels associated with measurable biological effects.<br>Therefore, EMF effects on marine mammals would be **negligible** adverse under the Proposed Action and Alternatives C through F.<br>Due to the reduced total length of IAC under Alternatives C through F as compared to the Proposed Action, the EMF effects under Alternatives C through F would be similar in nature but proportionally less than under the Proposed Action. Due to the higher capacity of the turbines in Alternative F, there is potential for greater operational noise impacts around each individual turbine, although specifics of these impacts are not certain. | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | BOEM anticipates that most planned facilities would use HVAC transmission, but some could use HVDC. BOEM would require all future projects to use cable designs and EPMs to minimize EMF impacts on the environment. While the range of EMF impacts would vary by project, they are expected to be similar in magnitude to those described for the Proposed Action. Standard design practices for offshore energy cables would avoid cable crossings and maintain a minimum separation of several hundred feet between parallel cable paths where practicable (CSRIC 2014; Sharples 2011; TÜV SÜD PMSS 2014). This would minimize additive EMF effects from multiple cables. On this basis, cumulative EMF effects on marine mammals resulting from the Proposed Action and Alternatives C through F combined with existing, planned, and reasonably foreseeable activities would be **negligible** adverse due to the localized nature of effects and limited anticipated exposure. | |
| Bycatch | Bycatch is a significant population stressor for smaller cetaceans and pinnipeds. NOAA examined the bycatch of 10 species of cetaceans and pinnipeds from the Mid-Atlantic bottom trawl fishery. Mean annual serious injury and mortality estimates for eight of the 10 species were below their potential biological removal (PBR) levels. Bycatch occurs in various gillnet and trawl fisheries in New England and the Mid-Atlantic Coast, with hotspots driven by marine mammal density and fishing intensity (Lewison et al. 2014; NMFS 2018a). | No future activities were identified within the marine mammal GAA other than ongoing activities. | A range of monitoring activities have been proposed to evaluate the short-term and long-term effects of existing and planned OSW development on biological resources and are also likely for future wind energy projects on the OCS. Some of these monitoring activities are likely to affect marine mammals through the potential for bycatch and/or injury by sample collection gear. Biological monitoring uses the same types of methods and equipment employed in commercial fisheries, meaning that impacts would be similar in nature but reduced in extent in comparison impacts from current and likely future fishing activity. Monitoring activities are commonly conducted by commercial fishers under contract who would otherwise be engaged in fishing activity. As such, research and monitoring activities related to OSW would not necessarily result in an increase in bycatch-related impacts on marine mammals, although the distribution of those impacts could change. Therefore, any bycatch-related impacts on marine mammals would be **negligible** to **minor** adverse and short term in duration. | Revolution Wind is proposing to implement the FRMP as part of the Proposed Action and Alternatives C through F (Revolution Wind and Inspire Environmental 2022). The FRMP employs a variety of survey methods to evaluate the effect of RWF construction and operation on benthic habitat structure and composition and on marine species. The following survey methods could impact marine mammals:<br>Ventless trap surveys to evaluate changes in the distribution and abundance of lobster and Jonah crab in the RWF and adjacent reference areas and Jonah crab, lobster, whelk (Buccinidae), and finfish along the RWEC corridor and adjacent reference areas; these areas would be surveyed 12 times per month for 7 months each for 2 years prior to and at least 2 years following completion of Project construction (4 years total)<br>Otter trawl surveys to assess abundance and distribution of target fish and invertebrate species within the RWF could impact a variety of invertebrate species as bycatch, four times per year for 2 years prior to and at least 2 | Similar impacts to Alternatives B through F. Therefore, impacts on marine mammals are anticipated to be **negligible** adverse. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | years following completion of Project construction.<br>These surveys involve similar methods to and would complement other survey efforts conducted by various state, federal, and university entities supporting regional fisheries research and management.<br>Survey fisheries gear (otter trawl surveys, ventless traps, and the anchoring lines and buoys used to secure acoustic telemetry equipment) could pose an entanglement risk to marine mammals. Post-ROD ventless trap surveys would employ ropeless gear retrieval technologies that are consistent with recommendations from NMFS. This would eliminate static vertical lines and surface buoys that are a primary source of gear-related entanglement risk for marine mammals. For trawl surveys, large whale species have the speed and maneuverability to avoid oncoming mobile gear (NMFS 2016), and due to the few proposed trawl surveys and short tow times, impacts on marine mammals are anticipated to be **negligible** adverse.<br>Acoustic telemetry receiver systems pose a negligible risk of harm to marine mammals. Based on the type of equipment and the fact that a small number of receivers deployed (up to 19 total) would be distributed over a large area, BOEM considers the effects of this Project element on marine mammals to be negligible. Similarly, moored and autonomous PAM systems would use the best available technology to reduce any potential risks of entanglement. PAM system deployment would avoid and minimize impacts. Therefore, the effects of this type of survey equipment on marine mammals would be **negligible** adverse. | |
| Light | Constructed and permitted OSW COP projects are introducing 83 lighted structures into the GAA, as well as lighted vessels. Light sources include marine vessels; offshore buoys and towers; and onshore structures, such as buildings and ports. Onshore structures emit a great deal of light on an ongoing basis, greater than offshore structures. Marine | Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast but minimal offshore. | **Offshore:** The addition of up to 3,088 new offshore structures in the GAA with long-term hazard and aviation lighting, as well as lighting associated with construction vessels, would increase artificial lighting. Orr et al. (2013) concluded that the operational lighting effects from wind farm facilities to marine mammal distribution, behavior, and habitat | **Offshore:** Construction of the RWF and RWEC would introduce mobile and intermittent artificial light sources on construction vessels. The RWF would also introduce stationary artificial light sources in the form of navigation, safety, and work lighting. Revolution Wind would follow BOEM (2021) guidance for construction and structural | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, BOEM anticipates that short- to long-term lighting effects from RWF and RWEC construction, operations, and decommissioning on marine mammals would be **negligible** adverse for Alternative G. The effects of this IPF would be similar under |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | vessels have an array of lights, including navigational lights and deck lights. There is little downward-focused lighting and therefore only a small fraction of the emitted light enters the water. Light can attract finfish and invertebrates, potentially affecting distributions in a highly localized area. Light could also disrupt natural cycles (e.g., spawning), possibly leading to short-term impacts. | | use were uncertain but likely negligible if recommended design and operating practices are implemented. BOEM (2021) would require wind farm developers to comply with current design guidance for avoiding and minimizing artificial lighting effects. On this basis, BOEM anticipates artificial lighting impacts from future wind farm development and other offshore activities would result in **negligible** adverse effects on marine mammals for the duration of the offshore activity. | lighting and would use only the minimum type and amount of lighting required by regulation (see Table F-1 in Appendix F). Therefore, BOEM anticipates that short- to long-term lighting effects from RWF and RWEC construction, operations, and decommissioning on marine mammals would be **negligible** adverse for the Proposed Action. The effects of this IPF would be similar under Alternatives C through F but reduced in extent and to the duration of construction activities.<br>The Proposed Action when combined with planned future activities would develop up to 3,183 offshore WTGs and OSS foundations in the GAA. The construction and O&M of these structures would introduce new short-term and long-term sources of artificial light to the offshore environment in the form of vessel lighting and navigation and safety lighting on the structures, respectively. Given the minimal and localized nature of anticipated lighting effects, the cumulative effects from the Proposed Action and Alternatives C through F and existing and planned future activities on marine mammals would be **negligible** adverse, mostly attributable to existing, ongoing activities. | Alternatives C through F but reduced in extent and to the duration of construction activities.<br>Alternative G, when combined with planned future activities, would develop up to 3,155 offshore WTGs and OSS foundations in the GAA. Cumulative effects from Alternative G and existing and planned future activities on marine mammals would be **negligible** adverse, mostly attributable to existing, ongoing activities. |
| New cable emplacement/ maintenance | Constructed and permitted OSW COP projects are introducing an estimated 498 miles of new offshore cable in the GAA. This and other non-OSW cable maintenance activities can disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances would be local and generally limited to the emplacement corridor. Data are not available regarding marine mammal avoidance of localized turbidity plumes; however, Todd et al. (2015) suggest that since some marine mammals often live in turbid waters and some species of mysticetes and sirenians employ feeding methods that create sediment plumes, some species of marine mammals have a tolerance for increased turbidity. Similarly, McConnell et al. (1999) documented movements and foraging of grey seals in the North Sea. One tracked individual was blind in both eyes but otherwise healthy. Despite being blind, | The FCC has two pending submarine telecommunication cable applications in the North Atlantic. The impact on water quality from accidental sediment suspension during cable emplacement is temporary and short term. If elevated turbidity caused any behavioral responses such as avoidance of the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any negative impacts would be temporary and short term. Turbidity associated with increased sedimentation could result in temporary, short-term impacts on some marine mammal prey species (see Table E2-4). | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | observed movements were typical of the other study individuals, indicating that visual cues are not essential for grey seal foraging and movement (McConnell et al. 1999). If elevated turbidity caused any behavioral responses such as avoiding the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any impacts would be temporary and short term. Turbidity associated with increased sedimentation could result in temporary, short-term impacts on marine mammal prey species (see Table E2-4). | | | | |
| Noise: Aircraft | Aircraft routinely travel in the marine mammal GAA. With the possible exception of rescue operations, no ongoing aircraft flights would occur at altitudes that would elicit a response from marine mammals. If flights are at a sufficiently low altitude, marine mammals could respond with behavioral changes, including short surface durations, abrupt dives, and percussive behaviors (i.e., breaching and tail slapping) (Patenaude et al. 2002). These brief responses would be expected to dissipate once the aircraft has left the area. Similarly, aircraft have the potential to disturb hauled out seals if aircraft overflights occur within 2,000 feet (610 m) of a haul out area (Efroymson et al. 2000). However, this disturbance would be temporary, short term, and result in minimal energy expenditure. These brief responses would be expected to dissipate once the aircraft has left the area. | Future low-altitude aircraft activities such as surveys and navy training operations could result in short-term responses of marine mammals to aircraft noise. If flights are at a sufficiently low altitude, marine mammals could respond with behavior changes, including short surface durations, abrupt dives, and percussive behaviors (i.e., breaching and tail slapping) (Patenaude et al. 2002). These brief responses would be expected to dissipate once the aircraft has left the area. | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |
| Noise: G&G | Noise from G&G surveys associated with permitted OSW COP projects may occur in the GAA. Infrequent site characterization surveys and scientific surveys produce high-intensity impulsive noise around sites of investigation. These activities have the potential to result in high-intensity, high-consequence impacts, including auditory injuries, stress, disturbance, and behavioral responses, if present within the ensonified area (NOAA 2018). Survey protocols and underwater noise mitigation procedures are typically implemented to decrease the potential for any marine mammal to be | Same as ongoing activities, with the addition of possible future oil and gas exploration surveys. | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | within the area where sound levels are above relevant harassment thresholds associated with an operating sound source to reduce the potential for behavioral responses and injury (PTS/TTS) close to the sound source. The magnitude of effects, if any, is intrinsically related to many factors, including acoustic signal characteristics, behavioral state (e.g., migrating), biological condition, distance from the source, duration and level of the sound exposure as well as environmental and physical conditions that affect acoustic propagation (NOAA 2018). | | | | |
| Noise: Turbines | Noise from turbine operation associated with permitted and built OSW COP projects occurs in the GAA. Marine mammals would be able to hear the continuous underwater noise of operational WTGs. As measured at the BIWF, this low frequency noise barely exceeds ambient levels at 164 feet (50 m) from the WTG base. Based on the results of Thomsen et al. (2015) and Kraus et al. (2016), sound pressure levels would be expected to be at or below ambient levels at relatively short distances from the WTG foundations. | This sub-IPF does not apply to future non-OSW development. | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |
| Noise: Pile driving | Noise from pile driving associated with permitted OSW COP projects is occurring during installation of foundations for offshore structures. Noise from pile driving also occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seafloor can result in high-intensity, low-exposure level, long-term but localized, intermittent risk to marine mammals. Impacts would be localized in nearshore waters. Pile-driving activities could negatively affect marine mammals during foraging, orientation, migration, predator detection, social interactions, or other activities (Southall et al. 2007). Noise exposure associated with pile-driving activities can interfere with these functions and have the potential to cause a range of responses, including insignificant behavioral changes, avoidance of the ensonified area, PTS, harassment, and ear injury, depending on the intensity and duration of the exposure. | No future activities were identified within the marine mammal GAA other than ongoing activities. | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |

|---|---|---|---|---|---|
| | BOEM assumes that all ongoing and potential future activities would be conducted in accordance with a project-specific IHA to minimize impacts on marine mammals. | | | | |
| Noise: Cable laying/trenching | N/A | Cable laying impacts resulting from future non-OSW activities would be identical to those described for future OSW projects. | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |
| Noise: Vessels | Ongoing OSW and non-OSW activities that contribute to this sub-IPF include permitted and built OSW COP projects, commercial shipping, recreational, and fishing vessels; scientific and academic research vessels; and other construction vessels. The frequency range for vessel noise falls within marine mammals' known range of hearing and would be audible. Noise from vessels presents a long-term and widespread impact on marine mammals across most oceanic regions. While vessel noise could have some effect on marine mammal behavior, it would be expected to be limited to brief startle and temporary stress response. Results from studies on acoustic impacts from vessel noise on odontocetes indicate that small vessels at a speed of 5 knots in shallow coastal water can reduce the communication range for bottlenose dolphins within 164 feet (50 m) of the vessel by 26% (Jensen et al. 2009). Pilot whales in a quieter deep-water habitat could experience a 50% reduction in communication range from a similar size boat and speed (Jensen et al. 2009). Since lower frequencies propagate farther away from the sound source compared to higher frequencies, low-frequency cetaceans are at a greater risk of experiencing Level B harassment produced by vessel traffic. | Any offshore projects that require the use of ocean vessels could result in long term but infrequent impacts on marine mammals, including temporary startle responses, masking of biologically relevant sounds, physiological stress, and behavioral changes. However, BOEM expects that these brief responses of individuals to passing vessels would be unlikely given the patchy distribution of marine mammals and no stock or population-level effects would be expected. | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |
| Port utilization: Expansion | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing | Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from Virginia | The development of an OSW industry on the Mid-Atlantic OCS could incentivize the expansion or improvement of regional ports to support planned and future projects. Port improvements could lead to an increase in vessel traffic during construction (see Section | Several regional ports could be used during Project construction, including ports in Baltimore, MD; New Bedford, MA; New London, CT; Norfolk, VA; Paulsboro, NJ; and Providence, RI, as well as Europe. The development of an OSW industry on the Mid- | Similar impacts to the Proposed Action and Alternatives C through F. Therefore, port utilization impacts associated with the Project would be **negligible** adverse under all Project alternatives. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | continual upgrades and maintenance. Port expansion activities are localized to nearshore habitats and are expected to result in temporary, short-term impacts, if any, on marine mammals. Vessel noise could affect marine mammals, but the response would be expect to be temporary and short term (see Vessels: Noise sub-IPF above). The impacts on water quality from sediment suspension during port expansion activities is temporary, short term and would be similar to those described under the New cable emplacement/maintenance IPF above. | to Maine is that port activity would increase modestly. The ability of ports to receive the increase in larger ships would require port modifications. Future channel-deepening activities are being undertaken to accommodate deeper draft vessels for the Panama Canal locks. The additional traffic and larger vessels could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and could continue to increase in the foreseeable future. Additional impacts associated with the increased risk of vessel strike could also occur (see the Traffic: Vessel collisions sub-IPF below). | 3.16), O&M, and decommissioning. The resulting change in vessel traffic in the GAA cannot be predicted because, while some ports have been identified as possibilities for expansion, no specific project plans have been proposed. Therefore, impacts would be **negligible** adverse. Any future port expansion and associated increase in vessel traffic would be subject to independent NEPA analysis and regulatory approvals requiring full consideration of potential effects on marine mammals regionwide. | Atlantic OCS could incentivize the expansion or improvement of regional ports to support planned and future projects, but no specific improvements are included in the Proposed Action and Alternatives C through F. Any future port expansion would be subject to independent NEPA analysis and regulatory approvals requiring full consideration of potential environmental effects. However, these localized habitat impacts are unlikely to affect marine mammals within the GAA. Therefore, port utilization impacts associated with the Project would be **negligible** adverse under all Project alternatives.<br>Future actions, should they occur, could involve activities like dredging, increases in vessel activity and underwater noise, and the expansion or development of new structures. These activities could lead to adverse effects on coastal and estuarine habitats used by marine mammals and their prey species. These projects could result in cumulative effects on marine mammals, but the extent and significance of these effects cannot be evaluated because no project proposals have been developed. No port improvements have been proposed as part of the Proposed Action and Alternatives C through F and therefore cumulative impacts would be **negligible** adverse. The environmental effects resulting from any future port expansions would be evaluated in independent NEPA analysis, ESA and MMPA compliance documents, and other regulatory approvals for each project. | No port improvements have been proposed as part of Alternative G, and therefore cumulative impacts would be **negligible** adverse. The environmental effects resulting from any future port expansions would be evaluated in independent NEPA analysis, ESA and MMPA compliance documents, and other regulatory approvals for each project. |
| Presence of structures: Entanglement or ingestion of lost fishing gear | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. There are also more than 130 artificial reefs in the Mid-Atlantic region. This sub-IPF could result in long-term, high-intensity impacts but with low exposure due to localized and geographic spacing of artificial reefs. Currently bridge foundations and the BIWF could be considered artificial reefs and could have higher levels of recreational fishing, which increases the chances of marine mammals encountering lost fishing gear, resulting in possible ingestions, entanglement, injury, or death of individuals (Moore and van der Hoop 2012), if present | No future activities were identified within the marine mammal GAA other than ongoing activities. | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |

|---|---|---|---|---|---|
| | nearshore where these structures are located. There are very few, if any, areas within the OCS GAA for marine mammals that would serve to concentrate recreational fishing and increase the likelihood that marine mammals would encounter lost fishing gear. | | | | |
| Presence of structures: Habitat conversion and prey aggregation | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. There are also more than 130 artificial reefs in the Mid-Atlantic region. Hard-bottom (scour control and rock mattresses) and vertical structures (bridge foundations and BIWF WTGs) in a soft-bottom habitat can create artificial reefs, thus inducing the reef effect (NMFS 2015; Taormina et al. 2018). The reef effect is usually considered a beneficial impact, associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for seals and small odontocetes compared to the surrounding soft bottoms. | The presence of structures associated with non-OSW development in nearshore coastal waters has the potential to provide habitat for seals and small odontocetes as well as preferred prey species. This reef effect has the potential to result in long-term, low-intensity benefits. Bridge foundations would continue to provide foraging opportunities for seals and small odontocetes with measurable benefits to some individuals. Hard-bottom (scour control and rock mattresses used to bury the offshore export cables) and vertical structures (i.e., WTG and ESP foundations) in a soft-bottom habitat can create artificial reefs, thus inducing the reef effect (Causon and Gill 2018; Taormina et al. 2018). The reef effect is usually considered a beneficial impact, associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for marine mammals compared to the surrounding soft bottoms. | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |
| Presence of structures: Avoidance/Displacement | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. The presence of structures changes the offshore environment, and their presence could affect marine mammal behavior; however, the likelihood and significance of these effects are difficult to determine. Based on available science, the physical presence of the monopile foundations is unlikely to pose a barrier to the movement of large marine mammals, and even less likely to impede the movement of smaller marine mammals. | Not contemplated for non-OSW facility sources. | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |
| Presence of structures: Behavioral disruption (breeding and migration) | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. The presence of structures changes the offshore environment, and their presence could affect marine mammal behavior; however, the likelihood and significance of | Not contemplated for non-OSW facility sources. | See Section 3.15.2.2.2 for analysis of offshore impacts. |---|---|---|---|---|---|
| | these effects are difficult to determine. Based on available science, structures could cause localized changes to prey distribution but do not suggest a major change in prey availability. Impacts to movement or displacement are described in other cells. | | | effect on marine mammals and are not analyzed. | no measurable effect on marine mammals and are not analyzed. |
| Presence of structures: Displacement into higher risk areas (vessels and fishing) | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. The presence of structures changes the offshore environment, and their presence could affect marine mammal behavior; however, the likelihood and significance of these effects are difficult to determine. Some research has suggested that wind farm operations may lead to long-term displacement of species such as harbor porpoise, but the evidence is mixed, and observed changes in abundance could be more indicative of general population trends than an actual wind farm effect (Nabe-Nielsen et al. 2011; Tielmann and Carstensen 2012; Vallejo et al. 2017). | Not contemplated for non-OSW facility sources. | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |
| Traffic: Vessel collisions | Current OSW and non-OSW activities that are contributing to this sub-IPF include permitted and built OSW COP projects, port traffic levels, fairways, traffic separation schemes, commercial vessel traffic, recreational and fishing activity, and scientific and academic vessel traffic. Vessel strike is relatively common with cetaceans (Kraus et al. 2005) and one of the primary causes of death to NARWs, with as many as 75% of known anthropogenic mortalities of NARWs likely resulting from collisions with large ships along the U.S. and Canadian eastern seaboard (Kite-Powell et al. 2007). Marine mammals are more vulnerable to vessel strike when they are within the draft of the vessel and beneath the surface and not detectable by visual observers. Some conditions that make marine mammals less detectable include weather conditions with poor visibility (e.g., fog, rain, wave height) or nighttime operations. Vessels operating at speeds exceeding 10 knots have been associated with the highest risk for vessel strikes of NARWs (Vanderlaan and Taggart 2007). Reported vessel collisions with whales show that serious injury rarely occurs | Vessel traffic associated with non-OSW development has the potential to result in an increased collision risk. While these impacts would be high consequence, the patchy distribution of marine mammals makes stock or population-level effects unlikely (Navy 2018). | See Section 3.15.2.2.2 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on benthic habitat and are not analyzed. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of offshore impacts. Onshore Project activities would not result in impacts to marine resources. Therefore, IPFs associated with onshore activities would have no measurable effect on marine mammals and are not analyzed. |

|---|---|---|---|---|---|
| | at speeds below 10 knots (Laist et al. 2001). Data show that the probability of a vessel strike increases with the velocity of a vessel (Pace and Silber 2005; Vanderlaan and Taggart 2007). | | | | |
| Sediment deposition and burial | The USACE and/or private ports could undertake dredging projects periodically. Installation of permitted OSW COP projects can also result in fine sediment deposition. Where dredged materials are disposed, marine species could be affected. However, such areas are typically recolonized naturally in the short term. Most species in the GAA are adapted to the turbidity and periodic sediment deposition that occur naturally in the GAA. | No future activities were identified within the GAA for marine mammals other than ongoing activities. | Seafloor disturbance during the installation of transmission cables, sea-to-shore transition construction, and dredging activities would result in elevated suspended sediment concentrations in the water column. Based on modeled and observed TSS impacts for the Proposed Action and other regional wind farm projects (Elliot et al. 2017; RPS 2022; Vinhateiro et al. 2018), and maximum water column TSS concentrations could range from several hundred to several thousand mg/L in proximity to the disturbance and would dissipate below 100 mg/L, usually within minutes to hours of the disturbance, depending on the types of sediments affected. In locations with predominantly sand or coarser sediments, water column effects would be limited to short-term TSS pulses below 100 mg/L extending a few hundred feet downcurrent within approximately 20 feet of the seafloor and dissipating to background conditions within approximately 1 to 2 hours after disturbance.<br>Available information on marine mammal sensitivity to TSS indicates that water quality impacts would have negligible effects on marine mammals. First, periodic TSS concentrations on the order of 100 mg/L at or near the seafloor are within the range of baseline variability. Marine mammals that forage on or near the seafloor are unlikely to be affected by a short-term increase in TSS that is comparable to existing conditions. For example, researchers have observed that visually impaired grey and harbor seals are able to navigate and locate prey just as effectively as their fully sighted counterparts (McConnell et al. 1999; Newby et al. 1970; Todd et al. 2015), indicating that short-term visual impairment would have no measurable effect on foraging ability. While research on TSS sensitivity in dolphins and large whales is generally lacking, these species developed the ability to echolocate by evolving in | RPS (2022) modeled the magnitude and extent of anticipated TSS concentrations resulting from RWF and RWEC construction. Maximum water column TSS concentrations could exceed 500 mg/L in proximity to the disturbance. The majority of water column effects would be limited to short-term TSS pulses below 100 mg/L, occurring in plumes extending approximately 6 to 20 feet off the seafloor and 580 to 4,134 feet downcurrent. Dredging used to level the seafloor and achieve greater burial depths for RWEC installation would produce TSS plumes with concentrations up to 100 mg/L extending from the seafloor to the surface extending from 3,067 to 5,838 feet downcurrent. In most locations, TSS concentrations would dissipate to background conditions within approximately 1 to 2 hours after disturbance; however, in selected locations—specifically at the sea-to-shore transition construction area—TSS concentrations greater than 100 mg/L could linger for up to 36 hours. These modeled estimates are similar to those developed for BIWF construction. The observed extent of TSS impacts at the BIWF turned out to be considerably lower than the modeled estimates (Elliot et al. 2017), indicating that the potential impacts described here are likely conservative. Both the modeled TSS effects, which are conservatively high, and the observed TSS effects were short term and within the range of baseline variability.<br>Based on available information (see No Action Alternative at left) a short-term reduction in visibility would have no meaningful effects on communication, foraging, and predator avoidance, particularly given that measurable TSS impacts would be limited to within 10 to 12 feet of the seafloor in the open ocean waters where marine mammals are most likely to occur. | Similar impacts to the Proposed Action and Alternatives C through F. Therefore marine mammal exposure to water quality effects resulting from construction of all Project alternatives, including Alternative G, would be **negligible** adverse because of the limited sensitivity of marine mammals to TSS and the temporary nature of the impact. Alternative G would result in a shorter overall length of IAC installation, proportionally reducing the extent and duration of suspended sediment impacts relative to the Proposed Action. Those species that are exposed to elevated TSS would unlikely experience measurable effects on behavior, foraging success, or communication.<br>Sediment deposition and burial effects on marine mammals resulting from Project O&M and decommissioning under Alternative G would be temporary **negligible** adverse.<br>BOEM estimates a cumulative total of up to 105,390 acres of seafloor disturbance for Alternative G plus all other future OSW projects in the GAA. As discussed above, TSS effects on marine mammals are likely to be negligible adverse because of limited potential exposure to elevated TSS. No population-level effects on marine mammals are expected from reduced water quality. Therefore, Alternative G when combined with past, present, and reasonably foreseeable activities would result in **negligible** adverse cumulative effects on marine mammals. |

|---|---|---|---|---|---|
| | | | environments having variable and often low visibility (Tyack and Miller 2002). This suggests that a short-term reduction in visibility would have no effect on communication, foraging success, and predator avoidance and would not result in displacement or other observable changes in behavior.<br><br>These factors indicate that marine mammal exposure to water quality effects resulting from construction of future OSW farms would be limited. Those species that are exposed to elevated TSS would be unlikely to experience measurable effects on behavior, foraging success, or communication. On this basis, water quality effects on marine mammals resulting from future OSW farm construction would be **negligible** adverse and short term in duration. | These factors indicate that marine mammal exposure to water quality effects resulting from construction of all Project alternatives would be **negligible** adverse under the Proposed Action and Alternatives C through F because of the limited sensitivity of marine mammals to TSS and the temporary nature of the impact. Alternatives C through F would result in a shorter overall length of IAC installation, proportionally reducing the extent and duration of suspended sediment impacts relative to the Proposed Action. Those species that are exposed to elevated TSS would be unlikely to experience measurable effects on behavior, foraging success, or communication.<br><br>Seafloor disturbance during O&M activities would be limited under all Project alternatives, but reduced in extent under Alternatives C through F. As noted above, the cables are unlikely to require repair or maintenance, but up to 10% of cable protection could need to be replaced over the life of the Project. Replacement of the cable protection could result in localized, temporary increases in TSS. However, consistent with impacts of cable installation, suspended sediment plumes would be limited to within 10 to 12 feet of the seafloor in the open ocean waters where marine mammals are most likely to occur. Potential effects of removal of the cable during decommissioning would be similar in nature to those anticipated for cable installation or replacement of cable protection. Thus, sediment deposition and burial effects on marine mammals resulting from Project O&M and decommissioning under the Proposed Action and Alternatives C through F would be temporary **negligible** adverse.<br><br>BOEM estimates a cumulative total of up to 105,390 acres of seafloor disturbance for the Proposed Action and Alternatives C through F plus all other future OSW projects in the GAA. | | | | | water quality. Therefore, the Proposed Action and Alternatives C through F when combined with past, present, and reasonably foreseeable activities would result in **negligible** adverse cumulative effects on marine mammals. | |
| Climate change: Warming and sea level rise, storm severity/ frequency | Increased storm frequency could result in increased energetic costs for marine mammals and reduced fitness, particularly for juveniles, calves, and pups. | No future activities were identified within the GAA for marine mammals other than ongoing activities. | See Section 3.15.2.2.2 for analysis. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of impacts. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of impacts. |
| Climate change: Ocean acidification | This sub-IPF has the potential to lead to long-term, high-consequence impacts on marine ecosystems by contributing to reduced growth or decline of invertebrates that have calcareous shells. | No future activities were identified within the marine mammal GAA other than ongoing activities. | See Section 3.15.2.2.2 for analysis. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of impacts. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of impacts. |
| Climate change: Warming and sea level rise, altered habitat/ecology | This sub-IPF has the potential to lead to long-term, high-consequence impacts on marine mammals as a result of changes in distribution, reduced breeding and/or foraging habitat availability, and disruptions in migration. | No future activities were identified within the marine mammal GAA other than ongoing activities. | See Section 3.15.2.2.2 for analysis. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of impacts. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of impacts. |
| Climate change: Warming and sea level rise, altered migration patterns | This sub-IPF has the potential to lead to long-term, high-consequence impacts on marine mammal habitat use and migratory patterns. For example, the NARW appears to be migrating differently and feeding in different areas in response to changes in prey densities related to climate change (MacLeod 2009; Nunny and Simmonds 2019; Record et al. 2019). | No future activities were identified within the marine mammal GAA other than ongoing activities. | See Section 3.15.2.2.2 for analysis. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of impacts. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of impacts. |
| Climate change: Warming and sea level rise, increased disease frequency | Climate change, influenced in part by GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters, influencing the frequencies of various diseases of marine mammals, such as Phocine distemper. Climate change is clearly influencing infectious disease dynamics in the marine environment; however, no studies have shown a definitive causal relationship between any components of climate change and increases in infectious disease among marine mammals. This is due in large part to a lack of sufficient data and the likely indirect nature of climate change's impact on these diseases. Climate change could affect the incidence or prevalence of infection, the | No future activities were identified within the marine mammal GAA other than ongoing activities. | See Section 3.15.2.2.2 for analysis. | See Sections 3.15.2.3 and 3.15.2.4 and Section 3.15.2.1, Table 3.15-4 for analysis of impacts. | See Section 3.15.2.5 and Section 3.15.2.1, Table 3.15-4 for analysis of impacts. |

## Sea Turtles

**Table E2-6. Summary of Activities and the Associated Impact-Producing Factors for Sea Turtles**

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/hazmat | Constructed and permitted OSW COP projects can accidentally release an estimated 900,000 gallons of fuel, oils, or other hazardous materials in the GAA. See Table E1-4 for a quantitative analysis of these risks. Ongoing releases are frequent and chronic. Sea turtle exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality (Shigenaka et al. 2010) or sublethal effects on individual fitness, including adrenal effects, dehydration, hematological effects, increased disease incidence, liver effects, poor body condition, skin effects, skeletomuscular effects, and several other health effects that can be attributed to oil exposure (Bembenek-Bailey et al. 2019; Camacho et al. 2013; Mitchelmore et al. 2017; Shigenaka et al. 2010; Vargo et al. 1986). Additionally, accidental releases could result in impacts on sea turtles due to effects on prey species (see Table E2-4). All vessels would comply with USCG requirements and BSEE regulations for the prevention and control of oil and fuel spills. | Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. Sea turtle exposure to aquatic contaminants and inhalation of fumes from oil spills can result in mortality (Shigenaka 2010; Wallace et al. 2010) or sublethal effects on individual fitness, including adrenal effects, dehydration, hematological effects, increased disease incidence, liver effects, poor body condition, skin effects, skeletomuscular effects, and several other health effects that can be attributed to oil exposure (Bembenek-Bailey et al. 2019; Camacho et al. 2013; Mitchelmore et al. 2017; Shigenaka et al. 2010; Vargo et al. 1986). Additionally, accidental releases could result in impacts on sea turtles due to effects on prey species (see Table E2-4). | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |

|---|---|---|---|---|---|
| Accidental releases: Trash and debris | Constructed and permitted OSW COP projects can potentially generate operational waste, including bilge and ballast water, sanitary and domestic wastes, and trash and debris in the GAA. Trash and debris could also be accidentally discharged through fisheries use; dredged material ocean disposal; marine minerals extraction; marine transportation; navigation and traffic; survey activities; cable, line, and pipeline laying; and debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low quantity, local, and low-impact events. Direct ingestion of plastic fragments is well documented and has been observed in all species of sea turtles (Bugoni et al. 2001; Hoarau et al. 2014; Nelms et al. 2016; Schuylar et al. 2014). In addition to plastic debris, ingestion of tar, paper, Styrofoam™, wood, reed, feathers, hooks, lines, and net fragments have also been documented (Thomás et al. 2002). Ingestion can also occur when individuals mistake debris for potential prey items (Gregory 2009; Hoarau et al. 2014; Thomás et al. 2002). Potential ingestion of marine debris varies among species and life history stages due to differing feeding strategies (Nelms et al. 2016). Ingestion of plastics and other marine debris can result in both lethal and sublethal impacts on sea turtles, with sublethal effects more difficult to detect (Gall and Thompson 2015; Hoarau et al. 2014; Nelms et al. 2016; Schuyler et al. 2014). Long-term sublethal effects could include dietary dilution, chemical contamination, depressed immune system function, and poor body condition as well as reduced growth rates, fecundity, and reproductive success. However, these effects are cryptic, and clear causal links are difficult to identify (Nelms et al. 2016).<br>All vessels would adhere to federal, state, and local regulations regarding disposal of solid and liquid wastes. | Trash and debris could be accidentally discharged through fisheries use; dredged material ocean disposal; marine minerals extraction; marine transportation; navigation and traffic; survey activities; cable, line, and pipeline laying; and debris carried in river outflows or windblown from onshore. Accidental releases of trash and debris are expected to be low quantity, local, and low-impact events. Direct and indirect ingestion of plastic fragments and other marine debris is well documented and has been observed in all species of sea turtles (Bugoni et al. 2001; Gregory 2009; Hoarau et al. 2014; Nelms et al. 2016; Schuylar et al. 2014; Thomás et al. 2002). | Anchoring | Constructed and permitted OSW COP projects are introducing an estimated 944 acres of anchoring in the GAA. Vessel anchoring related to other ongoing military use and survey, commercial, and recreational activities also | Impacts from anchoring could occur on a semiregular basis over the next 30 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel | Future OSW projects could disturb up to 8,427 acres of seafloor from anchoring/mooring activities and the installation of associated undersea cables during OSW energy development, causing an increase in suspended | Sea turtles near the Project would likely be foraging, and prey items could include benthic species affected by vessel anchoring and cable emplacement/maintenance. The associated disturbance would be temporary; however, | Project construction and installation of Alternative G would have similar impacts to the Proposed Action and Alternatives C through F. Therefore, impact of Project activities associated |

| **Associated IPF: Sub-IPFs** | **Ongoing Activities*** | **Future Non–Offshore Wind Activities Intensity/Extent** | **Future Offshore Wind Activities Intensity/Extent** | **Proposed Action and Alternatives C through F** | **Alternative G (Preferred Alternative)** |
|---|---|---|---|---|---|
| | continues to cause temporary to permanent impacts in the immediate area where anchors and chains meet the seafloor. | traffic. These impacts would include increased turbidity levels and potential for contact causing mortality of sea turtles. All impacts would be localized; turbidity would be temporary; impacts from contact would be recovered in the short term. | sediment. This disturbance would be both localized and temporary in duration. Entanglement risks to sea turtles from vessel anchoring and cable emplacement are not anticipated. Only larger construction and O&M vessels would anchor to the seafloor, using large heavy anchor chains. No lines or rigging are anticipated for cable installation, and transmission cables and jet plow umbilicals are large in diameter, relatively inflexible, and under constant tension. The likelihood of sea turtle entanglement under these conditions is discountable.<br>In general, impacts to benthic habitats are unlikely to directly affect sea turtles but could indirectly affect these species through impacts on their prey. As discussed in Section 3.6, BOEM anticipates that impacts to benthic habitats and invertebrates would likely range from minor to moderate adverse. Certain sea turtle species, such as loggerheads, that feed on benthic invertebrates could experience short-term reductions in prey availability that are limited in extent, potentially offset by long-term increases in prey abundance from maturing reef effects. Thus, effects of anchoring and new cable emplacement/maintenance on sea turtles under the No Action Alternative would be **negligible** adverse. | some benthic habitat conversion would also occur, as described in Section 3.6. Project construction and installation would temporarily affect available foraging habitat until preconstruction species assemblages are recolonized and recovered. Benthic communities that inhabit dynamic bed (i.e., soft-bottom) habitats typically recover rapidly from construction-related disturbance, usually within 1 year (Dernie et al. 2003; UKBERR 2008), while some organisms associated with complex benthic habitat, like sponges and hydroids, could take a decade or longer to fully recover (Auster and Langton 1999; Collie et al. 2005; Lukens and Selberg 2004; Tamsett et al. 2010). The affected area is also subject to periodic bed disturbance by commercial fishing (CH2M HILL 2018), indicating that construction-related bed disturbance is not expected to measurably alter environmental baseline conditions. Because impacts to foraging habitat are mostly temporary and localized, the impact of Project activities associated with seafloor disturbance on sea turtles would be **negligible** adverse under the Proposed Action and Alternatives C through F but incrementally reduced under Alternatives C through F (a comparison of the benthic habitat disturbance footprints under the different configurations of Alternatives C through E and the Proposed Action is provided in Table 3.6-8, Table 3.6-9, and Table 3.6-10 in Section 3.6).<br>Entanglement risks to sea turtles from vessel anchoring and cable emplacement are not anticipated. Only larger construction and O&M vessels would anchor to the seafloor, using large heavy anchor chains. Per the COP, no divers would be used and no lines or rigging are anticipated for cable installation and maintenance. Transmission cables and jet plow umbilicals are large in diameter, relatively inflexible, and under constant tension throughout installation.<br>Potential anchoring impacts during O&M and decommissioning would be similar to the construction phase but reduced due to fewer anchored vessels. As stated in Section 3.5.2 of the COP, the Project does not anticipate that the IAC, OSS-link cable, and RWEC would | with seafloor disturbance on sea turtles under Alternative G would be **negligible** adverse but incrementally reduced relative to the proposed action and configurations of Alternatives D through F that have more proposed WTGs. A comparison of the benthic habitat disturbance footprints under the different configurations of alternatives and the Proposed Action is provided in Table 3.6-8, Table 3.6-9, and Table 3.6-10 in Section 3.6.<br>Alternative G would incrementally reduce the extent of O&M- and decommissioning-related impacts on sea turtles resulting from Project construction and would therefore be **negligible** adverse because of the temporary and localized nature of the potential impacts.<br>BOEM estimates a cumulative total of 10,520 acres of anchoring and mooring-related disturbance and 104,781 acres of cabling-related disturbance for Alternative G combined with all other future OSW projects within the GAA. Although increases in foraging effort or displacement due to turbidity could occur to individual sea turtles, these temporary effects are not anticipated to lead to population-level effects on sea turtle populations. Vessel anchoring and cable emplacement during construction, O&M, and decommissioning are not anticipated to involve equipment, lines, or rigging that could pose a potential entanglement risk to sea turtles. Therefore, Alternative G when combined with past, present, and reasonably foreseeable projects would result in **negligible** adverse cumulative impacts to sea turtles. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | require significant maintenance. The cables themselves are unlikely to require repair, but up to 10% of cable protection could need to be replaced over the life of the Project. Effects to sea turtles from cable protection maintenance would result primarily from underwater noise, disturbance, and collision risk associated with O&M vessel activity.<br>The IAC, OSS-link cable, and RWEC would be removed from the seafloor during Project decommissioning. Alternatives C through F would result in a reduced total length of IAC and a reduced extent of anchoring impacts relative to the Proposed Action. This would incrementally reduce the extent of O&M- and decommissioning-related impacts on sea turtles resulting from Project construction and would therefore be **negligible** adverse under the Proposed Action and Alternatives C through F because of the temporary and localized nature of the potential impacts.<br>BOEM estimates a cumulative total of 5,803 acres of anchoring and mooring-related disturbance and 25,082 acres of cabling-related disturbance for the Proposed Action combined with all other future OSW projects within the GAA. Impacts from Alternatives C through F would be reduced in extent than the Proposed Action. The duration and magnitude of these effects would vary depending on the types of habitats impacted. Impacts on soft-bottom benthic habitats and associated sea turtle forage species would be expected to fully recover within 18 to 24 months, whereas impacts on complex benthic habitats could take a decade or more to fully recover. While increases in foraging effort or displacement due to turbidity could occur to individual sea turtles, these temporary effects are not anticipated to lead to population-level effects on sea turtle populations. Vessel anchoring and cable emplacement during construction, O&M, and decommissioning are not anticipated to involve equipment, lines, or rigging that could pose a potential entanglement risk to sea turtles. Therefore, the Proposed Action and Alternatives C through F when combined with past, present, and reasonably foreseeable projects would | |

|---|---|---|---|---|---|
| | | | | result in **negligible** adverse cumulative impacts to sea turtles. | |
| Bycatch | Impacts from bycatch are a primary threat to sea turtles (NOAA 2018). A reduction in bycatch has been achieved by the requirement for the use of bycatch mitigation measures. A comparison pre- versus post-regulation mean annual bycatch data for Mid-Atlantic fisheries (otter trawl, gillnet, scallop trawl, scallop dredge, Virginia pound net) showed sea turtle bycatch was reduced from 2,400 incidents to 1,700 and mortality was reduced from 1,000 to 470 based on data over the period 1990 to 2007 (Finkbeiner et al. 2011). In the Atlantic, bycatch occurs in various gillnet and trawl fisheries in New England and the Mid-Atlantic Coast, with hotspots driven by marine mammal density and fishing intensity (Lewison et al. 2014; NMFS 2018a). | No future activities were identified within the GAA for this resource other than ongoing activities | A range of monitoring activities has been proposed to evaluate the short-term and long-term effects of existing and planned OSW development on biological resources and are also likely for future wind energy projects on the OCS. Some of these monitoring activities are likely to affect sea turtles through the potential for bycatch and/or injury by sample collection gear. Biological monitoring uses the same types of methods and equipment employed in commercial fisheries, meaning that impacts to sea turtles would be similar in nature but reduced in extent in comparison to impacts from current and likely future fishing activity. Monitoring activities are commonly conducted by commercial fishers under contract who would otherwise be engaged in fishing activity. As such, research and monitoring activities related to OSW would not necessarily result in an increase in bycatch-related impacts on sea turtles, although the distribution of those impacts could change. Therefore, any bycatch-related impacts on invertebrates would be **negligible to minor** adverse and short term in duration. | Revolution Wind is proposing to implement the FRMP as part of the Proposed Action and Alternatives C through F (Revolution Wind and Inspire Environmental 2022). The FRMP employs a variety of survey methods to evaluate the effect of RWF construction and operation on benthic habitat structure and composition and on marine species. The following survey methods could impact sea turtles:<br>Ventless trap surveys to evaluate changes in the distribution and abundance of lobster and Jonah crab in the RWF and adjacent reference areas and Jonah crab, lobster, whelk (Buccinidae), and finfish along the RWEC corridor and adjacent reference areas; these areas would be surveyed 12 times per month for 7 months each for 2 years prior to and at least 2 years following completion of Project construction (4 years total)<br>Otter trawl surveys to assess abundance and distribution of target fish and invertebrate species within the RWF trawls could impact a variety of invertebrate species as bycatch and would occur four times per year for 2 years prior to and at least 2 years following completion of Project construction.<br>These surveys involve similar methods to and would complement other survey efforts conducted by various state, federal, and university entities supporting regional fisheries research and management.<br>Survey fisheries gear (otter trawls, ventless traps, and the anchoring lines and buoys used to secure acoustic telemetry equipment) could pose an entanglement risk to sea turtles. However, this risk must be considered in the context of ongoing commercial fisheries activity. The FRMP would contract commercial fishing vessels to conduct surveys, using commonly available commercial fishing gear. These contract vessels would likely be engaged in the commercial fishery if not involved in the FRMP, at least at an equivalent, if not greater, level of fishing effort. Therefore, the FRMP would not be likely to measurably change the quantity of | Similar impacts to the Proposed Action and Alternatives C through F. Therefore, the anticipated impacts of the FRMP on sea turtles are anticipated to be **negligible** adverse.<br>Acoustic telemetry receiver systems pose a negligible risk of harm to sea turtles. Based on the type of equipment, deployment near the seafloor, and the small number of receivers deployed (up to 19 in total) over a large area, BOEM considers the effects of this Project element on sea turtles to be **negligible** adverse. Similarly, moored and autonomous PAM systems would use the best available technology to avoid and minimize impacts on the environment. Based on their size and configuration of their mooring systems, PAM buoys pose an insignificant entanglement risk to sea turtles. Therefore, the effects of this type of survey equipment on sea turtles would likewise be **negligible** adverse under Alternative G. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | fishing gear on the Mid-Atlantic OCS or the amount of fishing effort that sea turtles are exposed to by gear type. Moreover, the FRMP would employ several risk-reduction measures. Post-ROD ventless trap surveys would employ ropeless gear retrieval technologies that are consistent with recommendations from NMFS. This would eliminate static vertical lines and surface buoys that are a primary source of gear-related entanglement risk for sea turtles. All trap and pot gear would be stored dry between surveys to minimize the time that gear is in the water.<br>When considered in combination, the anticipated impacts of the FRMP on sea turtles are anticipated to be **negligible** adverse.<br>Acoustic telemetry receiver systems pose a negligible risk of harm to sea turtles. Based on the type of equipment, deployment near the seafloor, and the small number of receivers deployed (up to 19 in total) over a large area, BOEM considers the effects of this Project element on sea turtles to be **negligible** adverse. Similarly, moored and autonomous PAM systems would use the best available technology to avoid and minimize impacts on the environment. Based on their size and configuration of their mooring systems, PAM buoys pose an insignificant entanglement risk to sea turtles. Therefore, the effects of this type of survey equipment on sea turtles would likewise be **negligible** adverse under the Proposed Action and Alternatives C through F. | |
| EMFs | Constructed and permitted OSW COP projects can generate EMF and substrate heating effects, altering the environment for sea turtles.<br>EMFs also emanate constantly from installed telecommunication and electrical power transmission cables. Sea turtles appear to have a detection threshold of magnetosensitivity and behavioral responses to field intensities ranging from 0.0047 to 4000 µT for loggerhead turtles, and 29.3 to 200 µT for green turtles, with other species likely similar due to anatomical, behavioral, and life history similarities (Normandeau et al. 2011). Juvenile or adult sea turtles foraging on benthic organisms could be | During operations, future new cables would produce EMF. Submarine power cables in the GAA for sea turtles are assumed to be installed with appropriate shielding and burial depth to reduce potential EMF to low levels (BOEM 2007: Section 5.2.7). EMF of any two sources would not overlap. Although the EMF would exist as long as a cable was in operation, impacts, if any, would likely be difficult to detect, if they occur at all. Further, this IPF would be limited to extremely small portions of the areas used by resident or migrating sea turtles. As such, exposure to this IPF | Under the No Action Alternative, the future development of planned wind energy projects would result in up to 13,469 miles of new submarine electrical transmission cables in the GAA for sea turtles. Each cable would generate EMF effects within the immediate proximity. The available evidence indicates that sea turtles are magnetosensitive and orient to the Earth's magnetic field for navigation. Although they could be able to detect magnetic fields as low as 0.05 mG, they are unlikely to detect magnetic fields below 50 mG (Normandeau et al. 2011; Snoek et al. 2016). Potential EMF effects would be reduced by cable shielding and burial to an appropriate depth (typically 4–6 feet). Standard | **Offshore:** There would be no EMF produced during construction of the offshore Project structures.<br>The Project would generate EMF along the length of the IACs and offshore RWEC for the life of the Project until decommissioning. These effects would be most intense at locations where the RWEC cannot be buried and is laid on the bed surface covered by a stone or concrete armoring blanket. Approximately 8.8 miles of the RWEC cable, 0.9 mile of the OSS-link, and 15.5 miles of the IAC could be unburied and would require surface armoring. Exponent (2023) modeled EMF levels that could be generated by the RWEC, OSS-link cable, and IAC. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore there would be no EMF produced during construction of the offshore Project structures.<br>Given the limited extent of measurable magnetic field levels and limited potential for mobile species like sea turtles to encounter field levels above detectable thresholds, the effects of Project-related EMF exposure on sea turtles would be **negligible** adverse for the life of the Project. Impacts would be reduced in extent as compared to the Proposed |

|---|---|---|---|---|---|
| | able to detect magnetic fields while they are foraging on the bottom near the cables and up to potentially 82 feet (25 m) in the water column above the cable. Juvenile and adult sea turtles could detect the EMF over relatively small areas near cables (e.g., when resting on the bottom or foraging on benthic organisms near cables or concrete mattresses). There are no data on impacts on sea turtles from EMFs generated by underwater cables, although anthropogenic magnetic fields can influence migratory deviations (Luschi et al. 2007; Snoek et al. 2016). However, any potential impacts from AC cables on turtle navigation or orientation would likely be undetectable under natural conditions and thus would be insignificant (Normandeau et al. 2011). | would be low, and as a result, impacts on sea turtles would not be expected. | design guidance for OSW energy transmission cable installation avoids cable crossings where practicable and recommends maintaining a minimum separation of at least several hundred feet between Project features and existing transmission and communication cables to avoid damaging existing infrastructure and for safety during installation (CSRIC 2014; Sharples 2011; TÜV SÜD PMSS 2014). This separation distance would also avoid additive EMF effects from adjacent cables. Although artificial EMF effects on sea turtles are not well studied, the affected areas would be localized around unburied cable segments and limited to within 3 to 7.5 m of the cable surface (CSA Ocean Sciences Inc. and Exponent 2019). Deviations in migration therefore would have a negligible impact on energy expenditure in sea turtles. EMF effects from future OSW development would similarly be **negligible** adverse because of the limited anticipated exposure. | It estimated induced magnetic field levels ranging from 147 to 1,071 mG on the bed surface above the buried and exposed RWEC and OSS-link cable and 57 to 522 mG above the IAC (see Section 3.6). Induced field strength would decrease rapidly with distance from the source, dropping below 100 mG within 3.3 feet of the seafloor directly above the cable. Induced magnetic field strength would fall effectively to 0 mG within 25 feet of the centerline of each cable segment. The only exception would occur at the RWEC landing location, where the two cable corridors would approach to within 10 feet. Measurable magnetic field effects would extend between 25 to 50 feet from the outer edge of the combined cable path.<br>BOEM has conducted literature reviews and analyses of potential EMF effects from offshore renewable energy projects (CSA Ocean Sciences Inc. 2023; Inspire Environmental 2019; Normandeau et al. 2011). These and other available reviews and studies (Gill et al. 2005; Kilfoyle et al. 2018) suggest that most marine species cannot sense very low-intensity electric or magnetic fields at the typical AC power transmission frequencies associated with offshore renewable energy projects. Normandeau et al. (2011) indicate that sea turtles are magnetosensitive and orient to the Earth's magnetic field for navigation, but they are unlikely to detect magnetic fields below 50 mG. The majority of RWEC and IACs would be buried 4 to 6 feet below the bed surface, reducing the magnetic field in the water column below levels detectable to turtles. The transmission cables could produce magnetic field effects above the 50-mG threshold at selected locations where full burial is not possible; these areas would be localized and limited in extent. Magnetic field strength at these locations would decrease rapidly with distance from the cable and drop to 0 mG within 25 feet. Peak magnetic field strength is below the theoretical 50-mG detection limit along the majority of cable length, only exceeding this threshold above the short cable segments laid on the bed surface. Those EMF effects would dissipate below the 50 mG threshold 3.3 feet (1 m) of the seafloor, except | Action, and the total area exposed would vary depending on the configuration selected (see Tables 3.6-23, 3.6-24, and 3.6-25 in Section 3.6).<br>The potential effects of cable heat to the availability of turtle forage would be **negligible** adverse under Alternative G.<br>Project EMF effects would combine with those generated by the 13,469 miles of new and existing transmission cables from the other new OSW facilities planned on the Mid-Atlantic OCS as well as other existing transmission cables. This represents an extremely small percentage of the GAA for sea turtles and is unlikely to lead to biologically significant effects on sea turtle movement, migration, or foraging patterns.<br>Therefore, the cumulative impacts associated with Alternative G when combined with past, present, and reasonably foreseeable activities would represent a long-term **negligible** adverse impact on sea turtles. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | for RWEC cable segments lying on the bed surface. This indicates that turtles would only be able to detect induced magnetic fields within a few feet of cable segments lying on the bed surface. These cable segments would be relatively short (less than 100 feet long) and widely dispersed. Exponent (2023) concluded that the shielding provided by burial and the grounded metallic sheaths around the cables would effectively eliminate any induced electrical field effects detectable to turtles. Given the limited extent of measurable magnetic field levels and limited potential for mobile species like sea turtles to encounter field levels above detectable thresholds, the effects of Project-related EMF exposure on sea turtles would be **negligible** adverse for the life of the Project for the Proposed Action. Alternatives C through F would result in similar EMF impacts to those described for the Proposed Action, but those impacts would be reduced in extent and the total area exposed would vary depending on the alternative and configuration selected (see Tables 3.6-23, 3.6-24, and 3.6-25 in Section 3.6).<br><br>Heat from the buried RWEC and IACs could affect some benthic organisms that represent forage for turtles, but little is known about the potential change to substrate temperatures that transmission cables might have on the benthos (Taormina et al. 2018). Benthic effects are not expected to impact leatherback turtles as benthic prey are not typically included in their diet. Effects to algal cover (green sea turtle forage) and crustaceans, gastropods, crabs, and bivalves (loggerhead sea turtle forage) could conceivably affect sea turtle foraging opportunities. However, because cables would be buried to a depth of 4 to 6 feet and/or covered with concrete protection, changes in temperature of the substrate at the surface of the seafloor is not anticipated to increase markedly. The potential effects of cable heat to the availability of turtle forage would be **negligible** adverse under the Proposed Action and Alternatives C through F.<br><br>Project EMF effects would combine with those generated by the 10,024 miles of new and existing transmission cables from the other new OSW facilities planned on the Mid-Atlantic OCS | |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | as well as other existing transmission cables. Submarine power cables would be installed with appropriate shielding and at a burial depth to reduce potential EMF at the substrate surface. The RWEC and IACs would maintain a minimum separation of at least several hundred feet from other known cables to avoid inadvertent damage during installation and additive EMF effects from adjacent cables (CSRIC 2014; Sharples 2011; TÜV SÜD PMSS 2014). Additionally, exposure to detectable levels of EMF would be limited to within 25 feet of the small number of areas where cable segments cannot be buried to the anticipated depth. This represents an extremely small percentage of the GAA for sea turtles and is unlikely to lead to biologically significant effects on sea turtle movement, migration, or foraging patterns.<br>Therefore, the cumulative impacts associated with the Proposed Action and Alternatives C through F when combined with past, present, and reasonably foreseeable activities would represent a long-term **negligible** adverse impact on sea turtles. | |
| Light: Vessels | Constructed and permitted OSW COP projects are introducing 83 lighted structures into the GAA, as well as lighted vessels. Ocean vessels such as ongoing commercial vessel traffic, recreational and fishing activity, and scientific and academic research traffic have an array of lights, including navigational, deck, and interior lights. Such lights have some limited potential to attract sea turtles, although the impacts, if any, are expected to be localized and temporary. | Construction, operations, and decommissioning vessels associated with non-OSW activities produce temporary and localized light sources that could result in the attraction or avoidance behavior of sea turtles. These short-term impacts are expected to be of low intensity and occur infrequently. | **Offshore:** Nighttime lighting associated with offshore structures and vessels could represent a source of attraction, avoidance, or other behavioral responses in sea turtles. Although responses to light have been studied in various species and life stages of sea turtles in nesting beach environments, the effects of offshore lighting remain uncertain. Shoreline development is the predominant existing artificial lighting source in the nearshore component of the GAA, whereas vessels, mainly fishing vessels, are the predominant artificial lighting source offshore. Future wind energy development would contribute additional light sources to the offshore component of the GAA, including a temporary increase in light from vessels used during construction and the long-term use of navigational lighting on new WTGs and OSSs. An estimated 3,088 foundations are forecasted for future wind energy construction. Each structure would have minimal white flashing navigational lighting as well as red flashing FAA hazard lights in accordance with BOEM's (2021) | **Offshore:** Lights would be required on vessels and heavy equipment during construction. Most scientific studies on lighting effects on sea turtles were conducted at nesting sites, which do not occur in the RWF and RWEC. Gless et al. (2008) reported that previous studies showed that loggerhead turtles were attracted to lights from longline fishing vessels. Gless et al. (2008) conducted a laboratory study to see if juvenile leatherbacks responded to lights in the same way as loggerheads. Their study showed that leatherbacks either failed to orient or oriented at an angle away from the lights and concluded that there is no convincing evidence that marine turtles are attracted to vessel lights. Limpus (2006) indicates that navigation/anchor lights on top of vessel masts are not impactful but that bright deck lights should be shielded if possible to reduce impacts to sea turtles. Project EPMs (see Table F-1 in Appendix F) stipulate that construction vessel lightingwould be limited to the minimum necessary to ensure safety and to comply with applicable regulations. Additionally, BOEM (2021) has | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, temporary construction lighting and operational lighting effects on sea turtles would be **negligible** adverse.<br>BOEM estimates a cumulative total of 3,155 offshore WTGs and OSS foundations for Alternative G plus all other future OSW projects in the GAA. All future wind farm projects would be expected to follow BOEM design guidance for lighting of offshore structures and avoiding and minimizing artificial lighting impacts from offshore energy facilities and associated construction vessels (BOEM 2021; Orr et al. 2013). Adherence to these measures should effectively avoid adverse effects on aquatic organisms. BOEM would require all future offshore energy projects to comply with this guidance. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | lighting and marking guidelines. Although the potential effects of offshore lighting on juvenile and adult sea turtles is uncertain, WTG lighting is anticipated to have a **negligible** adverse effect on sea turtles based on the lack of observed effects on sea turtles from decades of oil and gas platform operations in the Gulf of Mexico, which can have considerably more lighting than offshore WTGs (BOEM 2021). | issued design guidance for avoiding and minimizing artificial lighting impacts from offshore energy facilities and associated construction vessels and has concluded that adherence to these measures should effectively avoid adverse effects on sea turtles. Considering the EPMs and the fact that construction vessel activity is unlikely to measurably alter baseline vessel light levels, temporary construction lighting effects on sea turtles would be **negligible** adverse.<br>The RWF would include a variety of operational lighting, including navigational lighting for mariners, obstruction lighting for aviators, and vessel/work lighting for O&M (BOEM 2021). Orr et al. (2013) indicated that lights on wind generators flash intermittently for navigation or safety purposes and do not present a continuous light source. Limpus (2006) suggested that intermittent flashing lights with a very short “on” pulse and long “off” interval are nondisruptive to marine turtle behavior, irrespective of the color. Limpus (2006) also indicated that navigation/anchor lights on top of vessel masts are unlikely to adversely affect sea turtles but that bright deck lights should be shielded if possible to reduce impacts to sea turtles.<br>Sea turtles’ typical behavior of remaining predominantly submerged would additionally limit the exposure of individuals to operational lighting. BOEM (2021) has issued design guidance for avoiding and minimizing artificial lighting impacts from offshore energy facilities and has concluded that adherence to these measures should effectively avoid adverse effects on fish. RWF adherence to design guidelines would ensure operational lighting effects on sea turtles would be minimal, temporary, and therefore **negligible** adverse.<br>The Proposed Action would result in negligible incremental impacts to sea turtles through the installation of 102 lighted structures (100 WTGs and two OSSs). This represents approximately 3% of the projected increase in offshore lighting projected under the No Action Alternative. BOEM estimates a cumulative total of 3,110 offshore WTGs and OSS foundations for the Proposed Action plus all other future OSW | Nighttime lighting associated with offshore structures and vessels could represent a source of attraction, avoidance, or other behavioral responses in sea turtles. However, BOEM assumes that all OSW projects would be sited offshore, away from nesting beaches, and would not disorient nesting females or hatchling sea turtles.<br>Because other planned and potential future OSW energy projects would be expected to adhere to the same measures to avoid adverse lighting impacts, Alternative G when combined with past, present, and reasonably foreseeable activities would also represent a **negligible** adverse cumulative impact on sea turtles. |

|---|---|---|---|---|---|
| | | | | projects in the GAA. All future wind farm projects would be expected to follow BOEM design guidance for lighting of offshore structures and avoiding and minimizing artificial lighting impacts from offshore energy facilities and associated construction vessels (BOEM 2021; Orr et al. 2013). Adherence to these measures should effectively avoid adverse effects on aquatic organisms. BOEM would require all future offshore energy projects to comply with this guidance. Nighttime lighting associated with offshore structures and vessels could represent a source of attraction, avoidance, or other behavioral responses in sea turtles. However, BOEM assumes that all OSW projects would be sited offshore, away from nesting beaches, and would not disorient nesting females or hatchling sea turtles.<br>Because other planned and potential future OSW energy projects would be expected to adhere to the same measures to avoid adverse lighting impacts, the Proposed Action when combined with past, present, and reasonably foreseeable activities would also represent a **negligible** adverse cumulative impact on sea turtles.<br>Alternatives C through F would include the same, or similar, extent of light emissions as those described for the Proposed Action but would be reduced based on the reduction in the number of WTGs and other operational lighting elements, resulting in a **negligible** adverse impact. Project lighting represents no more than a 3% projected increase in offshore lighting compared to the No Action Alternative. BOEM estimates a cumulative total of 3,066 to 3,103 offshore WTGs and OSS foundations for Alternatives C through F plus all other future OSW projects in the GAA. Thus, the impacts of operational lighting are also considered **negligible** adverse. | |
| Light: Structures | Constructed and permitted OSW COP projects are introducing 83 lighted structures into the GAA. Artificial lighting on nesting beaches or in nearshore habitats has the potential to result in disorientation to nesting females and hatchling turtles. Artificial lighting on the OCS does not appear to have the same potential for effects. | Non-OSW activities would not be expected to appreciably contribute to this sub-IPF. As such, no impact on sea turtles would be expected. | See Light: Vessels above for offshore and onshore analysis. | See Light: Vessels above for offshore and onshore analysis. | See Light: Vessels above for offshore and onshore analysis. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | Decades of oil and gas platform operations in the Gulf of Mexico, which can have considerably more lighting than offshore WTGs, has not resulted in any known impacts on sea turtles (BOEM 2021). | | | | |
| New cable emplacement/ maintenance | Constructed and permitted OSW COP projects are introducing an estimated 498 miles of new offshore cable in the GAA. This and other non-OSW cable maintenance activities can disturb bottom sediments and cause temporary increases in suspended sediment; these disturbances would be local and generally limited to the emplacement corridor. Data are not available regarding effects of suspended sediments on adult and juvenile sea turtles, although elevated suspended sediments could cause individuals to alter normal movements and behaviors. However, these changes are expected to be too small to be detected (NOAA 2020b). Sea turtles would be expected to swim away from the sediment plume. Elevated turbidity is most likely to affect sea turtles if a plume causes a barrier to normal behaviors, but no impacts would be expected due to swimming through the plume (NOAA 2020b). Turbidity associated with increased sedimentation could result in short-term, temporary impacts on sea turtle prey species (see Table E2-4). | The FCC has two pending submarine telecommunication cable applications in the North Atlantic. The impact on water quality from accidental sediment suspension during cable emplacement is short term and temporary. If elevated turbidity caused any behavioral responses such as avoidance of the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any impacts would be short term and temporary. Turbidity associated with increased sedimentation could result in short-term, temporary impacts on some sea turtle prey species (see Table E2-4). | See Anchoring above for offshore and onshore analysis. | See Anchoring above for offshore and onshore analysis. | See Anchoring above for offshore and onshore analysis. |
| Noise: Aircraft | Aircraft routinely travel in the GAA for sea turtles. With the possible exception of rescue operations, no ongoing aircraft flights would occur at altitudes that would elicit a response from sea turtles. If flights are at a sufficiently low altitude, sea turtles could respond with a startle response (diving or swimming away), altered submergence patterns, and a temporary stress response (NSF and USGS 2011; Samuel et al. 2005). These brief responses would be expected to dissipate once the aircraft has left the area. | Future low-altitude aircraft activities such as surveys and navy training operations could result in short-term responses of sea turtles to aircraft noise. If flights are at a sufficiently low altitude, sea turtles could respond with a startle response (diving or swimming away), altered submergence patterns, and a temporary stress response (NSF and USGS 2011; Samuel et al. 2005). These brief responses would be expected to dissipate once the aircraft has left the area. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1. Table 3.19-2 for analysis. |
| Noise: G&G | Noise from G&G surveys associated with permitted OSW COP projects may occur in the GAA. Infrequent site characterization surveys and scientific surveys produce high-intensity impulsive noise around sites of investigation. These activities have the potential to result in some impacts, including potential auditory | Same as ongoing activities, with the addition of possible future oil and gas exploration surveys. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | injuries, short-term disturbance, behavioral responses, and short-term displacement of feeding or migrating sea turtles, if present within the ensonified area (NSF and USGS 2011). The potential for PTS and TTS is considered possible in proximity to G&G surveys using air guns, but impacts are unlikely as turtles would be expected to avoid such exposure and survey vessels would pass quickly (NSF and USGS 2011). No significant impacts would be expected at the population level. | | | | |
| Noise: HRG | Noise from HRG surveys associated with permitted OSW COP projects may occur in the GAA. Possibly included in site characterization surveys and scientific surveys are high-resolution geophysical (HRG) surveys. HRG surveys could be conducted using one or two air guns as the acoustic source, but they generally use electromechanical sources such as side-scan sonars, shallow- and medium-penetration sub-bottom profilers, and single- or multibeam echosounders. Non-air un HRG sources are often used in combination in order to acquire necessary data during a single deployment. HRG surveys are sometimes conducted using autonomous underwater vehicles equipped with multiple acoustic sources (NMFS 2018b). HRG surveys are typically on a time scale of weeks and higher frequency HRG survey noise resulting from cable route surveys could be less intense than G&G noise from site investigation surveys in WEAs. Impacts include potential auditory injuries, short-term disturbance, behavioral responses, and short-term displacement of feeding or migrating sea turtles, if present within the ensonified area (NSF and USGS 2011). These impacts would be negligible as turtles would be expected to avoid exposure and survey vessels would pass quickly (NSF and USGS 2011). No significant impacts would be expected at the population level. | Same as ongoing activities, with the addition of possible future oil and gas exploration surveys. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Noise: Turbines | Noise from turbine operation associated with permitted and built OSW COP projects occurs in the GAA. Available evidence suggests that typical underwater noise levels from operating WTGs would be below current cumulative injury and behavioral effect thresholds for sea turtles. Operating turbines were determined to produce | This sub-IPF does not apply to future non-OSW development. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1 Table 3.19-2 for analysis. | See Sections 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | underwater noise on the order of 110 to 125 $dB_{RMS}$, occasionally reaching as high as 128 $dB_{RMS}$ in the 10-Hz to 8-kHz range (Tougaard et al. 2020). As measured at the BIWF, low-frequency operational noise barely exceeds ambient levels at 164 feet (50 m) from the WTG base (Miller and Potty 2017). Operational noise impacts would be expected to be negligible. | | | | |
| Noise: Pile driving | Noise from pile driving associated with permitted OSW COP projects is occurring during installation of foundations for offshore structures. Noise from pile driving occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or through the seafloor can result in high-intensity, low-exposure levels and long-term but localized intermittent risk to sea turtles. Impacts, potentially including behavioral responses, masking, TTS, and PTS, would be localized in nearshore waters. Data regarding threshold levels for impacts on sea turtles from sound exposure during pile driving are very limited, and no regulatory threshold criteria have been established for sea turtles. Based on current literature, the following thresholds are used to assess impacts to turtles:<br>Potential mortal injury: 210 dB cumulative SPL or greater than 207 $dB_{PEAK}$ SPL (Popper et al. 2014)<br>Potential mortal injury: 204 $dB_{SEL}$, 232 $dB_{PEAK}$ (PTS), 189 $dB_{SEL}$, 226 $dB_{PEAK}$ (TTS) (Navy 2017)<br>Behavioral harassment: 175 dB referenced to 1 µPa rms (Navy 2017) | No future activities were identified within the GAA for sea turtles other than ongoing activities. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Noise: Cable laying/trenching | N/A | Cable laying impacts resulting from future non-OSW activities would be identical to those described for future OSW projects. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Noise: Vessels | Ongoing OSW and non-OSW activities that contribute to this sub-IPF include permitted and built OSW COP projects, commercial shipping, recreational, and fishing vessels; scientific and academic research vessels; and other construction vessels. The frequency range for vessel noise (10 to 1000 Hz) (MMS 2007) overlaps with sea turtles' known hearing range (less than 1,000 Hz with maximum | See Section 3.16. Any offshore projects that require the use of ocean vessels could result in long-term but infrequent impacts on sea turtles, including temporary startle responses, masking of biologically relevant sounds, physiological stress, and behavioral changes, especially their submergence patterns (NSF and USGS 2011; Samuel et | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | sensitivity between 200 to 700 Hz (Bartol 1994) and would therefore be audible. However, Hazel et al. (2007) suggest that sea turtles' ability to detect approaching vessels is primarily vision-dependent, not acoustic. Sea turtles could respond to vessel approach and/or noise with a startle response (diving or swimming away) and a temporary stress response (NSF and USGS 2011). Samuel et al. (2005) indicated that vessel noise could have an effect on sea turtle behavior, especially their submergence patterns. | al. 2005). However, BOEM expects that these brief responses of individuals to passing vessels would be unlikely given the patchy distribution of sea turtles, and no stock or population-level effects would be expected. | | | |
| Port utilization: Expansion | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance. Port expansion activities are localized to nearshore habitats and are expected to result in short-term, temporary impacts, if any, on sea turtles. Vessel noise could affect sea turtles, but response would be expected to be short- term and temporary (see the Vessels: Noise sub-IPF above). The impact on water quality from sediment suspension during port expansion activities is short term, temporary, and would be similar to those described under the New cable emplacement/maintenance IPF above. | Between 1992 and 2012, global shipping traffic increased fourfold (Tournadre 2014). The U.S. OCS is no exception to this trend, and growth is expected to continue as human population increases. In addition, the general trend along the coastal region from Virginia to Maine is that port activity would increase modestly. The ability of ports to receive the increase in larger ships would require port modifications. Future channel-deepening activities are being undertaken to accommodate deeper draft vessels for the Panama Canal locks. The additional traffic and larger vessels could have impacts on water quality through increases in suspended sediments and the potential for accidental discharges. The increased sediment suspension could be long term depending on the vessel traffic increase. Certain types of vessel traffic have increased recently (e.g., ferry use and cruise industry) and could continue to increase in the foreseeable future. Additional impacts associated with the increased risk of vessel strikes could also occur (see the Traffic: Vessel collisions sub-IPF below). | The development of an OSW industry on the Mid-Atlantic OCS could incentivize the expansion or improvement of regional ports to support planned and future projects. Port improvements could lead to an increase in vessel traffic during construction (see Section 3.16), O&M, and decommissioning. The resulting change in vessel traffic in the GAA cannot be predicted because, while some ports have been identified as possibilities for expansion, no specific project plans have been proposed. Therefore, impacts would be **negligible** adverse. Any future port expansion and associated increase in vessel traffic would be subject to independent NEPA analysis and regulatory approvals requiring full consideration of potential effects on sea turtles regionwide. | **Offshore:** Several regional ports could be used during Project construction, including ports in Baltimore, MD; New Bedford, MA; New London, CT; Norfolk, VA; Paulsboro, NJ; and Providence, RI, as well as Europe. The development of an OSW industry on the Mid-Atlantic OCS could incentivize the expansion or improvement of regional ports to support planned and future projects, but no specific improvements are included in the Proposed Action and Alternatives C through F. Therefore, impacts would be **negligible** adverse. Any future port expansion would be subject to independent NEPA analysis and regulatory approvals requiring full consideration of potential environmental effects.<br><br>Future actions, should they occur, could involve activities like dredging and the expansion or development of new structures that could lead to adverse effects on coastal and estuarine habitats used by sea turtles and their prey species. These projects could result in cumulative effects on sea turtles, but the extent and significance of these effects cannot be evaluated because no project proposals have been developed. Therefore, impacts would be **negligible** adverse. However, the environmental effects resulting from any future port expansions would be evaluated in independent NEPA analysis, ESA compliance documents, and other regulatory approvals for each project. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, impacts would be **negligible** adverse. Any future port expansion would be subject to independent NEPA analysis and regulatory approvals requiring full consideration of potential environmental effects. |
| | | | | **Onshore:** Onshore Project activities would not result in impacts to marine resources regardless of alternative. Therefore, onshore activities and facilities would have no measurable effect on sea turtles and would therefore be **negligible** adverse. | **Onshore:** Onshore Project activities would not result in impacts to marine resources regardless of alternative. Therefore, onshore activities and facilities would have no measurable effect on sea turtles and would therefore be **negligible** adverse. |

|---|---|---|---|---|---|
| Presence of structures: Entanglement or ingestion of lost fishing gear | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. The Mid-Atlantic region also has more than 130 artificial reefs. Currently, bridge foundations and the BIWF could be considered artificial reefs and could have higher levels of recreational fishing, which increases the chances of sea turtles encountering lost fishing gear, resulting in possible ingestions, entanglement, injury, or death of individuals (Berreiros and Raykov 2014; Gregory 2009; Vegter et al. 2014) if present where these structures are located. At the scale of the GAA for sea turtles, there are very few areas that would serve to concentrate recreational fishing and increase the likelihood that sea turtles would encounter lost fishing gear. | No future activities were identified within the GAA for sea turtles other than ongoing activities. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Presence of structures: Habitat conversion and prey aggregation | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. The Mid-Atlantic region also has more than 130 artificial reefs. Hard-bottom (scour control and rock mattresses) and vertical structures (bridge foundations and BIWF WTGs) in a soft-bottom habitat can create artificial reefs, thus inducing the reef effect (NMFS 2015; Taormina et al. 2018). The reef effect is usually considered a beneficial impact, associated with higher densities and biomass of fish and decapod crustaceans (Taormina et al. 2018), providing a potential increase in available forage items and shelter for sea turtles compared to the surrounding soft bottoms. | The presence of structures associated with non-OSW development in nearshore coastal waters has the potential to provide habitat for sea turtles as well as preferred prey species. This reef effect has the potential to result in long-term, low-intensity beneficial impacts. Bridge foundations would continue to provide foraging opportunities for sea turtles, with measurable benefits to some individuals. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Presence of structures: Avoidance/Displacement | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Given that sea turtles are highly mobile and the structures are only 36 to 45 feet in diameter and would be separated by approximately 1 mile, the structural alterations of the water column are unlikely to pose a direct barrier to foraging, migration, or other behaviors of sea turtles. | Not contemplated for non-OSW facility sources. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Presence of structures: Behavioral disruption (breeding and migration) | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Given that sea turtles are highly mobile and the structures are only 36 to 45 feet in diameter and would be separated by approximately 1 mile, the structural alterations of the water column are unlikely to | Not contemplated for non-OSW facility sources. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | pose a direct barrier to foraging, migration, or other behaviors of sea turtles. | | | | |
| Presence of structures: Displacement into higher risk areas (vessels and fishing) | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Given that sea turtles are highly mobile and the structures are only 36 to 45 feet in diameter and would be separated by approximately 1 mile, the structural alterations of the water column are unlikely to pose a direct barrier to foraging, migration, or other behaviors of sea turtles. | Not contemplated for non-OSW facility sources. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Sediment deposition and burial | Ongoing sediment dredging for navigation purposes results in fine sediment deposition. Installation of permitted OSW COP projects can also result in fine sediment deposition. Ongoing cable maintenance activities also infrequently disturb bottom sediments; these disturbances are local and limited to the emplacement corridor.<br>Data are not available regarding effects of suspended sediments on adult and juvenile sea turtles, although elevated suspended sediments could cause individuals to alter normal movements and behaviors. However, these changes are expected to be too small to be detected (NOAA 2020b). Sea turtles would be expected to swim away from the sediment plume. Elevated turbidity is most likely to affect sea turtles if a plume causes a barrier to normal behaviors, but no impacts would be expected due to swimming through the plume (NOAA 2020b). Turbidity associated with increased sedimentation could result in short-term, temporary impacts on sea turtle prey species. | The impact on water quality from sediment suspension during cable emplacement is short term and temporary. If elevated turbidity caused any behavioral responses such as avoidance of the turbidity zone or changes in foraging behavior, such behaviors would be temporary, and any impacts would be short term and temporary. Turbidity associated with increased sedimentation could result in short-term, temporary impacts on some sea turtle prey species. | As previously noted, up to 13,469 miles of cable would be added in the GAA. Cable placement and other related construction activities would disturb the seafloor, creating plumes of fine sediment that would disperse and resettle in the vicinity. Data are not available regarding impacts of suspended sediments on adult and juvenile sea turtles, although elevated suspended sediments could cause individuals to alter normal movements and behaviors. However, these changes would be limited in extent, short term in duration, and likely too small to be detected (NOAA 2020b). Seafloor disturbance during construction of future OSW projects could affect foraging success for some prey species; however, given that impacts would be short term and generally localized to the cable corridor, no population-level effects on sea turtles would be expected. Overall, anticipated effects from sediment deposition and burial on sea turtles would be **negligible** adverse. | **Offshore:** Construction of the RWF and offshore RWEC is expected to result in elevated levels of suspended sediment in the immediate proximity of bed-disturbing activities like pile driving, placement of scour protection, and trenching and burial of the RWEC and IAC. The majority of water column effects would be limited to short-term TSS pulses below 100 mg/L. Higher TSS concentrations exceeding 100 mg/L would occur in areas where seafloor sediments have a greater proportion of mud and silt. TSS plumes caused by construction disturbance would dissipate quickly, with concentrations above 100 mg/L lasting no longer than 6 hours at any location (RPS 2022). A summary of the anticipated extent of water column TSS and substrate burial effects is provided in Section 3.6. These effects would be short term because TSS levels are predicted to return to normal within minutes to hours of activity completion, depending on the magnitude of disturbance and sediments disturbed.<br>Direct physical effects from TSS exposure are unlikely because sea turtles breathe air and do not share the physiological sensitivities of susceptible organisms like fish and invertebrates. Turtles could alter their behavior in response to elevated suspended sediment levels (e.g., moving away from an affected area). They could also experience behavioral stressors (e.g., reduced ability to forage and avoid predators). However, turtles are highly mobile and can avoid short-term suspended sediment impacts that are limited in severity and range. Given the anticipated extent of potential suspended sediment impacts expected to result from the Project, sea turtle | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, effects to sea turtles from elevated suspended sediment levels would be **negligible** adverse. Alternative G would result in similar impacts to sediment deposition and burial to the Proposed Action but reduced in extent and therefore **negligible**. Many sea turtle species routinely inhabit nearshore and estuarine environments with periodically high natural turbidity levels; therefore, short-term exposure to elevated suspended sediment is unlikely to measurably inhibit foraging (Michel et al. 2013). As discussed in Section 3.6, habitat disturbance and resettled sediment are natural ecosystem processes, and impacts on prey and foraging success for sea turtles would also be **negligible** adverse for Alternative G.<br>Sediment deposition and burial effects on sea turtles resulting from Alternative G Project O&M and decommissioning would be temporary **negligible** adverse.<br>BOEM estimates a cumulative total of up to 104,781 acres of seafloor disturbance for the Alternative G plus all other future OSW projects in the GAA. Alternative G would result in impacts similar to the Proposed Action, but the magnitude of those impacts would be reduced based on the smaller footprint proposed for this |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | mobility to avoid exposure, and low sea turtle sensitivity to this stressor, effects to sea turtles from elevated suspended sediment levels would be **negligible** adverse. Alternatives C through F would result in similar impacts to sediment deposition and burial to the Proposed Action but reduced in extent and therefore **negligible**. Many sea turtle species routinely inhabit nearshore and estuarine environments with periodically high natural turbidity levels; therefore, short-term exposure to elevated suspended sediment is unlikely to measurably inhibit foraging (Michel et al. 2013). As discussed in Section 3.6, habitat disturbance and resettled sediment are natural ecosystem processes, and impacts on prey and foraging success for sea turtles would also be **negligible** adverse for the Proposed Action and Alternatives C through F.<br>Seafloor disturbance during O&M activities would be limited. As noted previously, the cables are unlikely to require repair or maintenance, but up to 10% of cable protection could need to be replaced over the life of the Project. Replacement of the cable protection could result in localized, temporary increases in TSS. However, consistent with impacts of cable installation, suspended sediment plumes would be limited to within 10 to 12 feet of the seafloor in the open ocean waters where marine mammals are most likely to occur. Potential effects of removal of the cable during decommissioning would be similar in nature to those anticipated for cable installation or replacement of cable protection. Those species that are exposed to elevated TSS would be unlikely to experience measurable effects on behavior, foraging success, or mobility. Sediment deposition and burial effects on sea turtles resulting from the Proposed Action and Alternatives C through F Project O&M and decommissioning would be temporary **negligible** adverse.<br>BOEM estimates a cumulative total of up to 30,885 acres of seafloor disturbance for the Proposed Action plus all other future OSW projects in the GAA. Alternatives C through F would result in impacts similar to the Proposed Action, but the magnitude of those impacts would be reduced based on the smaller | alternative. As discussed earlier, TSS effects on sea turtles are likely to be negligible adverse because of limited potential exposure to elevated TSS. No population-level effects on sea turtles are expected from reduced water quality. Therefore, Alternative G when combined with past, present, and reasonably foreseeable activities would result in **negligible** adverse cumulative effects on sea turtles. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | footprint proposed for these alternatives. As discussed above, TSS effects on sea turtles are likely to be negligible adverse because of limited potential exposure to elevated TSS. No population-level effects on sea turtles are expected from reduced water quality. Therefore, the Proposed Action and Alternatives C through F when combined with past, present, and reasonably foreseeable activities would result in **negligible** adverse cumulative effects on sea turtles. | |
| Traffic: Vessel collisions | Current OSW and non-OSW activities contributing to this sub-IPF include permitted and built OSW COP projects, port traffic levels, fairways, traffic separation schemes, commercial vessel traffic, recreational and fishing activity, and scientific and academic vessel traffic. Propeller and collision injuries from boats and ships are common in sea turtles. Vessel strike is an increasing concern for sea turtles, especially in the southeastern United States, where development along the coasts is likely to result in increased recreational boat traffic. In the United States, the percentage of strandings of loggerhead sea turtles that were attributed to vessel strikes increased from approximately 10% in the 1980s to a record high of 20.5% in 2004 (NMFS and USFWS 2007). Sea turtles are most susceptible to vessel collisions in coastal waters, where they forage from May through November. Vessel speed could exceed 10 knots in such waters, and evidence suggests that they cannot reliably avoid being struck by vessels exceeding 2 knots (Hazel et al. 2007). | Vessel traffic associated with non-OSW development has the potential to result in an increased collision risk. While these impacts would be high consequence, the patchy distribution of sea turtles makes stock or population-level effects unlikely (Navy 2018). | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Climate change: Warming and sea level rise, storm severity/frequency | Increased storm frequency could lead to long-term, high-consequence impacts on sea turtle onshore beach nesting habitat, including changes to nesting periods, changes in sex ratios of nestlings, and drowned nests as well as loss or degradation of nesting beaches. Offshore impacts, including sedimentation of nearshore hard-bottom habitats, have the potential to result in long-term, high-consequence changes to foraging habitat availability for green turtles. | No future activities were identified within the GAA for sea turtles other than ongoing activities. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Climate change: Ocean acidification | This sub-IPF has the potential to lead to long-term, high-consequence impacts on marine ecosystems by contributing to reduced growth | No future activities were identified within the GAA for sea turtles other than ongoing activities. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | or the decline of invertebrates that have calcareous shells. | | | | |
| Climate change: Warming and sea level rise, altered habitat/ecology | This sub-IPF has the potential to lead to long-term, high-consequence impacts on sea turtles by influencing distributions of sea turtles and/or prey resources. This sub-IPF has the potential to lead to long-term, high-consequence impacts on sea turtle breeding, foraging, and sheltering habitat use. | No future activities were identified within the GAA for sea turtles other than ongoing activities. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Climate change: Warming and sea level rise, altered migration patterns | This sub-IPF has the potential to lead to long-term, high-consequence impacts on sea turtle habitat use and migratory patterns. | No future activities were identified within the GAA for sea turtles other than ongoing activities. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Climate change: Warming and sea level rise, disease frequency | Climate change, influenced in part by GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters, influencing the frequencies of various diseases of sea turtles such as fibropapillomatosis. | No future activities were identified within the GAA for sea turtles other than ongoing activities. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Climate change: Warming and sea level rise, protective measures (barriers, sea walls) | The proliferation of coastline protections have the potential to result in long-term, high-consequence impacts on sea turtle nesting by eliminating or precluding access to potentially suitable nesting habitat or access to potentially suitable habitat. | No future activities were identified within the GAA for sea turtles other than ongoing activities. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |
| Climate change: Warming and sea level rise; storm severity, frequency, sediment erosion, deposition | Sediment erosion and/or deposition in coastal waters has the potential to result in long-term, high-consequence impacts on green sea turtle foraging habitat. Additionally, sediment erosion has the potential to result in the degradation or loss of potentially suitable nesting habitat. | No future activities were identified within the GAA for sea turtles other than ongoing activities. | See Section 3.19.2.2.2 for analysis. | See Sections 3.19.2.3 and 3.19.2.4 and Section 3.19.2.1, Table 3.19-2 for analysis. | See Section 3.19.2.5 and Section 3.19.2.1, Table 3.19-2 for analysis. |

* Includes all constructed and permitted COP projects within the sea turtles GAA: Block Island, SFWF, Vineyard Wind 1, and Coastal Virginia Offshore Wind.

## Demographics, Employment, and Economics

**Table E2-7. Summary of Activities and the Associated Impact-Producing Factors for Demographics, Employment, and Economics**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Energy generation/ security | Constructed and permitted OSW COP projects are slated to provide up to 972 MW of power. In 2017, Massachusetts energy production totaled 125.2 trillion British thermal units (Btu), of which 72.4 trillion Btu was from renewable sources, including geothermal, | Ongoing development of onshore solar and wind energy would provide diversified, small-scale energy generation. State and regional energy markets would require additional peaker plants and energy storage to meet the electricity needs when utility scale renewables are not producing. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |

|---|---|---|---|---|---|
| | hydroelectric, wind, solar, and biomass (U.S. Energy Information Administration 2018).<br>In 2019, Rhode Island energy production totaled 8.8 trillion Btu from renewable resources, including biofuels, wood and waste, and noncombustible renewables. In the same year, Connecticut energy production totaled 211.9 trillion Btu, of which 37.2 trillion Btu was from renewable sources (U.S. Energy Information Administration 2021). | | | | |
| Light: Structures | Constructed and permitted OSW COP projects are introducing 83 lighted structures into the GAA. Offshore buoys and towers also emit low-intensity light, while onshore structures, including houses and ports, emit substantially more light on an ongoing basis. These light sources may be visible at night and could impact employment and economic activity in the tourism industry by affecting the decisions of tourists in selecting coastal locations to visit. | Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast but minimal offshore. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| Light: Vessels | OSW and non-OSW ocean vessels have an array of lights, including navigational lights and deck lights. These light sources may be visible at night and could impact employment and economic activity in the tourism industry by affecting the decisions of tourists in selecting coastal locations to visit. | Anticipated modest growth in vessel traffic would result in some growth in the nighttime traffic of vessels with lighting. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| New cable emplacement/ maintenance | Constructed and permitted OSW COP projects are introducing an estimated 498 miles of new offshore cable in the GAA. This and other non-OSW cable maintenance activities can disturb the seafloor and cause temporary increases in suspended sediment; these disturbances could cause a disruption to commercial fishing or for-hire recreational fishing businesses but would be limited to emplacement corridors. In the GAA for demographics, employment, and economics there are six existing power cables. | The FCC has two pending submarine telecommunication cable applications in the North Atlantic. Future new cables would disturb the seafloor and cause temporary increases in suspended sediment, resulting in infrequent, localized, short-term impacts over the next 35 years. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| Port utilization: Expansion | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also going through continual upgrades and maintenance. The | Ports would need to perform maintenance and upgrade facilities over the next 35 years to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host larger deep draft vessels as they continue to increase in size. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | New Bedford Marine Commerce Terminal was upgraded by the port specifically to support the construction of OSW energy facilities. | | | | |
| Port utilization: Maintenance/ Dredging | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities The major ports in the United States are seeing increased vessel visits, as vessel size also increases. As ports expand, maintenance dredging of shipping channels is expected to increase. | Ports would need to perform maintenance and upgrades over the next 35 years to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host larger deep draft vessels as they continue to increase in size. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| Presence of structures: Allisions | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. To the extent that the impacts of future OSW activities result in declines in the economic performance of commercial and for-hire recreational fisheries, workers employed in these fisheries, including fishing vessel crewmembers and seafood processor workers, could be adversely affected. However, WTG spacing and orientation measures, together with the ability of fishing vessel operators to adjust transit and fishing locations to avoid conflicts with construction related to OSW energy development, would help ensure that fishing businesses could continue to operate with minimal disruption. | Vessel allisions with non-OSW stationary objects should not increase meaningfully without a substantial increase in vessel congestion. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| Presence of structures: Entanglement, gear loss, gear damage | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. Such loss and damage are direct costs for gear owners and are expected to continue at or near current levels. | Reasonably foreseeable activities (non–OSW) would not result in additional offshore structures. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| Presence of structures: Fish aggregation | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these locations, which could be known as fish | Reasonably foreseeable activities (non–OSW) would not result in additional offshore structures. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | aggregating devices (FADs). Recreational and commercial fishing can occur near the FADs, although recreational fishing is more popular because commercial mobile fishing gear is more likely to snag on FADs. | | | | |
| Presence of structures: Habitat conversion | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Structures, including foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly flat seascape. Structure-oriented species thus benefit on a constant basis. Structure-oriented fishes are attracted to these locations, which could be known as FADs. Recreational and commercial fishing can occur near the FADs, although recreational fishing is more popular because commercial mobile fishing gear is more likely to snag on FADs. | Reasonably foreseeable activities (non–OSW) would not result in additional offshore structures. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| Presence of structures: Navigation hazard | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure because vessels need to avoid both the structure and each other. To the extent that the impacts of future OSW activities result in declines in the economic performance of commercial and for-hire recreational fisheries, workers employed in these fisheries, including fishing vessel crewmembers and seafood processor workers, could be adversely affected. However, WTG spacing and orientation measures, together with the ability of fishing vessel operators to adjust transit and fishing locations to avoid conflicts with construction related to OSW energy development, would help ensure that fishing businesses could continue to operate with minimal disruption. | Vessel traffic, overall, is not expected to meaningfully increase over the next 35 years. The presence of navigation hazards is expected to continue at or near current levels. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| Presence of structures: Space use conflicts | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. To the extent that the impacts of future OSW activities result in declines in the economic performance of commercial and for-hire recreational fisheries, workers employed in these fisheries, including fishing vessel | Reasonably foreseeable activities (non–OSW) would not result in additional offshore structures. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |

| | crewmembers and seafood processor workers, could be adversely affected. However, WTG spacing and orientation measures, together with the ability of fishing vessel operators to adjust transit and fishing locations to avoid conflicts with construction related to OSW energy development, would help ensure that fishing businesses could continue to operate with minimal disruption. | | | | |
| Presence of structures: Viewshed | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. These structures are visible from certain views and could impact employment and economic activity in the tourism industry by affecting the decisions of tourists in selecting coastal locations to visit. | Reasonably foreseeable activities (non–OSW) would not result in additional offshore structures. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| Traffic: Vessels | Constructed and permitted OSW COP projects are using vessels to support construction and O&M activities. Ports and marine traffic related to shipping, fishing, and recreation are important to the region's economy. Vessel traffic related to OSW energy project construction can cause congestion and delays, thereby increasing vessel fuel costs (i.e., for vessels forced to wait for port traffic to pass) and decreasing productivity for commercial shipping businesses. | New vessel traffic near the GAA would be generated by proposed barge routes and dredging demolition sites over the next 35 years. Marine commerce and related industries would continue to be important to the economy. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| Traffic: Vessel collisions | The region's substantial OSW and non-OSW marine traffic could result in occasional vessel collisions, which would result in costs to the vessels involved. The likelihood of collisions is expected to continue at or near current rates. | No substantial changes are anticipated. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| Traffic: Vehicle | Onshore OSW and non-OSW development activities support local population growth, employment, and economies. Disturbances can cause temporary, localized traffic delays and restricted access to adjacent properties. | Onshore development projects would be ongoing in accordance with local government land use plans and regulations. | See Section 3.11.2.2.2 for analysis. | See Sections 3.11.2.3 and 3.11.2.4 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. | See Section 3.11.2.5 and Section 3.11.2.1, Table 3.11-5 for analysis of impacts. |
| Climate change | Climate models predict climate change if current trends continue. Climate change has adverse implications for demographics and the economic health of coastal communities, due in part to the costs of resultant damage to property and infrastructure, fisheries and other natural resources, increased disease frequency, and sedimentation, among other factors. | Onshore projects that reduce air emissions could contribute to the effort to limit climate change. Onshore solar and wind energy projects, although producing less energy than potential OSW developments, would also provide incremental reductions. | Because future OSW energy facilities would produce less GHG emissions than fossil fuel–combusting power generation facilities with similar capacities, these facilities would reduce the adverse effects of climate change on the demographic and economic health of coastal communities in the GAA. These beneficial impacts would be long term, but they would be **negligible** adverse given the magnitude of global GHG emissions and their adverse | During operations, the Proposed Action would have a beneficial impact to demographic, employment, or economic conditions in the GAA by contributing to a broader combination of actions to reduce future impacts from climate change over the long term. These beneficial impacts would be long term, but they would be **negligible** adverse given the magnitude of global GHG emissions and their adverse demographic, | Similar impacts to the Proposed Action and Alternatives C through F: long term beneficial **negligible** during operations and cumulatively long term **major** adverse for all design configurations analyzed. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | demographic, employment, and economic impacts. | employment, and economic impacts for all design configurations analyzed under the Proposed Action. Collectively, the Proposed Action when combined with past, present, and reasonably foreseeable projects would have long-term **major** adverse impacts on demographic, employment, and economic conditions in the GAA, primarily through the associated risks of flooding, extreme heat, and storm damage.<br>Alternatives C through F would be similar to that for the Proposed Action: long term beneficial **negligible** during operations and cumulatively long term **major** adverse for all design configurations analyzed. | |

* Includes all constructed and permitted COP projects within the demographics, employment, and economics GAA: Block Island, SFWF, Vineyard Wind 1, and Coastal Virginia Offshore Wind.

## Environmental Justice

No IPFs with solely negligible impacts were identified.

**Table E2-8. Summary of Activities and the Associated Impact-Producing Factors for Environmental Justice**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/hazmat | Constructed and permitted OSW COP projects can accidentally release an estimated 900,000 gallons of fuel, oils, or other hazardous materials in the GAA. Accidental releases of fuels and fluids occur during vessel usage for dredge material ocean disposal; fisheries use; marine transportation; military use; survey activities; and cable, line, and pipeline laying. According to the Department of Energy, 31,000 barrels of petroleum are spilled into U.S. waters from vessels and pipelines in a typical year. Approximately 40.5 million barrels of oil were lost as a result of tanker incidents from 1970 to 2009, according to International Tanker Owners Pollution Federation Limited (2021), which collects data on oil spills from tankers and other sources. From 1990 to 1999, the average annual input to the coastal Northeast was 220,000 barrels of petroleum and into the offshore was < 70,000 barrels. Impacts on water quality would be expected to brief and | Future accidental releases from offshore vessel usage, spills, and consumption would likely continue a similar trend to ongoing uses. Impacts are unlikely to affect water quality. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | localized from accidental releases. All vessels would comply with USCG requirements and BSEE regulations for the prevention and control of oil and fuel spills. | | | | |
| Discharges | Discharges impact water quality by introducing nutrients, chemicals, and sediments to the water. Constructed and permitted OSW COP projects can potentially generate operational waste, including bilge and ballast water, sanitary and domestic wastes, and trash and debris in the GAA. There are regulatory requirements related to prevention and control of discharges, the prevention and control of accidental spills, and the prevention and control of nonindigenous species. | Increased coastal development is causing increased nutrient pollution in communities. In addition, ocean disposal activity in the North and Mid-Atlantic is expected to gradually decrease or remain stable. Impacts of ocean disposal on water quality are minimized because the EPA has established dredge spoil criteria and regulates the disposal permits issued by the USACE.<br>The impact on water quality from sediment suspension during these future activities would be short term and localized. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| Air emissions: Construction/ Decommissioning | Ongoing population growth and new development within the GAA is likely to increase traffic, with a resulting increase in emissions from motor vehicles. Some new industrial development could result in emissions-producing uses. At the same time, many industrial waterfront areas near environmental justice communities are losing industrial uses and converting to more commercial or residential uses.<br>Construction of permitted OSW projects in the GAA is estimated to generate 124,277 tons of $NO_X$, 2,684 tons of $SO_2$, 5,795 tons of $PM_{10}$, and 7,709,706 metric tons of $CO_2e$. Operation of permitted and built OSW projects in the GAA is estimated to generate 2,940 tons of $NO_X$, 44 tons of $SO_2$, 110 tons of $PM_{10}$, and 700,114 metric tons of $CO_2e$. These volumes represent a negligible increase to county emissions; additionally, only a portion of the generated emissions would actually reach nearby counties and would depend on wind conditions at the time the emissions are generated. | New development could include emissions-producing industry and new development that would increase emissions from motor vehicles. Some historically industrial waterfront locations would continue to lose industrial uses, with no new industrial development to replace it. Cities such as New Bedford are promoting start-up space and commercial uses to reuse industrial space. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| Air emissions: O&M | Ongoing population growth and new development within the GAA is likely to increase traffic, with a resulting increase in emissions from motor vehicles. Some new industrial development could result in emissions-producing uses. At the same time, many industrial waterfront areas near | New development could include emissions-producing industry and new development that would increase emissions from motor vehicles. Some historically industrial waterfront locations would continue to lose industrial uses, with no new industrial development to replace it. Cities such as New | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | environmental justice communities are losing industrial uses and converting to more commercial or residential uses.<br>For permitted OSW projects in the GAA, see Air emissions: construction/ decommissioning. | Bedford are promoting start-up space and commercial uses to reuse industrial space. | | | |
| Light: Structures | Constructed and permitted OSW COP projects are introducing 83 lighted structures into the GAA. Offshore buoys and towers also emit low-intensity light, while onshore structures, including houses and ports, emit substantially more light on an ongoing basis. These light sources may be visible at night and could impact employment and economic activity in the tourism industry by affecting the decisions of tourists in selecting coastal locations to visit. | Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast but minimal offshore. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| New cable emplacement/maintenance | Constructed and permitted OSW COP projects are introducing an estimated 498 miles of new offshore cable in the GAA. This and other non-OSW cable maintenance activities can disturb the seafloor and cause temporary increases in suspended sediment; these disturbances could cause a disruption to commercial fishing or for-hire recreational fishing businesses but would be limited to emplacement corridors. | The FCC has two pending submarine telecommunication cable applications in the North Atlantic. Future new cables would disturb the seafloor and cause temporary increases in suspended sediment, resulting in infrequent, localized, and short-term impacts over the next 35 years. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| Noise: O&M | Offshore O&M of constructed and permitted OSW COP projects generates negligible amounts of noise. | There are no reasonably foreseeable offshore facilities that would generate noise from O&M. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| Noise: Pile driving | Noise from pile driving associated with permitted OSW COP projects is occurring during installation of foundations for offshore structures. Noise from pile driving also occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. These disturbances are temporary, local, and extend only a short distance beyond the work area. | No future activities were identified within the GAA other than ongoing activities. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| Noise: Trenching | Noise from trenching/cable laying associated with permitted OSW COP projects may occur in the GAA. Infrequent trenching for other pipeline and cable laying activities also emits noise. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise are typically less prominent | Periodic trenching would be needed over the next 35 years for repair or new installation of underground infrastructure. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | than the impacts of the physical disturbance and sediment suspension. | | | | |
| Noise: Vessels | OSW and non-OSW Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this sub-IPF consist of permitted and built OSW COP projects, commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels. | Planned new barge routes and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| Presence of structures: Entanglement, gear loss/damage | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. Such loss and damage are direct costs for gear owners and are expected to continue at or near current levels. | Reasonably foreseeable activities (non–OSW) would not result in additional offshore structures. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| Presence of structures: Navigation hazard | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure because vessels need to avoid both the structure and each other. To the extent that the impacts of future OSW activities result in declines in the economic performance of commercial and for-hire recreational fisheries, workers employed in these fisheries, including fishing vessel crewmembers and seafood processor workers, could be adversely affected. However, WTG spacing and orientation measures, together with the ability of fishing vessel operators to adjust transit and fishing locations to avoid conflicts with construction related to OSW energy development, would help ensure that fishing businesses could continue to operate with minimal disruption. | Vessel traffic is generally not expected to meaningfully increase over the next 35 years. The presence of navigation hazards is expected to continue at or near current levels. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| Presence of structures: Onshore construction | Onshore OSW and non-OSW development supports local population growth, employment, and economics. | Onshore development would continue in accordance with local government land use plans and regulations. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Presence of structures: Space use conflicts | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. To the extent that the impacts of future OSW activities result in declines in the economic performance of commercial and for-hire recreational fisheries, workers employed in these fisheries, including fishing vessel crewmembers and seafood processor workers, could be adversely affected. However, WTG spacing and orientation measures, together with the ability of fishing vessel operators to adjust transit and fishing locations to avoid conflicts with construction related to OSW energy development, would help ensure that fishing businesses could continue to operate with minimal disruption. | Reasonably foreseeable activities (non–OSW) would not result in additional offshore structures. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| Presence of structures: Viewshed | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. These structures are visible from certain views and could impact employment and economic activity in the tourism industry by affecting the decisions of tourists in selecting coastal locations to visit. | Reasonably foreseeable activities (non–OSW) would not result in additional offshore structures. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| Traffic: Vessels | Constructed and permitted OSW COP projects are using vessels to support construction and O&M activities. Ports and marine traffic related to shipping, fishing, and recreation are important to the region's economy. Vessel traffic related to OSW energy project construction can cause congestion and delays, thereby increasing vessel fuel costs (i.e., for vessels forced to wait for port traffic to pass) and decreasing productivity for commercial shipping businesses. | New vessel traffic near the GAA would be generated by proposed barge routes and dredging demolition sites over the next 35 years. Marine commerce and related industries would continue to be important to employment. | See Section 3.12.2.2.2 for analysis. | See Section 3.12.2.3 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |
| Climate change | Climate models predict climate change if current trends continue. Climate change has adverse implications for demographics and the economic health of coastal communities, due in part to the costs of resultant damage to property and infrastructure, fisheries, and other natural resources; increased disease frequency; and sedimentation, among other factors. Factors that make environmental justice populations particularly vulnerable to the adverse health, safety, and economic impacts of climate change-–related events such as heat waves, heavy flooding, and droughts include where they live, language | Onshore projects that reduce air emissions could contribute to the effort to limit climate change. Onshore solar and wind energy projects, although producing less energy than potential OSW developments, would also provide incremental reductions. | See Section 3.12.2.2.2 for analysis. | See Sections 3.12.2.3 and 3.12.2.4 and Section 3.12.2.1, Table 3.12-4 for analysis of impacts. | See Section 3.12.2.1, Table 3.12-4 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | barriers, their health, and their limited financial resources to cope with these effects (Cho 2020; EPA 2017). The frequency and intensity of climate-related events such as heat waves and heavy flooding are becoming more frequent and more intense across most land regions, and this trend is expected to continue (IPCC 2021). | | | | |

* Includes all constructed and permitted COP projects within the environmental justice GAA: Block Island, SFWF, Vineyard Wind 1, and Coastal Virginia Offshore Wind.

## Cultural Resources

No IPFs with solely negligible impacts were identified.

**Table E2-9**. **Summary of Activities and the Associated Impact-Producing Factors for Cultural Resources**

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/hazmat | Constructed and permitted OSW COP projects can accidentally release an estimated 900,000 gallons of fuel, oils, or other hazardous materials in the viewshed GAA. See Table E1-4 for water quality for a quantitative analysis of these risks. Accidental releases of fuel/fluids/hazmat occur during vessel use for recreational, fisheries, marine transportation, or military purposes and other ongoing activities. Both released fluids and cleanup activities that require the removal of contaminated soils and/or seafloor sediments can cause impacts on cultural resources because resources are impacted by the released chemicals as well as the ensuing cleanup activities. | Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases within the GAA for cultural resources, increasing the frequency of small releases. Although the majority of anticipated accidental releases would be small, resulting in small-scale impacts on cultural resources, a single, large-scale accidental release such as an oil spill, could have significant impacts on marine and coastal cultural resources. A large-scale release would require extensive cleanup activities to remove contaminated materials resulting in damage to or the complete removal of terrestrial and marine cultural resources. In addition, the accidentally released materials in deep water settings could settle on seafloor cultural resources such as wreck sites, accelerating their decomposition and/or covering them and making them inaccessible/unrecognizable to researchers, resulting in a significant loss of historic information. As a result, although considered unlikely, a large-scale accidental release and associated cleanup could result in permanent, geographically extensive, and large-scale impacts on cultural resources. | See Sections 3.10.2.2.2 and 3.10.2.2.3 for analysis. | See Sections 3.10.2.5 and 3.10.2.6 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Trash and debris | Constructed and permitted OSW COP projects can potentially generate operational waste, including bilge and ballast water, sanitary and domestic wastes, and trash and debris in the GAA. Accidental releases of trash and debris also occur during vessel use for recreational, fisheries, marine transportation, or military purposes and other ongoing activities. While the released trash and debris can directly affect cultural resources, the majority of impacts associated with accidental releases occur during cleanup activities, especially if soil or sediment removed during cleanup affect known and undiscovered cultural resources. In addition, the presence of large amounts of trash on shorelines or the ocean surface can impact the cultural value of TCPs for stakeholders. State and federal laws prohibiting large releases of trash would limit the size of any individual release and ongoing local, state, and federal efforts to clean up trash on beaches and waterways would continue to mitigate the effects of small-scale accidental releases of trash. | Future activities with the potential to result in accidental releases consist of construction and operations of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications). Accidental releases would continue at current rates along the Northeast Atlantic Coast. | See Sections 3.10.2.2.2 and 3.10.2.2.3 for analysis. | See Sections 3.10.2.5 and 3.10.2.6 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |
| Anchoring | The use of OSW and non-OSW vessel anchoring and gear (i.e., wire ropes, cables, chains on the seafloor) that disturbs the seafloor, such as bottom trawls and anchors, by military, recreational, industrial, and commercial vessels can impact cultural resources by physically damaging marine cultural resources such as shipwrecks and debris fields. | Future activities with the potential to result in anchoring/gear utilization consist of construction and operations of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); military use; marine transportation; fisheries use and management; and oil and gas activities. These activities are likely to continue to occur at current rates along the entire coast of the eastern United States. | See Section 3.10.2.2.2 for analysis. | See Section 3.10.2.5 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |
| Light: Vessels | Light associated with military, commercial, or OSW and non-OSW construction vessel traffic can temporarily affect coastal historic structures and TCP resources when the addition of intrusive, modern lighting changes the physical environment (setting) of cultural resources. The impacts of construction and operations lighting would be limited to cultural resources on the shoreline for which a nighttime sky is a contributing element to historic integrity. This excludes resources that are closed at night, such as historic buildings, lighthouses, and battlefields, and resources that generate their own nighttime light, such | Future activities with the potential to result in vessel lighting impacts consist of construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Light pollution from vessel traffic would continue at the current intensity along the Northeast coast, with a slight increase due to population increase and development over time. | See Section 3.10.2.2.4 for analysis. | See Section 3.10.2.6 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | as historic districts. Offshore construction activities that require increased vessel traffic, construction vessels stationed offshore, and construction area lighting for prolonged periods can cause more sustained and significant visual impacts on coastal historic structure and TCP resources. | | | | |
| Light: Structures | The construction of new OSW and non-OSW structures that introduce new light sources into the setting of historic architectural properties or TCPs can result in impacts, particularly if the historic and/or cultural significance of the resource is associated with uninterrupted nighttime skies or periods of darkness. Any tall structure (commercial building, radio antenna, large satellite dishes, etc.) requiring nighttime hazard lighting to prevent aircraft collision can cause these types of impacts. | Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast but minimal offshore. | See Section 3.10.2.2.4 for analysis. | See Section 3.10.2.6 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |
| Presence of structures | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA, which are visible from some coastal locations in New York, Connecticut, Rhode Island, and Massachusetts. | Non-OSW structures that could be viewed would be limited to met towers. Marine activity would also occur within the marine viewshed of the GAA. | See Sections 3.10.2.2.2, 3.10.2.2.3, and 3.10.2.2.4 for analysis. | See Sections 3.10.2.5, 3.10.2.6, and 3.10.2.7 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |
| Presence of structures: Onshore construction | Onshore OSW and non-OSW construction activities can impact terrestrial cultural resources by damaging and/or removing resources. | Future activities that could result in terrestrial land disturbance impacts consist of onshore residential, commercial, industrial, and military development activities in and near Quonset Point, Rhode Island. Onshore construction would continue at current rates. | See Section 3.10.2.2.3 for analysis. | See Section 3.10.2.5 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |
| New cable emplacement/ maintenance | Current offshore construction activity is limited to submarine fiber-optic and electrical transmission cables, including six existing power cables in the GAA. Constructed and permitted OSW COP projects are also introducing an estimated 462 miles of new offshore cable in the GAA. Cable installation and maintenance from future OSW activities and other submarine cables could physically impact marine cultural resources. | Future activities with the potential to result in seafloor disturbances similar to offshore impacts consist of construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); tidal energy projects; marine minerals use and ocean-dredged material disposal; military use; and oil and gas activities. Such activities could cause impacts on submerged marine cultural resources, including shipwrecks and formerly subaerially exposed pre-contact Native American cultural sites. | See Sections 3.10.2.2.2 and 3.10.2.2.3 for analysis. | See Sections 3.10.2.5 and 3.10.2.6 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |
| Climate change: Warming and sea level rise, storm severity/frequency | Sea level rise and increased storm severity and frequency would result in impacts on archaeological, architectural, and TCP resources. Increased storm frequency and | Sea level rise and storm severity/frequency would increase due to the effects of climate change. | See Sections 3.10.2.2.2, 3.10.2.2.3, and 3.10.2.2.4 for analysis. | See Sections 3.10.2.5, 3.10.2.6, and 3.10.2.7 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | severity would also result in damage to and/or destruction of architectural properties. Sea level rise would increase erosion-related impacts on archaeological and architectural resources, while sea level rise would inundate archaeological, architectural, and TCP resources. | | | | |
| Climate change: Warming and sea level rise, altered habitat/ecology | Altered habitat/ecology related to warming seas and sea level rise would impact the ability of Native Americans and other communities to use maritime TCPs for traditional fishing, shell fishing, and fowling activities. | The rate of change to habitats/ecology would increase as a result of climate change. | See Sections 3.10.2.2.2, 3.10.2.2.3, and 3.10.2.2.4 for analysis. | See Sections 3.10.2.5, 3.10.2.6, and 3.10.2.7 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |
| Climate change: Warming and sea level rise, altered migration patterns | Altered migration patterns related to warming seas and sea level rise would impact the ability of Native Americans and other communities to use maritime TCPs for traditional fishing, shellfishing, and fowling activities. | The rate of change to migratory animal patterns would increase as a result of climate change. | See Sections 3.10.2.2.2, 3.10.2.2.3, and 3.10.2.2.4 for analysis. | See Sections 3.10.2.5, 3.10.2.6, and 3.10.2.7 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |
| Climate change: Warming and sea level rise, property/ infrastructure damage | Sea level rise and increased storm severity and frequency would result in impacts on archaeological, architectural, and TCP resources. Increased storm frequency and severity would result in damage to and/or destruction of architectural properties. Sea level rise would increase erosion-related impacts on archaeological and architectural resources, while sea level rise would inundate archaeological, architectural, and TCP resources. | The rate of property and infrastructure damage would increase as a result of climate change. | See Sections 3.10.2.2.2, 3.10.2.2.3, and 3.10.2.2.4 for analysis. | See Sections 3.10.2.5, 3.10.2.6, and 3.10.2.7 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |
| Climate change: Warming and sea level rise, protective measures (barriers, sea walls) | The installation of protective measures such as barriers and sea walls would impact cultural resources during associated ground-disturbing activities. Construction of these modern protective structures would alter the viewsheds from historic properties and/or TCPs, resulting in impacts on the historic and/or cultural significance of resources. | The installation of coastal protective measures would increase as a result of climate change. | See Sections 3.10.2.2.2, 3.10.2.2.3, and 3.10.2.2.4 for analysis. | See Sections 3.10.2.5, 3.10.2.6, and 3.10.2.7 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |
| Climate change: Warming and sea level rise, storm severity/frequency, sediment erosion, deposition | Sea level rise and increased storm severity and frequency would result in impacts on archaeological, architectural, and TCP resources. Increased storm frequency and severity would result in damage to and/or destruction of architectural properties. Sea level rise would increase erosion-related impacts on archaeological and architectural resources, while sea level rise would inundate | Sea level rise and storm severity/frequency would increase due to the effects of climate change. | See Sections 3.10.2.2.2, 3.10.2.2.3, and 3.10.2.2.4 for analysis. | See Sections 3.10.2.5, 3.10.2.6, and 3.10.2.7 and Section 3.10.2.1, Table 3.10-7 for analysis of impacts. | See Section 3.10.2.1, Table 3.10-7 for analysis of impacts. |

| Associated IPF: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | archaeological, architectural, and TCP resources. | | | | |

* Includes three constructed and permitted COP projects within the cultural resources viewshed GAA: Block Island, SFWF, and Vineyard Wind 1. The marine resources GAA only intersects SFWF, and the terrestrial GAA does not intersect any constructed and permitted COP projects.

## Recreation and Tourism

**Table E2-10. Summary of Activities and the Associated Impact-Producing Factors for Recreation and Tourism**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Anchoring | Constructed and permitted OSW COP projects are introducing an estimated 943 acres of anchoring in the GAA. Anchoring also occurs due to ongoing military, survey, commercial, and recreational activities. The presence of anchored vessels can increase navigation complexity for recreational vessels. Increased turbidity from anchoring can also briefly alter the behavior of species important to recreational fishing and sightseeing. However, impacts are anticipated to be temporary and localized. | Impacts from anchoring would continue and could increase due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. Modest growth in vessel traffic could increase the temporary, localized impacts of navigational hazards, increased turbidity levels, and potential for direct contact causing mortality of benthic resources. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| Light: Vessels | Nighttime vessel activity associated with permitted and built OSW COP projects is occurring during installation and O&M of various project components (cables, substation etc.). This source, along with light associated with other military, commercial, or construction vessel traffic, can temporarily affect coastal viewsheds when the addition of intrusive, modern lighting changes the physical environment (setting). | Anticipated modest growth in vessel traffic would result in some growth in the nighttime traffic of vessels with lighting. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| Light: Structures | Offshore buoys and towers emit low-intensity light. Onshore structures, including houses and ports, emit substantially more light on an ongoing basis. Constructed and permitted OSW COP projects are also introducing 81 lighted structures into the GAA. Lighted structures can result in impacts to impact recreation and tourism if recreation decisions are influenced by lighting, particularly if the light source affects uninterrupted nighttime skies or periods of darkness. | Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast but minimal offshore. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| New cable emplacement/ maintenance | Constructed and permitted OSW COP projects are introducing an estimated 462 miles of new offshore cable in the GAA. This and other | Cable maintenance or replacement of existing cables in the GAA would occur infrequently and would generate short-term disturbances. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | sources of cable activities can reduce recreational opportunities if individuals prefer to avoid the noise and disruption caused by installation; these disturbances would be localized and limited to emplacement corridors. | | | | |
| Noise: O&M | Noise impacts are expected from OSW and non-OSW O&M activity. However, sound pressure levels would be at or below ambient levels at relatively short distances from WTG foundations. | Not applicable. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| Noise: Pile driving | Noise from pile driving associated with permitted OSW COP projects is occurring during installation of foundations for offshore structures. Noise from pile driving also occurs periodically in nearshore areas when piers, bridges, pilings, and seawalls are installed or upgraded. These disturbances are temporary, local, and extend only a short distance beyond the work area. | No future activities were identified within the recreation and tourism GAA other than ongoing activities. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts during offshore activities. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| Noise: Cable laying/trenching | Noise from trenching/cable laying associated with permitted OSW COP projects may occur in the GAA. Offshore trenching occurs periodically in connection with non-OSW cable installation or sand and gravel mining. These disturbances are temporary, local, and extend only a short distance beyond the work area. | No future activities were identified within the recreation and tourism GAA other than ongoing activities. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| Noise: Vessels | Vessel noise occurs offshore and more frequently near ports and docks. Ongoing OSW and non-OSW activities that contribute to this sub-IPF consist of permitted and construction OSW COP projects, commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels. | Planned new barge routes and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts during offshore activities. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| Port utilization: Expansion | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance. The New Bedford Marine Commerce Terminal was upgraded by the port specifically to support the construction of OSW energy facilities. | Ports would need to perform maintenance and upgrade facilities over the next 35 years to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host larger deep draft vessels as they continue to increase in size. | **Offshore:** Existing ports used for staging and construction of planned future projects could influence recreational opportunities or access. However, these ports are primarily industrial in character and are not intended to support recreational activity as a primary use. If used secondarily for recreation, any port improvements could result in short-term delays and crowding during construction but would result in increased berths and amenities for recreational vessels, improved | **Offshore:** Existing ports in the GAA that would be used for Project staging and construction consist of the Port of Montauk, Port Jefferson, Port of Providence, Port of Davisville at Quonset Point, Point of Galilee, Port of New London, and New Bedford Marine Commerce Terminal. However, these ports are primarily industrial in character and are not intended to service recreational activity. Therefore, the Proposed Action would have a long-term **negligible** adverse impact on recreation and | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, Alternative G would have a **negligible** adverse impact on recreation and tourism due to port utilization within the GAA. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | navigational channels, or opportunities to separate recreational boating from commercial shipping in the long term. Because impacts to offshore recreation and tourism related to current marine industrial activities at existing ports would not experience significant changes, regardless of OSW industry development (BOEM 2016), only **negligible** adverse impacts on recreation and tourism could occur. | tourism due to port utilization within the GAA. Impacts of Alternatives C through F would be similar to the Proposed Action.<br>As previously noted, existing ports used for O&M of the Project could influence recreational opportunities or access. However, these ports are primarily industrial in character and are not intended to support recreational activity as a primary use. Because impacts to offshore recreation and tourism related to current marine industrial activities at existing ports would not experience significant changes, regardless of OSW industry development (BOEM 2016), negligible adverse impacts on recreation and tourism could occur. Impacts during decommissioning would be similar to the impacts during construction and installation. Although Alternatives C through F would reduce the number of WTGs and associated IACs, the impact would be **negligible** adverse.<br>Port activity would result in increased short-term construction traffic and long-term operational traffic to the No Action Alternative, which could coincide with recreational activity in the vicinity, depending on transportation type (e.g., vessels, rail, or road vehicle). However, activities related to the Proposed Action at port facilities would occur within the boundaries of existing ports or other repurposed industrial facilities where recreational users would not be expected to occur. Project activities at ports would be similar to those already taking place at these facilities and would be consistent with state and local agency guidelines regarding land use, access, noise and air quality, and other impacts on nearby neighborhoods. Alternatives C through F would reduce the number of WTGs and associated IACs, but Project impacts on this IPF would be similar to the Proposed Action, Therefore, the Proposed Action and Alternatives C through F when combined with past, present, and reasonably foreseeable activities would have **negligible** adverse cumulative impacts on recreation and tourism. | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | **Onshore:** Impacts to onshore recreation and tourism related to current marine industrial activities at existing ports would not result in significant changes, regardless of OSW industry development (BOEM 2016). Therefore, impacts would be **negligible** adverse. | **Onshore:** The proposed O&M facility (located in the Port of Brooklyn, Port of Davisville at Quonset Point, Port of Galilee, Port Jefferson, or Port of Montauk) would be located within an existing industrial port. No new building construction would occur at the Port of Galilee or Port of Brooklyn; use of these ports is assumed to be limited to existing facilities maintained by the ports. However, a new building with up to 1,000 square feet of office space and up to 11,000 square feet of equipment storage space could be constructed at the Port of Davisville at Quonset Point or the Port of Montauk. A BOEM study suggests that impacts on recreation and tourism related to current marine industrial activities at existing ports would not experience significant long-term changes, regardless of OSW industry development (BOEM 2016). However, the study notes that although the Atlantic Coast already possesses the necessary infrastructure to support OSW, the industry is still evolving (BOEM 2016), and communication, flexibility, and scalability are needed to ensure port selection would not impact tourism or recreation. Based on BOEM's findings, **negligible** temporary adverse impacts to recreation or tourism activities from port use are anticipated during construction.<br>O&M facilities and activity would be indistinguishable from other industrial or commercial businesses and maritime activities that typically occur at proposed port locations. As these ports do not provide recreation as a primary service, O&M would have **negligibl**e adverse impacts on onshore recreation and tourism.<br>Project facilities and port activity would be indistinguishable from other industrial or commercial businesses and maritime activities that typically occur at proposed port locations. As these ports do not provide recreation as a primary service, the Proposed Action and Alternatives C through F when combined with past, present, and reasonably foreseeable projects would result in | **Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, Alternative G would have a **negligible** adverse impact on recreation and tourism due to port utilization within the GAA. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | temporary **negligible** adverse cumulative impacts to onshore recreation and tourism. | |
| Port utilization: Maintenance/ Dredging | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. Periodic maintenance is necessary for harbors within the GAA. | Ongoing maintenance and dredging of harbors within the GAA would continue as needed. No specific projects are known. | See Port Utilization: Expansion for analysis of offshore and onshore impacts. | See Port Utilization: Expansion for analysis of offshore and onshore impacts. | See Port Utilization: Expansion for analysis of offshore and onshore impacts. |
| Presence of structures: Allisions | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA. An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. The presence of OSW structures increases the GAA's navigational complexity, thereby increasing the risk of allision or collision. However, WTG spacing is anticipated to reduce, but not eliminate, navigational complexity during the operations phases of the projects. | Vessel allisions with non-OSW stationary objects should not increase meaningfully without a substantial increase in vessel congestion. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts during offshore activities. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| Presence of structures: Entanglement, gear loss, gear damage | Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. Additionally, constructed and permitted OSW COP projects are introducing 81 structures into the GAA that can increase risk of entanglement by recreational fishermen. | No future activities were identified within the recreation and tourism GAA other than ongoing activities. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts during offshore activities. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| Presence of structures: Fish aggregation and habitat conversion | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA. Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly flat seascape. Structure-oriented fishes are attracted to these locations. Recreational and commercial fishing can occur near these aggregation locations, although recreational fishing is more popular because commercial mobile fishing gear is more likely to snag on structures. | Reasonably foreseeable activities (non–OSW) would not result in additional offshore structures. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts during offshore activities. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| Presence of structures: Navigation hazard | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA. Vessels need to navigate around structures to avoid allisions, especially in nearshore areas. This navigation becomes more complex when multiple vessels must navigate around a structure because vessels need to avoid both the structure and each other. The presence of OSW structures increases the GAA's | Vessel traffic, overall, is not expected to meaningfully increase over the next 35 years. The presence of navigation hazards is expected to continue at or near current levels. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts during offshore activities. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | navigational complexity, thereby increasing the risk of allision or collision. However, WTG spacing is anticipated to reduce, but not eliminate, navigational complexity during the operations phases of the projects. | | | | |
| Presence of structures: Space use conflicts | Currently, the offshore area is occupied by marine trade, stationary and mobile fishing, and survey activities. Constructed and permitted OSW COP projects are also introducing 81 structures into the GAA. The presence of OSW structures increases the GAA's navigational complexity. The attraction of artificial reef effects also increases vessel congestion and the risk of allision, collision, and spills near structures. However, WTG spacing is anticipated to reduce, but not eliminate, space-use conflicts during the operations phases of the projects. | Reasonably foreseeable activities (non–OSW) would not result in additional offshore structures. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts during offshore activities. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| Presence of structures: Viewshed | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA, which are visible from some coastal locations in New York, Connecticut, Rhode Island, and Massachusetts. | Non-OSW structures that could be viewed in conjunction with the offshore components of the Project would be limited to met towers. Marine activity would also occur within the marine viewshed. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |
| Traffic: Vessels | The GAA would continue to have numerous ports, and the extensive OSW and non-OSW marine traffic related to shipping, fishing, and recreation would continue to be important to the region's economy. | New vessel traffic in the GAA would be generated by proposed barge routes and dredging demolition sites over the next 35 years. Marine commerce and related industries would continue to be important to the economy. | See Section 3.18.2.2.2 for analysis. | See Section 3.18.2.3 and Section 3.18.2.1, Table 3.18-2 for analysis of impacts. | See Section 3.18.2.1, Table 3.18-2 for analysis of impacts. |

* Includes three constructed and permitted COP projects within the recreation and tourism GAA: Block Island, SFWF, and Vineyard Wind 1.

## Visual Resources

No IPFs with solely negligible impacts were identified.

**Table E2-11. Summary of Activities and the Associated Impact-Producing Factors for Visual Resources**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Light: Vessels | Nighttime vessel activity associated with permitted and built OSW COP projects is occurring during installation and O&M of various project components (cables, substation, etc.). This light source, along with light associated with other military, commercial, or construction vessel traffic, can | Future activities with the potential to result in vessel lighting impacts consist of construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries | See Section 3.20.2.2.2 for analysis. | See Section 3.20.2.3 and Section 3.20.2.1, Table 3.20-1 for analysis. | See Section 3.20.2.1, Table 3.20-1 for analysis. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | temporarily affect coastal viewsheds when the addition of intrusive, modern lighting changes the physical environment (setting). Offshore construction activities that require increased vessel traffic, construction vessels stationed offshore, and construction area lighting for prolonged periods can cause more sustained and significant visual impacts. | use and management; and oil and gas activities. Light pollution from vessel traffic would continue at the current intensity along the Northeast coast, with a slight increase due to population increase and development over time. | | | |
| Light: Structures | Constructed and permitted OSW COP projects are introducing 81 lighted structures into the GAA. The construction of new structures that introduce new light sources can result in impacts, particularly if the light source affects uninterrupted nighttime skies or periods of darkness. Any tall structure (e.g., commercial building, radio antenna, large satellite dish) requiring nighttime hazard lighting to prevent aircraft collision can cause these types of impacts. | Light from onshore structures is expected to gradually increase in line with human population growth along the coast. This increase is expected to be widespread and permanent near the coast but minimal offshore. | See Section 3.20.2.2.2 for analysis. | See Section 3.20.2.3 and Section 3.20.2.1, Table 3.20-1 for analysis. | See Section 3.20.2.1, Table 3.20-1 for analysis. |
| Presence of structures | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA, which are visible from some coastal locations in New York, Connecticut, Rhode Island, and Massachusetts. | Non-OSW structures that could be viewed would be limited to met towers. Marine activity would also occur within the viewshed of the GAA. | See Section 3.20.2.2.2 for analysis. | See Section 3.20.2.3 and Section 3.20.2.1, Table 3.20-1 for analysis. | See Section 3.20.2.1, Table 3.20-1 for analysis. |

* Includes three constructed and permitted COP projects within the visual resources GAA: Block Island, SFWF, and Vineyard Wind 1.

## Commercial Fisheries and For-Hire Recreational Fishing

No IPFs with solely negligible impacts were identified.

**Table E2-12. Summary of Activities and the Associated Impact-Producing Factors for Commercial Fisheries and For-Hire Recreational Fishing**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/hazmat | Constructed and permitted OSW COP projects can accidentally release an estimated 900,000 gallons of fuel, oils, or other hazardous materials in the GAA. See Table E1-4 for a quantitative analysis of these risks. Ongoing releases are frequent and chronic. Accidental releases and discharges of fuels and fluids that reduce water quality could have a physiological or behavioral impact on some species targeted by commercial and for-hire recreational fisheries in the GAA. | Gradually increasing vessel traffic over the next 35 years would increase the risk of accidental releases. Future accidental releases from offshore vessel usage, spills, and consumption would likely continue on a similar trend to ongoing activities. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Section 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | However, all vessels would comply with USCG requirements and BSEE regulations for the prevention and control of oil and fuel spills. | | | | |
| Accidental releases: Trash and debris | Constructed and permitted OSW COP projects can potentially generate operational waste, including bilge and ballast water, sanitary and domestic wastes, and trash and debris in the GAA. Trash and debris could also be accidentally discharged through fisheries use, dredged material ocean disposal, marine minerals extraction, marine transportation, navigation and traffic, survey activities and cables, and lines and pipeline laying. Accidental releases of trash and debris are expected to be low probability events. | No future activities were identified within the GAA other than ongoing activities. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Section 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| Anchoring | Constructed and permitted OSW COP projects are introducing an estimated 944 acres of anchoring in the GAA. Impacts from anchoring also occur due to other ongoing military, survey, commercial, and recreational activities. The short-term, localized impact to this resource is the presence of a navigational hazard (anchored vessel) to fishing vessels. | Impacts from anchoring could occur on a semiregular basis over the next 35 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. Anchoring could pose a temporary (hours to days), localized (within a few hundred meters of the anchored vessel) navigational hazard to fishing vessels. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| Light | Impacts include light associated with military, commercial, or OSW and non-OSW construction vessel traffic. Ocean vessels have an array of lights, including navigational lights and deck lights. Offshore buoys and towers emit low-intensity light. Onshore structures, including houses and ports, emit substantially more light on an ongoing basis. Light can attract finfish and invertebrates, potentially affecting distributions in a highly localized area. Light may also disrupt natural cycles, e.g., spawning, possibly leading to short-term impacts. | Future activities with the potential to result in lighting impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Light pollution from vessel traffic would continue at the current intensity along the Northeast coast, with a slight increase due to population increase and development over time. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| New cable emplacement/ maintenance | Constructed and permitted OSW COP projects are introducing an estimated 498 miles of new offshore cable in the GAA. This and other non-OSW cable activities can disturb the seafloor, increase suspended sediment, and cause temporary displacement of fishing vessels. These disturbances would be local and limited to the emplacement corridor. | Future new cables and cable maintenance would occasionally disturb the seafloor and cause temporary displacement in fishing vessels and increases in suspended sediment, resulting in local, short-term impacts. If the cable routes enter the GAA for this resource, short-term disruption of fishing activities would be expected. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Noise: Construction, trenching, O&M | Noise from onshore construction associated with permitted OSW COP projects is occurring during installation of various project components (cables, substation etc.). Other noise from construction occurs frequently in coastal habitats in populated areas in New England and the Mid-Atlantic but infrequently offshore. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. Infrequent offshore trenching could occur in connection with cable installation. These disturbances are temporary, local, and extend only a short distance beyond the emplacement corridor. Low levels of elevated noise from operational WTGs likely have low to no impacts on fish and no impacts at a fishery level.<br>Noise is also created by O&M of marine minerals extraction, which has small local impacts on fish, but likely no impacts at a fishery level. | Noise from construction near shorelines is expected to gradually increase in line with human population growth along the coast of the GAA for this resource. Noise from dredging and sand and gravel mining could occur. New or expanded marine minerals extraction could increase noise during their O&M over the next 35 years. Impacts from construction, operations, and maintenance would likely be small and local on fish and not seen at a fishery level. Periodic trenching would be needed for repair or new installation of underground infrastructure. These disturbances would be temporary, local, and extend only a short distance beyond the emplacement corridor. Impacts of trenching noise on commercial fish species are typically less prominent than the impacts of the physical disturbance and sediment suspension. Therefore, fishery-level impacts are unlikely. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| Noise: G&G | Noise from G&G and scientific surveys associated with permitted OSW COP projects may occur in the GAA. Ongoing site characterization surveys and scientific surveys produce noise around sites of investigation. These activities can disturb fish and invertebrates in the immediate vicinity of the investigation and can cause temporary behavioral changes. The extent depends on equipment used, noise levels, and local acoustic conditions. | Site characterization surveys, scientific surveys, and exploratory oil and gas surveys are anticipated to occur infrequently over the next 35 years. Seismic surveys used in oil and gas exploration create high-intensity impulsive noise to penetrate deep into the seafloor, potentially resulting in injury or mortality to finfish and invertebrates in a small area around each sound source and short-term stress and behavioral changes to individuals over a greater area. Site characterization surveys typically use sub-bottom profiler technologies that generate less intense sound waves more similar to common deep-water echosounders. The intensity and extent of the resulting impacts are difficult to generalize but are likely local and temporary. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| Noise: Pile driving | Noise from pile driving associated with permitted OSW COP projects is occurring during installation of foundations for offshore structures. Noise from pile driving also occurs periodically in nearshore areas when ports or marinas, piers, bridges, pilings, and seawalls are installed or upgraded. Noise transmitted through water and/or the seafloor can cause | No future activities were identified within the GAA other than ongoing activities. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | injury and/or mortality to finfish and invertebrates in a small area around each pile and can cause short-term stress and behavioral changes to individuals over a greater area, leading to temporary, local impacts on commercial fisheries and for-hire recreational fishing. The extent depends on pile size, hammer energy, and local acoustic conditions. | | | | |
| Noise: Vessels | Vessel noise is anticipated to continue at levels similar to current levels. While OSW and non-OSW vessel noise could have some impact on behavior, it is likely limited to brief startle and temporary stress responses. Ongoing activities that contribute to this sub-IPF consist of permitted and construction OSW COP projects, commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. | Planned new barge route and dredging disposal sites would generate vessel noise when implemented. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| Port utilization: Expansion | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance, including dredging. Port utilization is expected to increase over the next 35 years. | Ports would need to perform maintenance and upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host larger deep draft vessels as they continue to increase in size. Port utilization is expected to increase over the next 35 years, with increased activity during construction. The ability of ports to receive the increase in vessel traffic could require port modifications, such as channel deepening, leading to local impacts on fish populations.<br>Port expansions could also increase vessel traffic and competition for dockside services, which could affect fishing vessels. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| Presence of structures: Navigation hazard and allisions | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Other structures that pose potential navigation hazards consist of buoys and shoreline developments such as docks and ports. An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. Two types of allisions occur: drift and powered. A drift allision generally occurs when a vessel is powered down due to operator choice or power failure. A powered allision generally occurs when an operator fails to adequately | No known reasonably foreseeable structures are proposed to be located in the GAA that could affect commercial fisheries. Vessel allisions with non-OSW stationary objects should not increase meaningfully without a substantial increase in vessel congestion. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | control their vessel movements or is distracted. The presence of OSW structures increases the GAA's navigational complexity, thereby increasing the risk of allision or collision. However, WTG spacing is anticipated to reduce, but not eliminate, navigational complexity during the operations phases of the projects. | | | | |
| Presence of structures: Entanglement, gear loss, gear damage | Commercial and recreational fishing gear is periodically lost due to entanglement with existing buoys, pilings, hard protection, and other structures. Additionally, constructed and permitted OSW COP projects are introducing 83 structures into the GAA that can increase risk of entanglement. The lost gear, moved by currents, can disturb habitats and potentially harm individuals, creating small, localized, short-term impacts on fish, but likely no impacts at a fishery level. | No future activities were identified within the GAA other than ongoing activities. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| Presence of structures: Habitat conversion and fish aggregation | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Structures, including tower foundations, scour protection around foundations, and various means of hard protection atop cables, create uncommon relief in a mostly sandy seascape. A large portion is homogeneous sandy seascape, but there is some other hard and/or complex habitat. Structures are periodically added, resulting in the conversion of existing soft-bottom and hard-bottom habitats to the new hard-structure habitat. Structure-oriented fishes are attracted to these locations. These impacts are local and can be short term to permanent. Fish aggregation could be considered adverse, beneficial, or neither. Commercial and for-hire recreational fishing can occur near these structures. For-hire recreational fishing is more popular because commercial mobile fishing gear is more likely to snag on structures. | New cables, installed incrementally in the GAA over the next 20 to 35 years, would likely require hard protection atop portions of the route (see the New cable emplacement/maintenance IPF above). Any new towers, buoys, or piers would also create uncommon relief in a mostly flat seascape. Structure-oriented species could be attracted to these locations. Structure-oriented species would benefit (Claisse et al. 2014; Smith et al. 2016). This could lead to more and larger structure-oriented fish communities and larger predators opportunistically feeding on the communities as well as increased private and for-hire recreational fishing opportunities. Soft bottom is the dominant habitat type in the region, and species that rely on this habitat would not likely experience population-level impacts (Greene et al. 2010; Guida et al. 2017). These impacts are expected to be local and could be long term. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| Presence of structures: Migration disturbances | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Human structures in the marine environment (e.g., shipwrecks, artificial reefs, buoys, and oil platforms) can attract finfish and invertebrates that approach the structures during their migrations. This could slow | The infrequent installation of future new structures in the marine environment over the next 35 years could attract finfish and invertebrates that approach the structures during their migrations. This could tend to slow migrations. However, temperature is expected to be a bigger driver of habitat | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | species migrations. However, temperature is expected to be a bigger driver of habitat occupation and species movement than structure (Secor et al. 2018). There is no evidence to suggest that structures pose a barrier to migratory animals. | occupation and species movement (Secor et al. 2018). Migratory animals would likely be able to proceed from structures unimpeded. Therefore, fishery-level impacts are not anticipated. | | | |
| Presence of structures: Space use conflicts | Currently, the offshore area is occupied by marine trade, stationary and mobile fishing, and survey activities. Constructed and permitted OSW COP projects are also introducing 83 structures into the GAA. The presence of OSW structures increases the GAA's navigational complexity. The attraction of artificial reef effects also increases vessel congestion and the risk of allision, collision, and spills near structures. However, WTG spacing is anticipated to reduce, but not eliminate, space-use conflicts during the operations phases of the projects. | No known reasonably foreseeable structures are proposed for location in the GAA that could affect commercial fisheries and for-hire recreational fishing. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| Presence of structures: Cable infrastructure | The existing offshore cable infrastructure supports the economy by transmitting electric power and communications between the mainland and islands. Seven submarine cable corridors cross cumulative lease areas. Shoreline developments are ongoing and consist of docks; ports; and other commercial, industrial, and residential structures. Additionally, constructed and permitted OSW COP projects are introducing an estimated 462 miles of new offshore cable in the GAA. Increased presence of cables and cable protection may increase the risk of gear loss or entanglement. | No future activities were identified within the GAA for this resource other than ongoing activities. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| Traffic: Vessels and vessel collisions | The GAA would continue to have numerous ports, and the extensive OSW and non-OSW marine traffic related to shipping, fishing, and recreation would continue to be important to the region's economy. The region's substantial marine traffic could result in occasional collisions. Vessels need to navigate around structures to avoid allisions. When multiple vessels need to navigate around a structure, then navigation is more complex as the vessels need to avoid both the structure and each other. The risk for collisions is ongoing but infrequent. | New vessel traffic in the GAA would consistently be generated by proposed barge routes and dredging demolition sites. Marine commerce and related industries would continue to be important to the regional economy. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Climate change | Impacts to commercial fisheries and for-hire recreational fishing are expected to result from climate change events such as increased magnitude or frequency of storms, shoreline changes, ocean acidification, and water temperature changes. Risks to fisheries associated with these events include habitat/distribution shifts, disease incidence, and risk of invasive species. If these risk factors result in a decrease in catch and/or an increase in fishing costs (e.g., transiting time), the profitability of businesses engaged in commercial fisheries and for-hire recreational fishing would be adversely affected. While climate change is predicted to have adverse impacts on the distribution and/or productivity of some stocks targeted by commercial fisheries and for-hire recreational fishing, other stocks could be beneficially affected.<br>The economies of communities reliant on marine species that are vulnerable to the effects of climate change could be adversely affected. If the distribution of important stocks changes, it could affect where commercial and for-hire recreational fisheries are located. Furthermore, coastal communities with fishing businesses that have infrastructure near the shore could be adversely affected by sea level rise. | No future activities were identified within the GAA for this resource other than ongoing activities. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |
| Fisheries management activities | Commercial and recreational regulations for finfish and shellfish implemented and enforced by NMFS and coastal states affect how the commercial and for-hire recreational fisheries operate. Commercial and recreational for-hire fisheries are managed by FMPs, which are established to manage fisheries to avoid overfishing through catch quotas, special management areas, and closed area regulations. These can reduce or increase the size of available landings to commercial and for-hire recreational fisheries. For example, ongoing fishing restrictions designed to rebuild depleted stocks in the Northeast Multispecies (large-mesh) fishery would continue to reduce landings in that fishery. | Reasonably foreseeable fishery management actions include measures to reduce the risk of interactions between fishing gear and the NARW by 60% (McCreary and Brooks 2019). This would likely have a **major** adverse impact on fishing effort in the lobster and Jonah crab fisheries in the GAA for this resource. As discussed in Karp et al. (2019), changing climate and ocean conditions and the resultant effects on species distributions and productivity can have significant effects on management decisions, such as allocation, spatiotemporal closures, stock status determinations, and catch limits. | See Section 3.9.2.2.2 for analysis of offshore impacts. | See Sections 3.9.2.3 and 3.9.2.4 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. | See Sections 3.9.2.5 and Section 3.9.2.1, Table 3.9-23 for analysis of offshore impacts. |

* Includes all constructed and permitted COP projects within the commercial fisheries and for-hire recreational fishing GAA: Block Island, SFWF, Vineyard Wind 1, and Coastal Virginia Offshore Wind.

## Land Use and Coastal Infrastructure

**Table E2-13. Summary of Activities and the Associated Impact-Producing Factors for Land Use and Coastal Infrastructure**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases: Fuel/fluids/hazmat | Various ongoing OSW and non-OSW onshore and coastal construction projects include the use of vehicles and equipment that contain fuel, fluids, and hazardous materials that could be released. These impacts, however, would generally be localized and short term. | Ongoing onshore construction projects involving vehicles and equipment that use fuel, fluids, or hazardous materials could result in an accidental release. Intensity and extent would vary, depending on the size, location, and materials involved in the release. | See Section 3.14.2.2.2 for analysis. | See Sections 3.14.2.3 and 3.14.2.1, Table 3.14-1 for analysis of impacts. | See Section 3.14.2.1, Table 3.14-1 for analysis of impacts. |
| EMFs | Constructed and permitted OSW COP projects can generate EMF and substrate heating effects. EMFs also continuously emanate from existing telecommunication and electrical power transmission cables. New cables generating EMFs are infrequently installed in the GAA. The extent of impacts is likely less than 50 feet (15.2 m) from the cable, and the intensity of impacts on coastal habitats is likely undetectable. | No future activities were identified within the GAA for land use and coastal infrastructures other than ongoing activities. | The onshore transmission lines used to connect power generated by future OSW projects to the electrical grid would generate detectable EMF effects within a short distance of cable corridors. Most, if not all, future onshore transmission cables would run belowground in buried cable ducts, reducing EMF exposure relative to aboveground electrical infrastructure. Based on modeled EMF levels for currently planned projects (Exponent 2018, 2020), typical EMF levels at approximately 3 feet (1 meter) immediately above the buried cable would range from 73 to 300 mG. Field strength would diminish rapidly with distance, decreasing to near 0 mG within 25 to 50 feet of the cable centerline. These potential effects must be placed in context with typical levels of EMF exposure experienced in everyday life. The National Institutes of Health (NIH 2002) determined that approximately 95% of the U.S. population has an average daily EMF exposure of approximately 4 mG from electrical systems and devices at home and work. Localized EMF levels in proximity to electrical power infrastructure are considerably higher. Typical magnetic fields within 50 feet of power distribution lines range from 10 to 20 mG for main feeders and 3 to 10 mG for laterals under typical loads, reaching as high as 40 to 70 mG under peak loads depending on the amount of current being carried (NIH 2002).<br>Anticipated onshore EMF from OSW energy transmission cables would be comparable to, if not lower than, baseline EMF levels | **Offshore:** There would be no EMF produced during construction of the offshore Project structures.<br>Offshore elements of the Proposed Action such as the WTGs, IAC, and OSS-link cable would generate EMF during operation. The cables produce a magnetic field, both perpendicularly and in a lateral direction around the cables. The calculated magnetic field at a height of 3.3 feet (1 m) above the seafloor is highest directly above the buried cables (IACs, 17 mG; RWECs, 41 mG; and RWEC landfall cables, 39 mG) and decreases rapidly with distance. EMF is reduced to less than 6 mG within 30 feet of the IACs, RWECs, and RWEC landfall cables. All calculated field levels are well below the ICNIRP reference level of 2,000 mG and the ICES exposure reference level of 9,040 mG for exposure of the general public. Therefore, effects would be **negligible** adverse. Impacts would be lower, but still similar, for Alternatives C through F due to the reduction of the number of WTGs and possible reduction of miles of IAC.<br>Reasonably foreseeable future actions would also generate offshore EMF due to the use of similar Project components. However, it is anticipated that reasonably foreseeable future actions would also use similar construction and operations techniques, which includes shielding and protecting cables that are laid directly on the seafloor. Shielded electrical transmission cables do not directly emit electrical fields into surrounding areas but are surrounded by magnetic fields that can cause induced electrical fields in | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. There would be no EMF produced during construction of the offshore Project structures.<br>Operational effects would be **negligible** adverse. Impacts would be lower, but still similar, for Alternative G due to the reduction of the number of WTGs and possible reduction of miles of IAC.<br>Due to the rapid dissipation of EMFs surrounding the cables and incorporation of protection measures, there would be a **negligible** adverse cumulative impact on land use and coastal infrastructure for Alternative G. Impacts would be lower, but still similar, for Alternative G due to the reduction of the number of WTGs and possible reduction of miles of IAC. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
| --- | --- | --- | --- | --- | --- |
| | | | generated by existing aboveground electrical infrastructure. Future OSW projects would likely generate EMF levels similar to those for the Project. International Commission on Non-Ionizing Radiation Protection (ICNIRP) and International Committee on Electromagnetic Safety (ICES) guidance set exposure levels between 2,000 and 9,040 mG for the general population, although exact levels vary from state to state. The addition of wind energy transmission cables would result in slightly elevated onshore EMF levels. However, EMF levels decrease very rapidly with distance from the cables. For an 880-MW transmission cable, peak EMF would be 73 mG at the cable but would decrease to 2 mG at 25 feet from the cable. This is well below international EMF standards. The presence of slightly elevated levels of EMF from future OSW activities would have no effect on land use and coastal infrastructure because elevated EMF would not alter land use patterns, change land uses, or have any other effect on land use and coastal infrastructure. On this basis, the effects of EMF on land use under the No Action Alternative would be long term **negligible** adverse, as there would be no effect on land use and coastal infrastructure. | moving water. Due to the rapid dissipation of EMFs surrounding the cables and incorporation of protection measures, there would be a **negligible** adverse cumulative impact on land use and coastal infrastructure for the Proposed Action and Alternatives C through F. Impacts would be lower, but still similar, for Alternatives C through F due to the reduction of the number of WTGs and possible reduction of miles of IAC. | |
| | | | | **Onshore:** There would be no EMF produced during construction of the onshore Project structures.<br>Between the TJBs and OnSS, the onshore transmission cables would be installed in a double-circuit underground duct bank. Modeling of the magnetic field levels associated with the operation of these cables calculates the magnetic field at peak loading directly over the duct banks at 73 mG or lower for the maximum 880-MW capacity of the RWF. This is well below the ICNRIP reference level of 2,000 mG and the ICES exposure reference level of 9,040 mG for the general public (Exponent 2020). Lower magnetic fields would be produced if the power generated by the RWF is less than 880 MW.<br>Based on modeled EMF levels for the Proposed Action (Exponent 2020), typical EMF levels at approximately 3 feet (1 m) immediately above the buried cable would be a maximum of 73 mG. Field strength would diminish rapidly with distance, decreasing to near 0 mG within 25 to 50 feet of the cable centerline. These potential effects must be placed in context with typical levels of EMF exposure experienced in everyday life. The NIH (2002) determined that approximately 95% of the U.S. population has an average daily EMF exposure of approximately 4 mG from electrical systems and devices at home and work. Localized EMF levels in proximity to electrical power infrastructure are considerably higher. Typical magnetic fields within 50 feet of power distribution lines range from 10 to 20 mG for main feeders and | **Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. There would be no EMF produced during construction of the Alternative G onshore Project structures.<br>There would be no impact on land use and coastal infrastructure due to EMFs from O&M of onshore Project facilities. Decommissioning would result in no EMF impacts, similar to construction. Therefore, there would be a **negligible** adverse EMF impact on land use and coastal infrastructure from O&M and decommissioning of onshore elements of Alternative G.<br>Reasonably foreseeable future actions would likely generate EMF levels similar to those for the Proposed Action. On this basis, the cumulative effects of EMF on land use under Alternative G would be **negligible** adverse as there would be no effect on land use and coastal infrastructure and Alternative G has identical onshore facilities and activities. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | 3 to 10 mG for laterals under typical loads, reaching as high as 40 to 70 mG under peak loads, depending on the amount of current being carried (NIH 2002). Therefore, the relative level of EMF from the onshore duct bank would be low compared to other electrical infrastructure.<br>The underground transmission cables onshore would not be a direct source of any electric field aboveground due to cable construction, duct bank, and burial underground (VHB 2023b). As EMFs would remain well below established thresholds and there would be no direct source of aboveground EMFs, it is anticipated that there would be no impact on land use and coastal infrastructure due to EMFs from O&M of onshore Project facilities. Decommissioning would result in no EMF impacts, similar to construction. Therefore, there would be a **negligible** adverse EMF impact on land use and coastal infrastructure from O&M and decommissioning of onshore elements of the Proposed Action and Alternatives C through F.<br>Reasonably foreseeable future actions would likely generate EMF levels similar to those for the Proposed Action. On this basis, the cumulative effects of EMF on land use under all Project alternatives would be **negligible** adverse as there would be no effect on land use and coastal infrastructure and the Proposed Action and Alternatives C through F have identical onshore facilities and activities. | |
| Light: Structures | Various OSW and non-OSW ongoing onshore and coastal construction projects have nighttime activities, as well as existing structures, facilities, and vehicles, that would use nighttime lighting. All construction and operational impacts from land disturbance would be regulated through local land use and zoning regulations and would therefore comply with applicable laws. | Ongoing onshore construction projects involving nighttime activity could generate nighttime lighting. Intensity and extent would vary, depending on the location, type, direction, and duration of nighttime lighting. | See Section 3.14.2.2.2 for analysis. | See Section 3.14.2.3 and Section 3.14.2.1, Table 3.14-1 for analysis of impacts. | See Section 3.14.2.1, Table 3.14-1 for analysis of impacts. |
| New cable emplacement/maintenance | Onshore OSW and non-OSW-related buried transmission cables are present in the area near the Project onshore and offshore improvements. Onshore activities would only | No known proposed onshore structures are reasonably foreseeable and proposed to be located in the GAA for land use and coastal infrastructure. | See Section 3.14.2.2.2 for analysis of onshore impacts. Offshore cable activities would not impact onshore land use or infrastructure. | See Section 3.14.2.3 and Section 3.14.2.1, Table 3.14-1 for analysis of onshore impacts. Offshore cable activities would not impact onshore land use or infrastructure. | See Section 3.14.2.1, Table 3.14-1 for analysis of onshore impacts. Offshore cable activities would not impact onshore land use or infrastructure. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | occur where permitted by local land use authorities, which would avoid long-term land use conflicts. | | | | |
| Noise | Noise from activities associated with permitted OSW COP projects and other non-OSW projects may occur in the GAA. Ongoing noise from construction occurs frequently near the shores of populated areas in New England and the Mid-Atlantic region but infrequently offshore. Noise from construction near shorelines is expected to gradually increase over the next 30 years in line with human population growth along the coast of the GAA. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. | No future activities were identified within the GAA other than ongoing activities. | See Section 3.14.2.2.2 for analysis. | See Section 3.14.2.3 and Section 3.14.2.1, Table 3.14-1 for analysis of impacts. | See Section 3.14.2.1, Table 3.14-1 for analysis of impacts. |
| Port utilization: Expansion | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance. The MCT at the Port of New Bedford is a completed facility developed by the port specifically to support the construction of OSW facilities. | Ports would need to perform maintenance and upgrade facilities to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host larger deep draft vessels as they continue to increase in size. | Various ports would be improved to support future OSW projects (see EIS Appendix E). These improvements would occur within the boundaries of existing port facilities, would be similar to existing activities at the existing ports, and would support state strategic plans and local land use goals for the development of waterfront infrastructure. Therefore, ports would experience long-term beneficial impacts such as greater economic activity and increased employment due to demand for vessel maintenance services and related supplies; vessel berthing, loading and unloading; warehousing and fabrication facilities for OSW components; and other business activity related to OSW. State and local agencies would be responsible for minimizing the potential adverse impacts of these future port expansions by managing port resources and traffic control to ensure continued access to ports and adjacent land uses. There could be increased traffic and noise associated with increased port use that could impact land uses by increasing congestion and noise. However, all traffic, noise, and other adverse impacts would be under regulatory thresholds as ports would be required to comply with local land use and zoning regulations. On this basis, the effects of port utilization on land use under | **Offshore:** Land uses impacted by the construction of offshore components would include chosen port facilities used for shipping, storing, and fabricating Project components and for crew transfer, cargo logistics, and storage. Revolution Wind would use one or more ports to offload shipments of components, prepare them for installation, and load components onto vessels for delivery and installation. Selected ports could require improvements or upgrades to meet Project needs (see Table 3.3.10-1 of the COP), but no specific port improvements have been proposed as part of the Proposed Action. The COP states that to the extent that upgrades or modifications at an existing port facility could occur, Revolution Wind expects that those upgrades or modifications would serve to support the U.S. OSW industry in general. This is especially true as a number of states continue to procure, support, and fund such development. Thus, whether or not upgrades are required, port facilities are expected to serve multiple OSW projects and potentially also OSW-related and other maritime industries.<br>BOEM (2016) analyzed potential impacts to ports that could require upgrades to accommodate OSW projects or that are in the process of completing upgrades in | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Alternative G would slightly reduce impacts to port utilization due to reduction of the number of WTGs and possible reduction of miles of IAC. However, impacts would be similar to the Proposed Action: long term **minor** beneficial and a **negligible** adverse. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | the No Action Alternative would be long term **negligible** adverse. | anticipation of increased port use associated with OSW projects. BOEM noted that land use and transportation impacts primarily include land-based space conflicts with current or planned uses of adjacent areas and landside traffic delays or conflicts associated with construction. BOEM (2016) also identified potential water-based space conflicts with other uses of port waterways such as dredging, pile driving, and fill placement. The ports under consideration for construction staging are industrial in character, designated by local zoning and land use plans for heavy industrial activity, and typically adjacent to other industrial or commercial land uses and major transportation corridors. Therefore, it is expected that port improvements or upgrades would be subject to local zoning and land use regulations and that any upgrades to ports would undergo independent permitting and regulatory compliance processes.<br><br>The development of an OSW industry on the Mid-Atlantic OCS could incentivize the expansion or improvement of regional ports to support planned and future projects; however, no specific port improvements are identified as part of the Project. All future port improvements would be subject to independent environmental permitting and regulatory review and would be consistent with local land use and zoning regulations. As such, any future port improvements supporting OSW development would be consistent with, and therefore would not hinder, other nearby land use or use of coastal infrastructure. Overall, construction and installation of offshore components would have minor beneficial impacts to land use and coastal infrastructure by supporting designated uses at ports and supporting port improvements and/or redevelopment. Improvements such as road widening and signalization would provide transportation flow benefits over the long term. Because port expansion and upgrades are not part of the Proposed Action and would undergo separate permitting and regulatory review, | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
| --- | --- | --- | --- | --- | --- |
| | | | | there would be a negligible adverse port utilization impact on land use and coastal infrastructure from construction and installation of offshore elements of the Proposed Action. Alternatives C through F would slightly reduce impacts to port utilization due to reduction of the number of WTGs and possible reduction of miles of IAC. However, impacts would be similar to the Proposed Action: **negligible** adverse.<br>Offshore O&M facilities would include the RWEC, IAC, OSS interconnection cable, and OSS electrical components. While these offshore components would tie into onshore Project components that could affect land use, the offshore activities and facilities themselves would not directly impact land use. Offshore facilities that tie into onshore facilities could result in increased activity within any of the listed onshore port areas zoned for business and industrial uses. However, this would reinforce the designated land use and provide a source of investment in the coastal infrastructure. Activities at ports, as in the preceding paragraph, would be consistent with the existing and designated uses at other ports and would comply with local zoning and land use regulations. Therefore, there would be a long-term **minor** beneficial and a **negligible** adverse port utilization impact on land use and coastal infrastructure from O&M and decommissioning of offshore elements of the Proposed Action. Impacts would be similar for Alternatives C through F, although slightly reduced, so the impact determination would be the same as the Proposed Action.<br>Port upgrades and vessel activity associated with the Proposed Action could result in incremental impacts through an increase in economic and employment opportunities as well as reduced port access, increased delays and congestion, or increased collision risk. Project port activity and upgrades (via dredging and in-water work) could also coincide with other forecasted projects. Quonset Point is scheduled to undergo remediation at the former NIKE Battery PR-58 and Disaster Village Training Area in 2021. | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | In late 2020, the Rhode Island congressional delegation and the general treasurer joined the Rhode Island Department of Environmental Management in launching a $5.2 million project to make improvements at the Port of Galilee. The project would be located at the North Bulkhead section of the port where heavy-duty commercial fishing piers would be demolished and replaced, bulkhead asphalt repaired, and electrical supply upgraded (Block Island Times 2020). If the Port of Galilee is chosen to support Revolution Wind O&M activities, there would be no Project-related upgrades at the Port of Galilee. Port Jefferson has completed a master plan and an upper port revitalization plan, which is a blight study and urban renewal plan pursuant to New York State law. It involved rezoning certain areas and supporting major housing and mixed-use projects within the town (Village of Port Jefferson 2019). No specific non-Project improvements are proposed for Montauk Harbor, but NYSERDA issued an OSW master plan that notes Montauk Harbor as having the potential to be used or developed into facilities capable of supporting OSW projects (NYSERDA 2017).<br>Port activities could be delayed or area transportation routes could experience longer delays as a result of the overlap in construction activities. All activities would, however, be in accordance with land use goals and plans and would be subject to local land use and zoning regulations. Construction and operations improvements associated with the Project and other OSW energy development would occur within the boundaries of existing port facilities or repurposed industrial facilities, would be similar to existing activities at the existing ports, and would support state strategic plans and local land use goals for development of waterfront infrastructure as well as economic opportunities (see Section 3.11). State and local agencies would also be responsible for minimizing the impacts of these future development plans by ensuring continued access to ports and adjacent land | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | uses and minimizing or avoiding noise, air quality, and other impacts on nearby neighborhoods. Therefore, when considered in combination with past, present, and other reasonably foreseeable projects, the Proposed Action would have **negligible** adverse cumulative impacts on land use and coastal infrastructure. Alternatives C through F would slightly reduce impacts to port utilization, but impacts would remain the same as the Proposed Action: **negligible** adverse. | |
| | | | | **Onshore:** The Project is evaluating the use of the Port of Davisville at Quonset Point, Port of Galilee, Port Jefferson, and Port of Montauk to support O&M of the Project (see Table 3.3-24 in the COP). O&M buildings at or near some or all of these ports would be used for wind farm monitoring and equipment storage for multiple OSW projects—the RWF, SFWF, and Sunrise Wind Farm—and as such have utility that is independent of the Project. If the Port of Galilee or Port of Brooklyn are chosen as O&M facility locations, use of these ports would be limited to existing facilities maintained by these ports. Use of the other ports listed above would include using existing facilities as well as constructing additional facilities to support the RWF and other wind farms.<br>An existing upland building, called the Research Way O&M Building, is located approximately 6 miles from Port Jefferson at 22 Research Way in Setauket-East Setauket, New York. It is located within an office park that also hosts technology companies and health care providers among other businesses. The building was recently purchased by Northeast Offshore, LLC, and internal upgrades to establish office and warehouse space are planned. The planned work requires no governmental authorizations other than local building permits and would consist entirely of interior renovations to create workspaces. No external modifications or expansions are planned other than any necessary repairs to maintain the existing external appearance. | **Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. Construction and installation of Alternative G onshore components would be identical to the Proposed Action and would have **minor** beneficial impacts to land use and coastal infrastructure. There would be a long-term **minor** beneficial and a **negligible** adverse port utilization impact on land use and coastal infrastructure from O&M and decommissioning of onshore elements of Alternative G.<br>Development of an OSW industry on the Mid-Atlantic OCS could incentivize the expansion or improvement of regional ports to support planned and future projects. Therefore, cumulative impacts associated with the Project when combined with past, present, and reasonably foreseeable future activities would be **negligible** adverse on port utilization for Alternative G. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | The only other external planned work being discussed is maintenance of the parking lot, landscaping, and, potentially, signage. The Research Way facility would also be capable of serving multiple projects as well as general Orsted and Eversource business needs. A new building with up to 1,000 square feet of office space and up to 6,000 square feet of equipment storage would be constructed at the Port of Montauk. This facility could also serve as an O&M base for multiple OSW projects.<br>The ports under consideration for construction staging are industrial in character, designated by local zoning and land use plans for heavy industrial activity, and typically adjacent to other industrial or commercial land uses and major transportation corridors.<br>Activities associated with onshore construction of the Project would generate noise, vibration, and vehicular traffic and would temporarily alter views at one or more ports listed in Table 3.3.10-1 of the COP. Port improvements would result in combustion emissions from construction vehicles and equipment and could result in fugitive particulate emissions from soil movement. These impacts would be typical for construction in and operation of industrial ports. Noise, vibration, vehicular traffic increases, and vehicular emission generation would be short term. Potential landside transportation impacts would be minimized through construction hour restrictions, improvements such as road widening and signalization, and appropriate route selection (BOEM 2016). Activity and development from the Project would not occur at levels above those typically experienced or expected at these facilities, would not hinder other nearby land use or use of coastal infrastructure, and would comply with local land use and zoning regulations. Overall, construction and installation of onshore components would have **minor** beneficial impacts to land use and coastal infrastructure by supporting designated uses at ports and port improvements and/or | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | redevelopment. Improvements such as road widening and signalization would provide transportation flow benefits over the long term. the Proposed Action and Alternatives C through F include identical onshore facilities and activities and impacts.<br><br>Project O&M would involve routine daily activities at O&M facilities that are consistent with the zoned uses for those specific parcels. O&M facilities would include offices, warehouses, and associated accessory uses, which are consistent with the range of land uses associated with the ports listed in Table 3.3.10-1 of the COP. The increased activity within any of the listed port areas zoned for business and industrial uses would reinforce the designated land use and provide a source of investment in the coastal infrastructure. O&M activities would be limited to temporary, periodic use of vehicles and equipment; associated impacts would be consistent with zoned and designated uses for commercial and industrial port facilities. The presence of O&M facilities and related O&M activities would contribute to the economic vitality of ports. O&M of onshore components would therefore have minor beneficial impacts to land use and coastal infrastructure by supporting designated uses at ports and supporting port improvements and/or redevelopment that would benefit other projects and port uses beyond those necessary for the Project (see Section 3.11). Therefore, there would be a long-term **minor** beneficial and a **negligible** adverse port utilization impact on land use and coastal infrastructure from O&M and decommissioning of onshore elements of the Proposed Action and Alternatives C through F.<br><br>Development of an OSW industry on the Mid-Atlantic OCS could incentivize the expansion or improvement of regional ports to support planned and future projects. Potential future activities could include upgrades to port facilities that would have long-term beneficial impacts to other users over a long time period. All future port improvements would be subject to | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | independent environmental permitting and regulatory review and are not part of the Project. Therefore, cumulative impacts associated with the Project when combined with past, present, and reasonably foreseeable future activities would be **negligible** adverse on port utilization for the Proposed Action and Alternatives C through F. | |
| Presence of structures: Viewshed | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA, which are visible from some coastal locations in New York, Connecticut, Rhode Island, and Massachusetts. | Non-OSW structures that could be viewed in conjunction with the offshore components would be limited to met towers. Marine activity would also occur within the offshore viewshed. | Future OSW activities would add 3,088 additional structures within the GAA. Future OSW activities would also result in onshore placement of structures. Structures would be built in accordance with state and local land use, zoning, and building regulations and therefore would have minimal land use and coastal infrastructure impacts. While the presence of additional onshore structures could impact land uses by reducing the amount of land available for other uses and generating short-term construction impacts, all structures would be built in accordance with state and local zoning and building regulations and would therefore have a minimal impact on land use and coastal infrastructure. On this basis, the effects of the presence of structures on land use under the No Action Alternative would be long term **negligible** adverse. | **Offshore:** The installation and operation of up to 102 offshore structures for the Proposed Action and construction of the IAC, OSS-link cable, and RWEC would not result in any impacts to land use and coastal infrastructure because these impacts would occur offshore and would not overlap with onshore land uses. Therefore, there would be a **negligible** adverse impact from the presence of structures on land use and coastal infrastructure from O&M and decommissioning of offshore elements of the Proposed Action and Alternatives C through F.<br>Similarly, when considered in combination with past, present, and other reasonably foreseeable projects, the Proposed Action would have no effect on land use and coastal infrastructure; therefore, the cumulative impact would be **negligible** adverse. Alternatives C through F would result in incrementally smaller impacts, but not measurably reduce land use and coastal infrastructure impacts compared to the Proposed Action. | **Offshore:** The installation and operation of up to 67 offshore structures for Alternative G and construction of the IAC, OSS-link cable, and RWEC would not result in any impacts to land use and coastal infrastructure because these impacts would occur offshore and would not overlap with onshore land uses. Therefore, there would be a **negligible** adverse impact from the presence of structures on land use and coastal infrastructure from O&M and decommissioning of offshore elements of Alternative G.<br>Similarly, when considered in combination with past, present, and other reasonably foreseeable projects, Alternative G would have no effect on land use and coastal infrastructure; therefore, the cumulative impact would be **negligible** adverse. |
| | | | | **Onshore:** Onshore structures that would be constructed as part of the Project include the onshore transmission cable, ICF, and OnSS.<br>The OnSS would require temporary disturbance (construction footprint) of up to 7.1 acres to facilitate construction. This includes an operational footprint of 3.8 acres. The ICF would require a temporary construction footprint of approximately 4.0 acres, which includes the 1.6-acre operational footprint.<br>The ICF would be constructed adjacent to the existing Davisville Substation, in the zoned Quonset Business Park District. Installation of | Similar impacts to the Proposed Action and Alternatives C through F.<br>Therefore, the presence of structures would result in a **negligible** adverse impact on land use and coastal infrastructure. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | the ICF could increase visibility of the existing substation to nearby residences along Camp Avenue. However, construction would take place adjacent to the existing Davisville Substation, in lots surrounded by mature trees.<br>Construction activities associated with onshore facilities is expected to take approximately 1 year and includes clearing and grading, excavating, installing foundations, and constructing the facility. There are no nighttime visually sensitive areas (public parks, beaches, or other public recreational facilities) near the OnSS and ICF that would be impacted by nighttime construction lighting (see Section 3.20). The visual impacts of the ICF would be minimized through the installation of vegetation to provide year-round screening from nearby Camp Avenue, Circuit Drive, and Roger Williams Way; appropriate substation siting; low-profile design; and minimal lighting, all of which would be directed downward (VHB 2023c). As designed, the interconnection facility would generate sound below existing, ambient sound levels (VHB 2023b). According to federal, state, and local noise standards, there would be no impact as a result of the operation of the ICF. All Project-related construction would take place within areas zoned for industrial and commercial development and would be subject to land use and zoning regulations that limit impacts.<br>Therefore, the presence of structures would result in a **negligible** adverse impact on land use and coastal infrastructure from construction and installation of onshore elements of all Project alternatives.<br>O&M activities would include periodic inspections and repairs at the ICF and cable access manholes, which would require minimal use of worker vehicles and construction equipment. Periodic maintenance and repairs would have temporary impacts on access to adjacent land uses. All onshore structures that are part of the Proposed Action and Alternatives C through F and any necessary modifications to structures would be consistent with land | |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | use and zoning regulations. Therefore, the impact from the presence of structures on land use and coastal infrastructure would be **negligible** adverse.<br>Reasonably foreseeable future actions would have similar impacts to the Proposed Action and Alternatives C through F in terms of the presence of structures. Therefore, cumulative impacts associated with the Project when combined with past, present, and reasonably foreseeable future activities would be **negligible** adverse on land use and coastal infrastructure for all Project alternatives. | |

* Includes all constructed and permitted COP projects within the land use and coastal infrastructure GAA: Block Island, SFWF, Vineyard Wind 1, and Coastal Virginia Offshore Wind.

## Navigation and Vessel Traffic

No IPFs with solely negligible impacts were identified.

**Table E2-14**. **Summary of Activities and the Associated Impact-Producing Factors for Navigation and Vessel Traffic**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Anchoring | Constructed and permitted OSW COP projects are introducing an estimated 943 acres of anchoring in the GAA. Larger commercial vessels (specifically tankers) also sometimes anchor outside of major ports to transfer their cargo to smaller vessels for transport into port, an operation known as lightering. These anchors have deeper ground penetration and are under higher stresses. Smaller vessels (commercial fishing or recreational vessels) would anchor for fishing and other recreational activities. These activities cause temporary to short-term impacts on navigation in the immediate anchorage area. All vessels could anchor in an emergency scenario (such as power loss) if they lose power to prevent them from drifting and creating navigational hazards for other vessels or drifting into structures. | Lightering and anchoring operations are expected to continue at or near current levels, with the expectation of a moderate increase commensurate with any increase in tankers visiting ports. Deep draft vessel visits to major port visits are expected to increase as well, increasing the potential for an emergency need to anchor and creating navigational hazards for other vessels. Recreational activity and commercial fishing activity would likely stay largely the same related to this IPF. | See Section 3.16.2.2.2 for analysis. | See Sections 3.16.2.3 and 3.16.2.4 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. | See Sections 3.16.2.5 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. |
| Port utilization: Expansion | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing | Ports would need to perform maintenance and upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host | See Section 3.16.2.2.2 for analysis. | See Sections 3.16.2.3 and 3.16.2.4 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. | See Sections 3.16.2.5 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance. Impacts from these activities would be short term and could include congestion in ports, delays, and changes in port usage by some fishing or recreational vessel operators. | larger deep draft vessels as they continue to increase in size. Impacts would be short term and could include congestion in ports, delays, and changes in port usage by some fishing or recreational vessel operators. | | | |
| Presence of structures: Allisions | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA. An allision occurs when a moving vessel strikes a stationary object. The stationary object can be a buoy, a port feature, or another anchored vessel. There are two types of allisions that occur: drift and powered. A drift allision generally occurs when a vessel is powered down due to operator choice or power failure. A powered allision generally occurs when an operator fails to adequately control their vessel movements or is distracted. The presence of OSW structures increases the GAA's navigational complexity, thereby increasing the risk of allision or collision. However, WTG spacing is anticipated to reduce, but not eliminate, navigational complexity. | Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not anticipate vessel traffic to greatly increase over the next 35 years. Vessel allisions with non-OSW stationary objects should not increase meaningfully without a substantial increase in vessel congestion. | See Section 3.16.2.2.2 for analysis. | See Sections 3.16.2.3 and 3.16.2.4 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. | See Sections 3.16.2.5 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. |
| Presence of structures: Fish aggregation | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA. Items in the water, such as ghost fishing gear, buoys, and energy platform foundations can create an artificial reef effect, aggregating fish. Recreational and commercial fishing can occur near the artificial reefs. Recreational fishing is more popular than commercial fishing near artificial reefs because commercial mobile fishing gear can risk snagging on the artificial reef structure. | Fishing near artificial reefs is not expected to change meaningfully over the next 35 years. | See Section 3.16.2.2.2 for analysis. | See Sections 3.16.2.3 and 3.16.2.4 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. | See Sections 3.16.2.5 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. |
| Presence of structures: Navigation hazard | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA. Vessels need to navigate around structures to avoid allisions. When multiple vessels need to navigate around a structure, then navigation is made more complex as the vessels need to avoid both the structure and each other. The presence of OSW structures increases the GAA's navigational complexity, thereby increasing the risk of allision or collision. However, WTG spacing is | Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not anticipate vessel traffic to greatly increase over the next 35 years. Even with increased port visits by deep draft vessels, this is still a relatively small adjustment when considering the whole of New England vessel traffic. The presence of navigation hazards is expected to continue at or near current levels. | See Section 3.16.2.2.2 for analysis. | See Sections 3.16.2.3 and 3.16.2.4 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. | See Sections 3.16.2.5 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | anticipated to reduce, but not eliminate, navigational complexity during the operations phases of the projects. | | | | |
| Presence of structures: Space use conflicts | Currently, the offshore area is occupied by marine trade, stationary and mobile fishing, and survey activities. Constructed and permitted OSW COP projects are also introducing 81 structures into the GAA. The presence of OSW structures increases the GAA's navigational complexity. The attraction of artificial reef effects also increases vessel congestion and the risk of allision, collision, and spills near structures. However, WTG spacing is anticipated to reduce, but not eliminate, space-use conflicts during the operations phases of the projects. | Reasonably foreseeable activities (non–OSW) would not result in additional offshore structures. | See Section 3.16.2.2.2 for analysis. | See Sections 3.16.2.3 and 3.16.2.4 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. | See Sections 3.16.2.5 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. |
| New cable emplacement/ maintenance | Constructed and permitted OSW COP projects are introducing an estimated 462 miles of new offshore cable in the GAA. Within the GAA for navigation and vessel traffic, existing cables could also require access for maintenance activities. These cable activities could cause temporary increases in vessel traffic and navigational complexity. | The FCC has two pending submarine telecommunication cable applications in the North Atlantic. Future new cables would cause temporary increases in vessel traffic during installation or maintenance, resulting in infrequent, localized, short-term impacts over the next 35 years. Care would need to be taken by vessels that are crossing the cable routes during these activities. | See Section 3.16.2.2.2 for analysis. | See Sections 3.16.2.3 and 3.16.2.4 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. | See Sections 3.16.2.5 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. |
| Traffic: Aircraft, vessels, collisions | See Table E2-15 (Summary of Activities and the Associated Impact-Producing Factors for Other Marine Uses: Military and National Security Uses) for a discussion of search and rescue (SAR) aircraft and vessels with respect to traffic. SAR helicopters are the main aircraft that could be flying at low enough heights to risk interaction with WTGs. USCG SAR aircraft need to fly low enough that they can spot objects in the water.<br>See also the sub-IPF for Presence of structures: Navigation hazard | SAR operations could be expected to increase with any increase in vessel traffic. As noted in Table E2-15, no future non-OSW stationary structures were identified within the offshore GAA. Therefore, because vessel traffic volume associated with future non-OSW is not expected to increase appreciably, neither should SAR operations.<br>See also the sub-IPF for Presence of structures: Navigation hazard | See Section 3.16.2.2.2 for analysis. | See Sections 3.16.2.3 and 3.16.2.4 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. | See Sections 3.16.2.5 and Section 3.16.2.1, Table 3.16-3 for analysis of impacts. |

*Includes three constructed and permitted COP projects within the navigation and vessel traffic GAA: Block Island, SFWF, Vineyard Wind 1.

## Other Marine Uses: Military and National Security

**Table E2-15. Summary of Activities and the Associated Impact-Producing Factors for Other Marine Uses: Military and National Security Uses**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases and discharges | Accidental releases and discharges of fuels and fluids have the potential to occur during vessel usage for permitted and built OSW COP projects, dredge material ocean disposal, fisheries use, marine transportation, military use, survey activities, and submarine cable line and pipeline laying activities. | Future accidental releases from offshore vessel usage, spills, and consumption would likely continue on a similar trend to ongoing activities. Impacts are unlikely to affect military and national security uses. | Fuels and oils would be required for construction, installation, O&M, and decommissioning of future OSW activities. In the event of a spill or release during construction and installation activities, offshore water quality would be degraded. OSRPs would be required for all future OSW projects, which includes processes for rapid spill response, containment, cleanup, and other measures that would help minimize impacts on water quality from spills. Releases during construction of future OSW activities during all phases of project construction would generally be localized and short term, resulting in little change to water quality. Therefore, this IPF would have a **negligible** adverse impact on military and national security uses because there would be no effect on this resource. | **Offshore:** Fuels and oils would be required for offshore construction and installation equipment, vessels, and infrastructure over the 18-month construction period. In the event of a spill or release during construction and installation activities, offshore water quality would be degraded. As described in Section 3.21.1.2, the likelihood of a spill due to construction and installation activities and weather events is low (once per 1,000 years). An OSRP has been prepared for the Project and includes processes for rapid spill response, containment, cleanup, and other measures that would help minimize impacts on water quality from spills. Therefore, this IPF would have a **negligible** adverse impact on military and national security uses. Alternatives C through F would reduce the number of WTGs and their associated IACs, which would have an associated reduction in associated vessel and equipment use. This decrease in WTGs would result in a reduction of possible accidental releases and discharges, but the level of impact would not measurably change relative to the Proposed Action. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, this IPF would have a negligible adverse impact on military and national security uses. Alternative G would result in fewer WTGs, which would result in a reduced number of vessels and associated equipment used in construction and operations, resulting in a reduction of possible accidental releases and discharges, but would not measurably change in relation to the Proposed Action. |
| Anchoring | Impacts from anchoring have the potential to occur due to permitted and built OSW COP projects, ongoing military use and survey, and commercial and recreational activities. The presence of anchored construction vessels could cause military vessels to change course or otherwise alter operations and could increase demand for SAR. | Impacts from anchoring could occur on a semiregular basis over the next 35 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. | See Section 3.17.2.4.2 for analysis. | See Section 3.17.2.9 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| New cable emplacement/maintenance | Constructed and permitted OSW COP projects are introducing an estimated 163 miles of new offshore cable in the GAA. This and other ongoing cable maintenance activities can cause military vessels to change course or otherwise alter operations and could increase demand for SAR; these | Cable maintenance or replacement of existing cables in the GAA would occur infrequently, and would generate short-term disturbances. | See Section 3.17.2.4.2 for analysis. | See Section 3.17.2.9 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | disturbances would be local and limited to emplacement corridors. | | | | |
| Light | Constructed and permitted OSW COP projects are introducing 13 lighted structures into the GAA, as well as lighted vessels. Impacts from lighting on military and national security also include light associated with military, commercial, or construction vessel traffic. Ocean vessels have an array of lights, including navigational lights and deck lights. Offshore buoys and towers emit low-intensity light. Onshore structures, including houses and ports, emit substantially more light on an ongoing basis. Impacts are expected to be minimal. | Future activities with the potential to result in lighting impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Light pollution from vessel traffic would continue at the current intensity along the Northeast coast, with a slight increase due to population growth and development over time. Light from onshore structures is expected to gradually increase in line with human population growth along the coast, with minimal offshore impacts. | See Section 3.17.2.4.2 for analysis. | See Section 3.17.2.9 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Noise | Noise impacts are expected from OSW and non-OSW construction and vessel traffic. Construction occurs frequently in nearshores of populated areas in New England and the Mid-Atlantic but infrequently offshore. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this IPF consist of constructed and permitted OSW COP projects, commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels. | Noise from construction near shorelines is expected to gradually increase in line with human population growth along the coast of the GAA for this resource. Planned new barge routes and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain. | While future OSW activities without the Proposed Action would result in construction and decommissioning noise and limited operational noise, noise is not expected to impact military and national security as all noise would be lower than regulatory thresholds and would occur in geographic areas in which the military does not typically operate. Therefore, the effects of noise on military and national security under the No Action Alternative would be **negligible** adverse. | **Offshore:** While construction and installation, O&M and decommissioning of offshore elements of the Proposed Action would result in construction noise, noise is not expected to impact military and national security as all noise would be lower than regulatory thresholds. Alternatives C through F would reduce the number of WTGs and their associated IACs, which would have an associated reduction in noise associated with vessel and equipment use, but otherwise, the level of impact would not measurably change relative to the Proposed Action. Therefore, the effects of noise on military and national security under the Proposed Action and Alternatives C through F would be **negligible** adverse.<br>The Project combined with reasonably foreseeable future actions would result in an increase in construction and decommissioning noise in the RI/MA WEA. However, noise impacts would be distributed across a large geographic area and would not likely occur at the same time. Noise is not anticipated to impact military or national security. Therefore, because Project activities combined with reasonably foreseeable activities would result in a minimal increase in noise offshore that is not expected to impact military and national security uses, | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, the effects of noise on military and national security under Alternative G would be **negligible** adverse.<br>The Project combined with reasonably foreseeable future actions would result in an increase in construction and decommissioning noise in the RI/MA WEA. However, noise impacts would be distributed across a large geographic area and would not likely occur at the same time. Noise is not anticipated to impact military or national security. Therefore, because Project activities combined with reasonably foreseeable activities would result in a minimal increase in noise offshore that is not expected to impact military and national security uses, the cumulative impacts would be **negligible** adverse. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | the cumulative impacts would be **negligible** adverse. | |
| Port utilization | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance. Impacts from these activities would be short term and could include congestion in ports, delays, and changes in navigation patterns at nearby airports. The increased activity could cause potential conflicts with military aircraft and vessels. | Ports would need to perform maintenance and upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host larger deep draft vessels as they continue to increase in size. Impacts would be short term and could include congestion in ports, delays, changes in port usage by some fishing or recreational vessel operators, and changes in navigation patterns. | There could be a very minimal increase in vessel use at ports associated with the No Action Alternative. The number of construction vessels would increase due to future OSW activities without the Proposed Action, which could result in delays and congestion at ports that could lead to potential conflicts with military aircraft and vessels due to increased activity in the vicinity of the airports listed in the Affected Environment. Port improvements and construction activities in or near ports could require alteration of navigation patterns at nearby airports, which could impact military uses. Navigational hazards and collision risks at ports and in transit routes would be reduced as construction is completed, and all navigation hazards and collision risks would be gradually eliminated during decommissioning as offshore WTGs are removed. However, vessel traffic would also be spread among multiple ports to ensure sufficient capacity exists at each port and in each waterway. Therefore, port utilization is expected to have a **negligible** adverse effect on military and national security. | **Offshore:** the Proposed Action and Alternatives C through F would require construction and O&M vessels, which could result in minor delays and congestion at ports. This could lead to potential conflicts with military aircraft and vessels due to increased port activity. Although no port improvements are currently planned as part of the Proposed Action and Alternatives C through F, if port upgrades are required, port improvements and construction activities in or near ports could require alteration of navigation patterns at nearby airports, which could impact military uses. Navigational hazards and collision risks at ports and in transit routes would be reduced as construction and O&M is completed. Vessel traffic would also be spread among multiple ports to ensure sufficient capacity exists at each port and in each waterway. However, port utilization is not expected to increase beyond what is currently allowed under land use regulations. Therefore, port utilization is expected to have a **negligible** adverse effect on military and national security.<br>Although Alternatives C through F would result in a slight reduction of port utilization due to a reduction of the number of WTGs and their associated IACs, impacts on this resource would be similar to the Proposed Action.<br>Project activities combined with reasonably foreseeable activities would result in a minimal increase in port utilization that would be accounted for through port improvements and capacity planning. Therefore, the cumulative impacts of noise on military and national security would be **negligible** adverse. | **Offshore:** Although Alternative G would result in a slight reduction of port utilization due to a reduction of the number of WTGs and their associated IACs, impacts on this resource would be similar to the Proposed Action.<br>Project activities combined with reasonably foreseeable activities would result in a minimal increase in port utilization that would be accounted for through port improvements and capacity planning. Therefore, the cumulative impacts of noise on military and national security would be **negligible** adverse. |
| Presence of structures: Allisions | Constructed and permitted OSW COP projects are introducing 13 structures into the GAA. Other existing stationary facilities that present allision risks include dock facilities, meteorological buoys associated with OSW lease areas, and other offshore or shoreline-based structures. OSW project use | No additional non-OSW stationary structures were identified within the GAA. Stationary structures such as private or commercial docks could be added close to the shoreline. | See Section 3.17.2.4.2 for analysis. | See Section 3.17.2.9 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | of navigation safety zones and WTG spacing is anticipated to reduce some of the risk of collisions and allisions. | | | | |
| Presence of structures: Fish aggregation | Constructed and permitted OSW COP projects are introducing 13 structures into the GAA. These stationary structures act as fish aggregating devices (FADs). These FADs can concentrate recreational and commercial fishing, which can add to conflict or collision risks for military and national security vessels and increase demand for SAR operations. | No future non-OSW additional stationary structures that would act as FADs were identified within the GAA. | See Section 3.17.2.4.2 for analysis. | See Section 3.17.2.9 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Presence of structures: Navigation hazard | Constructed and permitted OSW COP projects are introducing 13 structures into the GAA. Other existing stationary facilities within the GAA that present navigational hazards consist of communication towers; dock facilities; and other onshore and offshore commercial, industrial, and residential structures. OSW project use of navigation safety zones and WTG spacing is anticipated to reduce some of these risks to navigation. | No future non-OSW stationary structures were identified within the offshore GAA. Onshore, development activities are anticipated to continue, with additional proposed communications towers and onshore commercial, industrial, and residential developments. | See Section 3.17.2.4.2 for analysis. | See Section 3.17.2.9 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Presence of structures: Space use conflicts | Constructed and permitted OSW COP projects are introducing 13 structures into the GAA. Other existing stationary facilities within the GAA that present a navigational hazard include communication towers; dock facilities; and other onshore and offshore commercial, industrial, and residential structures. OSW project use of navigation safety zones and WTG spacing is anticipated to reduce some of these risks to navigation. | No future non-OSW stationary structures were identified within the offshore GAA. Onshore, development activities are anticipated to continue, with additional proposed communications towers and onshore commercial, industrial, and residential developments. | See Section 3.17.2.4.2 for analysis. | See Section 3.17.2.9 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Presence of structures: Transmission cable infrastructure | Seven submarine cable corridors cross cumulative lease areas. Constructed and permitted OSW COP projects are also introducing an estimated 163 miles of new offshore cable in the GAA. Cable activities could cause military vessels to change course or otherwise alter operations and could increase demand for SAR. These impacts are expected to be limited to cable emplacement corridors. | Submarine cables would remain in current locations with infrequent maintenance continuing along those cable routes for the foreseeable future. | See Section 3.17.2.4.2 for analysis. | See Section 3.17.2.9 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Traffic: Vessels, collisions | Current vessel traffic in the region is described in Section 3.16.1. Vessel activities associated with OSW in the cumulative lease areas is currently limited to site assessment | Continued vessel traffic in the region is described in Section 3.16.1. | See Section 3.17.2.4.2 for analysis. | See Section 3.17.2.9 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | surveys and constructed and permitted OSW COP projects. | | | | |
| Traffic: Aviation | Onshore and offshore military and national security use areas could have designated surface and subsurface boundaries and special use airspace. Military air traffic use the area, and government and other private aircraft could occasionally fly over the WEA for data collection and SAR operations. Aircraft are also used for scientific and academic surveys in marine environments.<br>Warning Area W-105A is a special use airspace area primarily used by the U.S. Air Force located offshore Massachusetts and Rhode Island, and overlapping the RI and MA lease areas. | Although no future non-OSW stationary structures were identified within the offshore GAA, aircraft would continue to be used to conduct scientific research studies as well as wildlife monitoring and preconstruction surveys. SAR operations could be expected to increase with any increase in vessel traffic. However, because vessel traffic volume associated with future non-OSW is not expected to increase appreciably, neither should SAR operations. Commercial air traffic could also be expected to increase with current trends. | See Section 3.17.2.4.2 for analysis. | See Section 3.17.2.9 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Climate Change | Climate change has resulted in a measurable increase in annual precipitation on the East Coast, which could impact military and national security-related aviation and air traffic due to more inclement weather incidents. | Sea level rise and storm severity/frequency would increase due to the effects of climate change. | Climate change has resulted in a measurable increase in annual precipitation on the East Coast, which could impact military and national security–related aviation and air traffic due to more inclement weather incidents. Future OSW activities could result in construction activities that increase GHG emissions. Increased GHG emissions could contribute to climate change impacts during construction. However, the construction of future OSW facilities could ultimately help slow the negative effects of climate change by redistributing some of the East Coast's energy generation to renewable sources, resulting in a net decrease in GHG emissions from energy generation. On this basis, the effects of climate change on military and national security under the No Action Alternative would be **negligible** adverse. | Similar to the No Action Alternative, the construction and installation, O&M, and decommissioning of the Proposed Action and Alternatives C through F could contribute to climate change impacts during construction. However, the Project could also ultimately help slow the negative effects of climate change by redistributing some of the East Coast's energy generation to renewable sources, resulting in a net decrease in GHG emissions from energy generation. On this basis, the effects of climate change on military and national security under the Proposed Action and Alternatives C through F would be **negligible** adverse. | Similar impacts to the Proposed Action and Alternatives C through F. On this basis, the effects of climate change on military and national security under Alternative G would be **negligible** adverse. |

* Includes one constructed and permitted COP project that occurs within the military and national security GAA: SFWF.

## Other Marine Uses: Aviation and Air Traffic

**Table E2-16. Summary of Activities and the Associated Impact-Producing Factors for Other Marine Uses: Aviation and Air Traffic**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases and discharges | Accidental releases and discharges have the potential to occur during vessel usage for permitted and built OSW COP projects, | No future activities were identified within the GAA other than ongoing activities. | Accidental releases and discharges would not overlap with aviation and air traffic uses and | **Offshore:** The effects of this IPF from the Proposed Action and Alternatives C through F would not impact aviation and air traffic | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact |

These activities do not overlap with aviation and air traffic uses and areas. | | areas and therefore would result in a **negligible** adverse impact. | because accidental releases and discharges would not overlap with aviation and air traffic uses. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource. | because there would be no effect on this resource. |
| | | | | **Onshore:** Same as offshore impacts. | **Onshore:** Same as offshore impacts. |
| Anchoring and new cable emplacement/maintenance | Anchoring activities have the potential to occur due to permitted and built OSW COP projects, ongoing military use and survey, and commercial and recreational activities. These activities do not overlap with aviation and air traffic uses and areas. | No future activities were identified within the GAA other than ongoing activities. | Future OSW activities would require adding new cables and maintaining them as part of future wind projects. The offshore effects of anchoring and new cable emplacement/maintenance would have no bearing on aviation or air traffic, as these uses do not overlap. Onshore construction and maintenance of cables associated with future OSW activities would occur in areas that are not likely to overlap with aviation uses. The use of onshore construction equipment would not interfere with air traffic. On this basis, the effects of anchoring and new cable emplacement/maintenance on aviation and air traffic under the No Action Alternative would be **negligible** adverse. | **Offshore:** Onshore construction, maintenance, and decommissioning of cables associated with future OSW activities would occur in areas that are not likely to overlap with aviation uses. The use of onshore construction equipment would not interfere with air traffic. On this basis, the effects of anchoring and new cable emplacement/maintenance on aviation and air traffic under the Proposed Action and Alternatives C through F would be **negligible** adverse. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. On this basis, the effects of anchoring and new cable emplacement/maintenance on aviation and air traffic under Alternative G would be **negligible** adverse. |
| | | | | **Onshore:** Same as offshore impacts. | **Onshore:** Same as offshore impacts. |
| Light | Constructed and permitted OSW COP projects are introducing 81 lighted structures into the GAA, as well as lighted vessels. Other impacts from lighting on aviation and air traffic include light associated with non-OSW military, commercial, or construction vessel traffic. Ocean vessels have an array of lights, including navigational lights and deck lights. Offshore buoys and towers emit low-intensity light. Onshore structures, including houses and ports, emit substantially more light on an ongoing basis. Impacts are expected to be minimal. | Future activities with the potential to result in lighting impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Light pollution from vessel traffic would continue at the current intensity along the Northeast coast, with a slight increase due to population increase and development over time. Light from onshore structures is expected to gradually increase in line with human population growth along the coast, with minimal offshore impacts. | See Section 3.17.2.2.2 for analysis. | See Section 3.17.2.7 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Noise | Noise impacts are expected from OSW and non-OSW construction and vessel traffic. Construction occurs frequently in nearshores of populated areas in New England and the Mid-Atlantic but infrequently offshore. Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this IPF consist of | Noise from construction near shorelines is expected to gradually increase in line with human population growth along the coast of the GAA for this resource. Planned new barge routes and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain. | While future OSW activities without the Proposed Action would result in construction and decommissioning noise and limited operational noise, noise is not expected to impact aviation and air traffic. Therefore, the effects of noise on aviation and air traffic under the No Action Alternative would be **negligible** adverse. | **Offshore:** All Project-associated noise would comply with regulatory noise thresholds and noise is not expected to impact aviation and air traffic. Alternatives C through F could result in a slight reduction to construction and operational noise but otherwise would be similar to the Proposed Action. Therefore, the effects of noise on aviation and air traffic | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, the effects of noise on aviation and air traffic under Alternative G would be **negligible** adverse.<br>Reasonably foreseeable future actions would occur over a dispersed geographic area and would not generate noise high enough to |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | constructed and permitted OSW COP projects, commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Noise is not expected to impact aviation and air traffic. | | | under the Proposed Action and Alternatives C through F would be **negligible** adverse.<br>Reasonably foreseeable future actions would occur over a dispersed geographic area and would not generate noise high enough to impact aviation uses. Therefore, the cumulative impacts would also be **negligible** adverse. | impact aviation uses. Therefore, the cumulative impacts would also be **negligible** adverse. |
| | | | | **Onshore:** There would be onshore noise impacts associated with the construction of Alternatives B through F. Construction would be limited to daylight hours, and noise impacts would consist of noise generated from heavy equipment performing clearing, grading, excavating, installing foundations, and heavy lifting of substation components. Noise modeling shows that noise is expected to remain below Town of North Kingstown noise ordinance levels. Because there is no permanent noise-generating equipment associated with the onshore transmission cable, operational noise of the underground cables is expected to have no impacts to aviation and air traffic. The OnSS and ICF, as designed, would generate sound similar to or below existing ambient sound levels; therefore, operational noise levels would not have an impact on aviation and air traffic. It is expected that reasonably foreseeable future actions would have similar noise impacts to the Proposed Action and Alternatives C through F. Therefore, impacts associated with the Project when combined with past, present, and reasonably foreseeable future activities would be **negligible** adverse on aviation and air traffic. | **Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, impacts associated with the Project when combined with past, present, and reasonably foreseeable future activities would be **negligible** adverse on aviation and air traffic. |
| Port utilization | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance. Impacts from these activities would be short term and could include congestion in ports, delays, and changes in navigation patterns at nearby airports. The increased activity could | Ports would need to perform maintenance and upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host larger deep draft vessels as they continue to increase in size. Impacts would be short term and could include congestion in ports, delays, and changes in navigation patterns at nearby airports. | See Section 3.17.2.2.2 for analysis. | See Section 3.17.2.7 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | cause potential impacts to aviation and air traffic. | | | | |
| Presence of structures: Navigation hazard | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA. Other existing aboveground stationary facilities within the GAA that present navigational hazards include communication towers, dock facilities, and other onshore and offshore structures exceeding 200 feet in height. The addition of these structures increases navigational complexity and may change aircraft navigation patterns for aircraft flying at low altitudes and for airports in the vicinity, increasing collision risks for some aircraft. However, more than 90% of existing air traffic in the GAA would occur at altitudes that would not be impacted by the presence of WTGs. | No future non-OSW stationary structures were identified within the offshore GAA. Onshore development activities are anticipated to continue with additional proposed communications towers. | See Section 3.17.2.2.2 for analysis. | See Section 3.17.2.7 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Presence of structures: Space use conflicts | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA. Other existing aboveground stationary facilities within the GAA that could cause space use conflicts for aircraft consist of communication towers, and other onshore and offshore structures exceeding 200 feet in height. Impacts would be as described for Presence of structures: Navigation hazard. | No future non-OSW stationary structures were identified within the offshore GAA. Onshore, development activities are anticipated to continue with additional proposed communications towers. | See Section 3.17.2.2.2 for analysis. | See Section 3.17.2.7 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Traffic: Aviation | Onshore and offshore military and national security use areas could have designated surface and subsurface boundaries and special use airspace. Military air traffic use the area, and government and other private aircraft could occasionally fly over the WEA for data collection and SAR operations. Aircraft are also used for scientific and academic surveys in marine environments.<br>Warning Area W-105A is a special use airspace area primarily used by the U.S. Air Force located offshore Massachusetts and Rhode Island, and overlapping the RI and MA lease areas. | Although no future non-OSW stationary structures were identified within the offshore GAA, aircraft would continue to be used to conduct scientific research studies as well as wildlife monitoring and preconstruction surveys. SAR operations could be expected to increase with any increase in vessel traffic. However, because vessel traffic volume associated with future non-OSW is not expected to increase appreciably, neither should SAR operations. Commercial air traffic could also be expected to increase with current trends. | See Section 3.17.2.2.2 for analysis for offshore impacts. This IPF would not impact onshore uses. | See Section 3.17.2.7 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts for offshore impacts. This IPF would not impact onshore uses. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Traffic: Vessels | Current vessel traffic in the region is described in Section 3.16.1. The GAA would continue to have numerous ports, and the extensive marine traffic related to constructed and permitted OSW COP | Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not anticipate vessel traffic to greatly increase over the next 30 years. Even with increased | See Section 3.17.2.2.2 for analysis. | See Section 3.17.2.7 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | projects, shipping, fishing, and recreation would continue to be important to the region's economy. | port visits by deep draft vessels and consistent generation of new vessel traffic by proposed barge routes and dredging demolition sites, this is still a relatively small adjustment when considering the whole of New England vessel traffic. | | | |
| Climate change | Climate change has resulted in a measurable increase in annual precipitation on the East Coast, which could impact military and national security–related aviation and air traffic due to more inclement weather incidents. | Sea level rise and storm severity/frequency would increase due to the effects of climate change. | Future OSW activities could result in construction activities that increase GHG emissions. Increased GHG emissions could contribute to climate change impacts. Climate change has resulted in a measurable increase in annual precipitation on the East Coast, which could impact aviation and air traffic due to more inclement weather incidents. However, the construction of future OSW facilities would ultimately help slow the negative effects of climate change by redistributing some of the East Coast's energy generation to renewable sources. On this basis, the effects of climate change on aviation and air traffic under the No Action Alternative would be **negligible** adverse. | **Offshore:** the Proposed Action and Alternatives C through F could result in GHG emissions during Project construction, O&M, and decommissioning phases as well as offset negative effects of climate change by redistributing some of the East Coast's energy generation to renewable sources. Therefore, the effects of climate change on aviation and air traffic under Alternatives C through F would be **negligible** adverse.<br>**Onshore:** Same as offshore impacts. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, the effects of climate change on aviation and air traffic under Alternative G would be **negligible** adverse. |

* Includes three constructed and permitted COP projects within the aviation and air traffic GAA: Block Island, SFWF, and Vineyard Wind 1.

## Other Marine Uses: Undersea Cables

**Table E2-17. Summary of Activities and the Associated Impact-Producing Factors for Other Marine Uses: Undersea Cables**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases and discharges | Accidental releases and discharges of fuels and fluids have the potential to occur during vessel usage for permitted and built OSW COP projects, dredge material ocean disposal, fisheries use, marine transportation, military use, survey activities, and submarine cable line and pipeline laying activities. | Future accidental releases from offshore vessel usage, spills, and consumption would likely continue on a similar trend to ongoing activities. | The effects of this IPF from the No Action Alternative would not impact undersea cables because accidental releases and discharges would result in water quality impacts that do not impact undersea cables. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource. | **Offshore:** The effects of this IPF from the Proposed Action and Alternatives C through F would not impact undersea cables because accidental releases and discharges would result in water quality impacts that do not impact undersea cables. Alternatives C through F would require fewer construction, O&M, and decommissioning vessel trips, reducing the risk of accidental releases and discharges, but there would be no measurable change on effects between all Project alternatives. Therefore, this IPF would result in a **negligible** adverse impact and **negligible** adverse cumulative impact under the Proposed Action and Alternatives C through F because there would be no effect on this resource. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Therefore, this IPF would result in a **negligible** adverse impact and **negligible** adverse cumulative impact under Alternative G because there would be no effect on this resource. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | **Onshore:** Same as offshore impacts. | **Onshore:** Same as offshore impacts. |
| Anchoring and new cable emplacement/maintenance | Impacts from this IPF have the potential to occur due to permitted and built OSW COP projects, ongoing military use and survey, commercial, and recreational activities. These disturbances would be limited to local areas. Any cable crossings are anticipated to include mapping and installation of cable protection at the crossing location, as well as standard design techniques for undersea cable installation. | Impacts from anchoring could occur on a semiregular basis over the next 35 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. Cable emplacement/maintenance would be infrequent and short term. | The presence of future OSW energy cables could preclude future submarine cable placement within any given development footprint, requiring future cables to route around these areas. However, the placement and presence of these cables would not prohibit the placement of additional cables and pipelines. Following standard industry procedures, cables and pipelines can be crossed without adverse impacts. The risk of allision to cable maintenance vessels could increase as more OSW energy projects are constructed. However, given the infrequency of required maintenance at any given location along a cable route, this risk is expected to be low. Impacts on submarine cables would be eliminated during decommissioning of OSW farms if export cables associated with those projects are removed. Therefore, the effects of anchoring and new cable emplacement/maintenance on undersea cables under the No Action Alternative would be **negligible** adverse. | **Offshore:** The installation of the RWEC would cross submarine cables that run through the regional waters. Most submarine cables pass through Green Hill, Rhode Island. In addition, there are NOAA nautical chart cable and pipeline areas that denote where such infrastructure could be located. Because Revolution Wind would use standard techniques during installation, O&M, and decommissioning to prevent damage to cables, adverse impacts would be **negligible** adverse. The effects of this IPF would be the same or slightly reduced from the Proposed Action under Alternatives C through F.<br>Up to 13,469 miles of cables are expected to be installed between 2021 and 2030 in the RI/MA WEA as part of reasonably foreseeable future actions. However, the placement and presence of these cables would not prohibit the placement of additional cables and pipelines. Impacts on undersea cables would be eliminated during decommissioning of OSW farms if export cables associated with those projects are removed. Therefore, Project activities combined with reasonably foreseeable activities would result in a **negligible** adverse impact on undersea cables. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F: impacts would be **negligible** adverse. The effects of this IPF would be the same or slightly reduced from the Proposed Action under Alternative G.<br>Impacts on undersea cables would be eliminated during decommissioning of OSW farms if export cables associated with those projects are removed. Therefore, Project activities combined with reasonably foreseeable activities would result in a **negligible** adverse impact on undersea cables. |
| | | | | **Onshore:** Same as offshore impacts. | **Onshore:** Same as offshore impacts. |
| Light | Constructed and permitted OSW COP projects are introducing 13 lighted structures into the GAA, as well as lighted vessels. Impacts from lighting also include light associated with military, commercial, or construction vessel traffic. Ocean vessels have an array of lights, including navigational lights and deck lights. Offshore buoys and towers emit low-intensity light. Impacts are expected to be minimal. | Future activities with the potential to result in lighting impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Light pollution from vessel traffic would continue at the current intensity along the Northeast coast, with a slight increase due to population increase and development over time. | Future OSW activities without the Proposed Action would result in an increase in permanent aviation warning lighting on WTGs offshore. All existing stationary structures would have navigation marking and lighting in accordance with FAA, USCG, and BOEM guidance to minimize allision risks. Implementation of navigational lighting and marking per FAA and BOEM requirements and guidelines would further reduce the risk of vessel collisions during installation or maintenance of undersea cables. This would result in a general increase of lights in the GAA, which could have a small negative impact on vessels performing cable construction or maintenance by increasing | **Offshore:** Lighting for construction, operations, and decommissioning under all Project alternatives would not impact undersea cables because light has no impact on undersea cables. Alternatives C through F would result in smaller Project footprints and fewer lighted offshore structures than the Proposed Action, but the reduction of impacts would not be measurable. This IPF would result in **negligible** adverse impacts because there would be no effect on this resource. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in **negligible** adverse impacts because there would be no effect on this resource. |
| | | | | **Onshore:** Same as offshore impacts. | **Onshore:** Same as offshore impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | navigational complexity. However, given that no new cables associated with non–wind energy actions are anticipated, the effects of light on undersea cable construction or maintenance under the No Action Alternative would be **negligible** adverse. | | |
| Noise | Ongoing noise from OSW and non-OSW construction occurs frequently nearshores of populated areas in New England and the Mid-Atlantic but infrequently offshore. Noise from construction near shorelines is expected to gradually increase over the next 30 years in line with human population growth along the coast of the GAA. | No future activities were identified within the GAA other than ongoing activities. | The effects of this IPF from the No Action Alternative would not impact undersea cables because noise has no impact on existing undersea cables or the construction or maintenance of undersea cables. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource. | **Offshore:** Project construction, operations, and decommissioning noise would not impact undersea cables because noise has no impact on undersea cables. Alternatives C through F would result in smaller Project footprints and fewer offshore structures than the Proposed Action, but the reduction of impacts would not be measurable. This IPF would result in **negligible** adverse impacts because there would be no effect on this resource.<br>**Onshore:** Same as offshore impacts. | **Offshore:** Project construction, operations, and decommissioning noise would not impact undersea cables because noise has no impact on undersea cables. Alternative G would result in smaller Project footprints and fewer offshore structures than the Proposed Action, but the reduction of impacts would not be measurable. This IPF would result in **negligible** adverse impacts because there would be no effect on this resource.<br>**Onshore:** Same as offshore impacts. |
| Port utilization | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance. Impacts from these activities would be short term and could include congestion in ports, delays, and changes in port usage. The increased activity could cause potential navigational complexity. | Ports would need to perform maintenance and upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host larger deep draft vessels as they continue to increase in size. Impacts would be short term and could include congestion in ports, delays, and changes in port usage by some fishing or recreational vessel operators. | There could be a very minimal increase in vessel use at ports associated with the No Action Alternative. Vessels used for undersea cable installation and maintenance of existing or future non–wind energy cables could conflict with vessels used for construction, O&M and decommissioning of future OSW actions by increasing congestion and delays at ports. However, vessel traffic would also be spread among multiple ports to ensure sufficient capacity exists at each port and in each waterway. Port utilization is also not expected to increase beyond what is currently allowed under land use regulations; therefore, port utilization that supports future OSW activities would not impact the construction, operation, and maintenance of existing and future undersea cables. Therefore, there would be **negligible** adverse impacts from increased port utilization for the construction, operation, and maintenance of existing and future undersea cables. | **Offshore:** Vessels used for the Project could impact installation and O&M of other undersea cables by increasing congestion and delays at ports. However, vessel traffic would also be spread among multiple ports to ensure sufficient capacity exists at each port and in each waterway. Port utilization is also not expected to increase beyond what is currently allowed under land use regulations; therefore, port utilization that supports the Proposed Action and Alternatives C through F would have **negligible** adverse impacts on existing and future undersea cables.<br>**Onshore:** Same as offshore impacts. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F; therefore, port utilization that supports Alternative G would have **negligible** adverse impacts on existing and future undersea cables.<br>**Onshore:** Same as offshore impacts. |
| Presence of structures: Allisions and navigation hazards | Constructed and permitted OSW COP projects are introducing 13 structures into the GAA. Other existing structures within and near the GAA that pose potential allision hazards include met buoys associated with OSW lease areas; and shoreline | Reasonably foreseeable non-OSW structures that could affect submarine cables have not been identified in the GAA. | See Section 3.17.2.6.2 for analysis. | See Section 3.17.2.11 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.21 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | developments such as docks, ports, and other commercial, industrial, and residential structures. Current activities could preclude future submarine cable placement in the GAA, although there are no known future cables identified to be placed within this area. Additionally, ongoing vessel traffic represents a risk for allisions with vessels used for construction of undersea cables. | | | | |
| Presence of structures: Space use conflicts | Submarine cables cross the GAA and are associated with a larger network of submarine cables that are present along the OCS. Constructed and permitted OSW COP projects are also introducing 13 structures into the GAA. Current activities could preclude future submarine cable placement in the GAA, although there are no known future cables identified to be placed within this area. | Reasonably foreseeable non-OSW structures have not been identified in the GAA. | See Section 3.17.2.6.2 for analysis. | See Section 3.17.2.11 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.21 for analysis of impacts. |
| Presence of structures: Transmission cable infrastructure | Seven submarine cable corridors cross cumulative lease areas. Constructed and permitted OSW COP projects are also introducing an estimated 163 miles of new offshore cable in the GAA. Current activities could preclude future submarine cable placement in the GAA, although there are no known future cables identified to be placed within this area. | Reasonably foreseeable non-OSW structures have not been identified in the GAA. | See Section 3.17.2.6.2 for analysis. | See Section 3.17.2.11 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.21 for analysis of impacts. |
| Traffic: Aviation | Military air traffic use the area, and government and other private aircraft could occasionally fly over the WEA for data collection and SAR operations. Aircraft are also used for scientific and academic surveys in marine environments. | Although no future non-OSW stationary structures were identified within the offshore GAA, aircraft would continue to be used to conduct scientific research studies as well as wildlife monitoring and preconstruction surveys. SAR operations could be expected to increase with any increase in vessel traffic. However, because vessel traffic volume associated with future non-OSW is not expected to increase appreciably, neither should SAR operations. Commercial air traffic could also be expected to increase with current trends. | Future OSW activities could result in increased air traffic due to the use of helicopters and other aircraft during construction, installation, O&M, and decommissioning of future wind projects. While the exact increase in future project-related flights is unknown, it is anticipated that future OSW activities would result in a small increase in flight traffic. Future OSW projects would be required to engage the FAA in flight planning to avoid impacts to civilian, commercial, government, and military aviation operations. With implementation of FAA-approved flight plans, impacts of the No Action Alternative on undersea cables would be **negligible** adverse. | **Offshore:** Aviation and air traffic impacts from offshore construction, O&M, and decommissioning of the Project would not coincide with areas in which undersea cables are located. While Alternatives C through F would require fewer Project-related helicopter trips due to the reduction in number of offshore elements, the effects of this IPF on undersea cables and pipelines would be **negligible** adverse under all Project alternatives.<br>**Onshore:** Same as offshore impacts. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Although Alternative G would require fewer Project-related helicopter trips due to the reduction in number of offshore elements, the effects of this IPF on undersea cables and pipelines would be **negligible** adverse under all Project alternatives.<br>**Onshore:** Same as offshore impacts. |
| Traffic: Vessels | Current vessel traffic in the region is described in Section 3.16.1. The GAA would continue to have numerous ports, and the | Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not | See Section 3.17.2.6.2 for analysis. | See Section 3.17.2.11 and Section 3.17.2.1, Table 3.17-1 for analysis of impacts. | See Section 3.17.2.21 for analysis of impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | extensive marine traffic related to constructed and permitted OSW COP projects, shipping, fishing, and recreation would continue to be important to the region's economy. Ongoing vessel traffic could lead to course changes of vessels used for undersea cable maintenance and installation and increased traffic along vessel transit routes. | anticipate vessel traffic to greatly increase over the next 30 years. Even with increased port visits by deep draft vessels and consistent generation of new vessel traffic by proposed barge routes and dredging demolition sites, this is still a relatively small adjustment when considering the whole of New England vessel traffic. | | | |
| Climate change | Climate change, influenced in part by GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters and sea level rise. | No future activities were identified within the GAA other than ongoing activities. | The effects of this IPF from the No Action Alternative would not impact undersea cables because undersea cables and cable placement are not impacted by ongoing or future climate change impacts. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource. | **Offshore:** The impacts of this IPF would not impact undersea cables for the Proposed Action and Alternatives C through F because climate change impacts do not have a measurable effect on undersea cables. This IPF would result in **negligible** adverse impacts because there would be no effect on this resource.<br>Same as offshore impacts. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in **negligible** adverse impacts because there would be no effect on this resource.<br>Same as offshore impacts. |

* Includes one constructed and permitted COP project within the undersea cables GAA: SFWF.

# Other Marine Uses: Land-Based Radar

**Table E2-18. Summary of Activities and the Associated Impact-Producing Factors for Other Marine Uses: Land-Based Radar**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases and discharges | Accidental releases and discharges of fuels and fluids have the potential to occur during vessel usage for permitted and built OSW COP projects, dredge material ocean disposal, fisheries use, marine transportation, military use, survey activities, and submarine cable line and pipeline laying activities. | Future accidental releases from offshore vessel usage, spills, and consumption would likely continue on a similar trend to ongoing activities. | The effects of this IPF from the No Action Alternative would not impact land-based radar because accidental releases and discharges would be limited in scope to the offshore and onshore areas occupied by future OSW activities and would not result in increased radar interference. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource. | **Offshore:** The effects of this IPF from the Proposed Action and Alternatives C through F would not impact land-based radar because accidental releases and discharges from the Project would be limited to the areas in which construction, O&M, and decommissioning are taking place and would not be located near land-based radar systems, nor would land-based radar systems be affected by accidental releases and discharges. While Alternatives C through F would require fewer Project-associated vessel trips, incrementally reducing the risk of accidental releases and discharges, the effects under all Project alternatives would be similar. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource.<br>**Onshore:** Same as offshore impacts. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. Although Alternative G would require fewer Project-associated vessel trips, incrementally reducing the risk of accidental releases and discharges, the effects under all Project alternatives would be similar. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource.<br>**Onshore:** Same as offshore impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Anchoring and new cable emplacement/maintenance | Impacts from this IPF have the potential to occur due to permitted and built OSW COP projects, to ongoing military use and survey, commercial, and recreational activities. These disturbances would be limited to local areas and are not expected to increase radar interference. | Impacts from anchoring could occur on a semiregular basis over the next 35 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. Cable emplacement/maintenance would be infrequent and short term. | Offshore energy facility new cable emplacement and maintenance of cables would involve increased vessel traffic, which could create increased radar interference. However, the impacts are expected to be small and short term because anchoring and cable emplacement/maintenance activities are short-term activities that require few vessels. On this basis, the effects of anchoring and new cable emplacement/maintenance on land-based radar under the No Action Alternative would be **negligible** adverse. | **Offshore:** Cable construction associated with the Proposed Action and Alternatives C through F could result in increased vessel traffic, which could create increased radar interference. However, the impacts are expected to be small and short term in duration because anchoring and cable emplacement activities are short term and infrequent activities that require few vessels. Impacts under Alternatives C through F would be slightly reduced due to smaller Project footprints and fewer offshore structures, but effects would be similar under all Project alternatives. On this basis, the effects of anchoring and new cable emplacement/maintenance on land-based radar under the Proposed Action and Alternatives C through F during Project construction, O&M, and decommissioning would be **negligible** adverse.<br>Up to 2,961 acres could be affected by anchoring/mooring activities during OSW energy development within the GAA in addition to the Proposed Action and Alternatives C through F. However, the impacts are expected to be small and short term. Therefore, the cumulative impacts associated with the Proposed Action and Alternatives C through F when combined with past, present, and reasonably foreseeable activities would be similar to those impacts described under the No Action Alternative and would be **negligible** adverse. | **Offshore: S**imilar impacts to the Proposed Action and Alternatives C through F. On this basis, the effects of anchoring and new cable emplacement/maintenance on land-based radar under Alternative G during Project construction, O&M, and decommissioning would be **negligible** adverse.<br>Up to 2,093 acres could be affected by anchoring/mooring activities during OSW energy development within the GAA under Alternative G. However, the impacts are expected to be short term. Therefore, the cumulative impacts of Alternative G when combined with past, present, and reasonably foreseeable activities would be similar to those impacts described under the Proposed Action and would be **negligible** adverse. |
| | | | | **Onshore:** Same as offshore impacts. | **Onshore:** Same as offshore impacts. |
| Light | Constructed and permitted OSW COP projects are introducing 81 lighted structures into the GAA, as well as lighted vessels. Other impacts from lighting include light associated with military, commercial, or construction vessel traffic but are not expected to result in radar interference. | No future activities were identified within the GAA other than ongoing activities. | The effects of this IPF from the No Action Alternative would not impact land-based radar because light from future OSW activities would not affect radar systems. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource. | **Offshore:** Light from construction, O&M, and decommissioning of the Proposed Action and Alternatives C through F would not affect radar systems. This IPF would result in a **negligible** adverse effect on the operation and effectiveness of land-based radar systems because there would be no effect on this resource.<br>The cumulative effects of this IPF do not impact land-based radar and are therefore **negligible** adverse.<br>Although Alternatives C through F would require fewer construction vessel trips and | **Offshore:** Although Alternative G would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | |
| | | | | **Onshore:** Same as offshore impacts. | **Onshore:** Same as offshore impacts. |
| Noise | Noise impacts are expected from OSW and non-OSW construction and vessel traffic but are not expected to result in radar interference. | No future activities were identified within the GAA other than ongoing activities. | The effects of this IPF from the No Action Alternative would not impact land-based radar because noise from future OSW activities would not affect radar systems. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource. | **Offshore:** Airborne noise from construction of the Proposed Action would have a **negligible** adverse effect on land-based radar systems because noise from future OSW activities would not affect radar systems.<br>Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | **Offshore:** Although Alternative G would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. |
| | | | | **Onshore:** Same as offshore impacts. | **Onshore:** Same as offshore impacts. |
| Port utilization | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance. Impacts from these activities would be short term but could result in increased radar interference. | No future activities were identified within the GAA other than ongoing activities. | There could be an increase in vessel use at ports associated with the No Action Alternative. However, vessel traffic would also be spread among multiple ports to ensure sufficient capacity exists at each port and in each waterway. Port utilization is also not expected to increase beyond what is currently allowed under land use regulations; therefore, there would be **negligible** adverse impacts from increased port utilization on land-based radar. | **Offshore:** Various ports would be improved to support the Proposed Action (see Section 3.14). These improvements would occur within the boundaries of existing port facilities, would be similar to existing activities at the existing ports, and would support state strategic plans and local land use goals for the development of waterfront infrastructure. The number of construction vessels associated with the Proposed Action would increase, which could result in vessel congestion at ports, but this would be a short-term effect. An increase in vessel traffic could result in increased radar interference. However, vessel traffic would also be spread among multiple ports to ensure sufficient capacity exists at each port and in each waterway. Because port utilization is not expected to increase beyond what is currently allowed under land use regulations, port utilization is expected to have a **negligible** adverse effect on land-based radar. Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | **Offshore:** Although Alternative G would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. |
| | | | | **Onshore:** Same as offshore impacts. | **Onshore:** Same as offshore impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Presence of structures: Navigation hazards | Constructed and permitted OSW COP projects are introducing 81 structures into the GAA. Wind developments in the direct line-of-sight with, or extremely close to, radar systems can cause clutter and interference. | Reasonably foreseeable non-OSW structures proposed for construction in the lease areas that could affect radar systems have not been identified. | See Section 3.17.2.3.2 for analysis. | See Section 3.17.2.1, Table 3.17-1 and Section 3.17.2.8 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Traffic: Aviation | Military air traffic use the area, and government and other private aircraft could occasionally fly over the WEA for data collection and SAR operations. Aircraft are also used for scientific and academic surveys in marine environments. | Although no future non-OSW stationary structures were identified within the offshore GAA, aircraft would continue to be used to conduct scientific research studies as well as wildlife monitoring and preconstruction surveys. SAR operations could be expected to increase with any increase in vessel traffic. However, because vessel traffic volume associated with future non-OSW is not expected to increase appreciably, neither should SAR operations. Commercial air traffic could also be expected to increase with current trends. | Future OSW activities without the Proposed Action could result in increased air traffic due to the use of helicopters and other aircraft during construction, installation, O&M, and decommissioning of future wind projects. While the exact increase in future project-related flights is unknown, it is anticipated that future OSW activities would result in a small increase in flight traffic. Future OSW projects would be required to engage the FAA in flight planning to avoid impacts to civilian, commercial, government, and military aviation operations. With implementation of FAA-approved flight plans, impacts of the No Action Alternative on land-based radar would be **negligible** adverse. | **Offshore:** The Proposed Action would result in an increase in air traffic related to construction and installation of offshore Project elements. Two helicopter trips per day are anticipated per day during construction, with a total flight time of 8,832 hours, or approximately 4,416 hours per year over the 2-year construction period. Extrapolating from nationwide statistics cited in Section 3.17.2.2.1, helicopter flights for Project construction would represent a 63% increase in annual helicopter flight hours and a 7% increase in general aviation flight hours in the GAA during Project construction. O&M of the Proposed Action would result in a 0.01% increase in general aviation in the GAA. A helicopter route plan would be developed to meet industry guidelines and best practices in accordance with FAA guidance. The addition of one to two helicopter trips per day would have a **negligible** adverse impact on land-based radar in the GAA.<br>The Proposed Action would result in an average 1% increase in general aviation in the GAA over a 32-year construction, installation, O&M, and decommissioning period, with reasonably foreseeable future actions anticipated to have similar impacts in scale and duration. On the basis of a 1% increase in general aviation in the GAA, the cumulative effects of this IPF on land based radar would be **negligible** adverse.<br>Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | **Offshore:** Although Alternative G would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. |
| | | | | **Onshore:** Same as offshore impacts. | **Onshore:** Same as offshore impacts. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Traffic: Vessels | Current vessel traffic in the region is described in Section 3.16.1. The GAA would continue to have numerous ports and extensive marine traffic related to constructed and permitted OSW COP projects, shipping, fishing, and recreation. WTG spacing that allows more space for vessels to navigate would reduce potential interference on radar systems. | Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not anticipate vessel traffic to greatly increase over the next 30 years. Even with increased port visits by deep draft vessels and consistent generation of new vessel traffic by proposed barge routes and dredging demolition sites, this is still a relatively small adjustment when considering the whole of New England vessel traffic | See Section 3.17.2.3.2 for analysis. | See Section 3.17.2.1, Table 3.17-1 and Section 3.17.2.8 for analysis of impacts. | See Sections 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Climate change | Climate change has resulted in a measurable increase in annual precipitation on the East Coast. | Sea level rise and storm severity/frequency would increase due to the effects of climate change. | Future OSW activities could result in construction activities that increase GHG emissions. Increased GHG emissions could contribute to climate change impacts. Climate change has resulted in a measurable increase in annual precipitation on the East Coast. However, the construction of future OSW facilities would ultimately help slow the negative effects of climate change by redistributing some of the East Coast's energy generation to renewable sources. On this basis, the effects of climate change on land-based radar under the No Action Alternative would be **negligible** adverse. | **Offshore:** The Proposed Action could result in construction, O&M and decommissioning activities that increase GHG emissions. Increased GHG emissions could contribute to climate change impacts. However, the beneficial impacts to climate change would be increased due shifting energy sources from nonrenewable to renewable sources, which would help offset additional future additional negative effects of climate change. Climate change impacts from the Proposed Action would not impact land-based radar because the construction, operation, and maintenance of land-based radar systems is not affected by climate change that can be linked to the Proposed Action. Therefore, the effects of climate change on land-based radar under the Proposed Action would be **negligible** adverse.<br>Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | **Offshore:** Although Alternatives G would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. |
| | | | | **Onshore:** Same as offshore impacts. | **Onshore:** Same as offshore impacts. |

* Includes three constructed and permitted COP projects within the land-based radar GAA: Block Island, SFWF, and Vineyard Wind 1.

## Other Marine Uses: Scientific Research and Surveys

**Table E2-19**. **Summary of Activities and the Associated Impact-Producing Factors for Other Marine Uses: Scientific Research and Surveys**

| Associated IPFs: Sub-IPFs | Ongoing Activities | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases and discharges | Accidental releases and discharges of fuels and fluids have the potential to occur during vessel usage for permitted and built OSW COP projects, dredge material ocean disposal, fisheries use, marine transportation, military use, survey activities, and submarine cable line and pipeline laying activities. | Future accidental releases from offshore vessel usage, spills, and consumption would likely continue on a similar trend to ongoing activities. | Fuels and oils would be required for construction and installation, O&M, and decommissioning of future OSW activities. In the event of a spill or release during construction and installation activities, offshore water quality would be degraded. OSRPs would be required for all future OSW projects, which includes processes for rapid spill response, containment, cleanup, and other measures that would help minimize impacts on water quality from spills. Releases during construction of future OSW activities during all phases of project construction would generally be localized and short term, resulting in little change to water quality.<br>In the event of a spill, water quality could be temporarily impacted, which could alter water quality in the vicinity of the spill. This could alter results of scientific surveys that are water quality dependent. However, an OSRP has been prepared for the Project and includes processes for rapid spill response, containment, cleanup, and other measures that would help minimize impacts on water quality from spills. Therefore, the effects of accidental releases and discharges on scientific research and surveys from future OSW activities without the Proposed Action would be **negligible** adverse. | **Offshore:** Fuels and oils would be required for Proposed Action offshore construction and installation, O&M, and decommissioning equipment, vessels, and infrastructure. In the event of a spill or release, offshore water quality would be degraded. As described in Section 3.21.1.2, the likelihood of a spill due to construction and installation activities and weather events is low (once per 1,000 years). However, water quality could be temporarily impacted in the vicinity of the spill. This could alter results of scientific surveys that are water quality dependent. An OSRP has been prepared for the Project and includes processes for rapid spill response, containment, cleanup, and other measures that would help minimize impacts on water quality from spills.<br>Therefore, the effects of accidental releases and discharges on scientific research and surveys from the Proposed Action would be **negligible** adverse.<br>Reasonably foreseeable activities could also result in accidental releases and discharges, although those projects would be subject to the same minimization measures as the RWF. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would be **negligible** adverse.<br>Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse.<br>**Onshore:** The construction and installation of onshore Project components would not impact scientific research and surveys because accidental releases and discharges would be limited to an onshore construction footprint and scientific research and surveys | **Offshore:** Although Alternative G would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse.<br>**Onshore:** The construction and installation of onshore Project components would not impact scientific research and surveys because accidental releases and discharges would be limited to an onshore construction footprint and scientific research and surveys would occur offshore. This IPF would result in a **negligible** adverse impact. |

| Associated IPFs: Sub-IPFs | Ongoing Activities | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | would occur offshore. This IPF would result in a **negligible** adverse impact. | |
| Anchoring and new cable emplacement/maintenance | Impacts from this IPF have the potential to occur due to permitted and built OSW COP projects, ongoing military use and survey, commercial, and recreational activities. These activities potentially increase navigational complexity and vessel traffic but are expected to minimally impact scientific research and surveys. | Impacts from anchoring could occur on a semiregular basis over the next 35 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. Cable emplacement/maintenance would be infrequent and short term. | See Section 3.17.2.5.2 for analysis. | See Section 3.17.2.1, Table 3.17-1 and Section 3.17.2.10 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Light | Constructed and permitted OSW COP projects are introducing 83 lighted structures into the GAA, as well as lighted vessels. Other impacts from lighting on scientific research and surveys include light associated with non-OSW military, commercial, or construction vessel traffic. Ocean vessels have an array of lights, including navigational lights and deck lights. Offshore buoys and towers emit low-intensity light. Onshore structures, including houses and ports, emit substantially more light on an ongoing basis. These lighting sources could change species' behavior, which could impact the results of scientific research and surveys. | Future activities with the potential to result in lighting impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Light pollution from vessel traffic would continue at the current intensity along the Northeast coast, with a slight increase due to population increase and development over time. Light from onshore structures is expected to gradually increase in line with human population growth along the coast, with minimal offshore impacts. | See Section 3.17.2.5.2 for analysis. | See Section 3.17.2.1, Table 3.17-1 and Section 3.17.2.10 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Noise | Noise impacts are expected from OSW and non-OSW construction and vessel traffic. Construction occurs frequently in nearshores of populated areas in New England and the Mid-Atlantic but infrequently offshore. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this IPF consist of constructed and permitted OSW COP projects, commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels. | Noise from construction near shorelines is expected to gradually increase in line with human population growth along the coast of the GAA for this resource. Planned new barge routes and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain. | Construction and installation of future OSW projects would result in temporary increases in construction and decommissioning noise. There would be low levels of operational noise as part of future OSW projects. Construction noise has the potential to interfere with scientific research and surveys if such surveys are sensitive to noise impacts. However, construction noise levels are expected to be below regulatory thresholds and would be short term in duration. Operational noise impacts are expected to be very minimal and would also be below regulatory thresholds. Therefore, noise would have a **negligible** adverse impact on scientific research and surveys. | **Offshore and Onshore:** Construction and installation of the Proposed Action would result in a temporary increase in construction noise. O&M and decommissioning of the Proposed Action would result in long-term, permanent low levels of operational noise and temporary noise during decommissioning. These noise sources have the potential to interfere with scientific research and surveys if such surveys are sensitive to noise impacts. However, because NMFS anticipates that construction and O&M of the Project would result in curtailment of scientific research and surveys in the GAA, noise would have a **negligible** adverse impact on scientific research and surveys.<br>Reasonably foreseeable activities would also increase noise in the area, which could interfere with scientific research and surveys. However, reasonably foreseeable future actions would also result in curtailment of scientific research and surveys in the RI/MA | **Offshore and Onshore:** Although Alternative G would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. |

| Associated IPFs: Sub-IPFs | Ongoing Activities | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | WEA as additional wind projects are constructed. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would be **negligible** adverse.<br>Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | |
| Port utilization | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance. Impacts from these activities would be short term and could include congestion in ports, delays, and changes in port usage. The increased activity could increase navigational complexity and vessel traffic, which could impede scientific research and studies. | Ports would need to perform maintenance and upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host larger deep draft vessels as they continue to increase in size. Impacts would be short term and could include congestion in ports, delays, and changes in port usage by some fishing or recreational vessel operators. | Various ports would be improved to support future OSW development within the GAA (see Section 3.14). These improvements would occur within the boundaries of existing port facilities, would be similar to existing activities at the existing ports, and would support state strategic plans and local land use goals for the development of waterfront infrastructure. The number of construction vessels would increase due to future OSW activities without the Proposed Action, which could result in delays and congestion at ports that could lead to potential conflicts with scientific research vessels due to increased port activity. Navigational hazards and collision risks at ports and in transit routes would be reduced as construction is completed, and all navigation hazards and collision risks would be gradually eliminated during decommissioning as offshore WTGs are removed. However, vessel traffic would also be spread among multiple ports to ensure sufficient capacity exists at each port and in each waterway. Therefore, port utilization is expected to have a **negligible** adverse effect on scientific research and surveys. | **Offshore and Onshore:** Various ports would be improved to support the Proposed Action (see Section 3.14). These improvements would occur within the boundaries of existing port facilities, would be similar to existing activities at the existing ports, and would support state strategic plans and local land use goals for the development of waterfront infrastructure. Because port utilization is not expected to increase beyond what is currently allowed under land use regulations, port utilization that supports the Proposed Action would not impact scientific research and surveys. The number of construction and operational vessels would increase due to the Proposed Action, which could result in delays and congestion at ports that could lead to conflicts with scientific and research vessels. However, vessel traffic would also be spread among multiple ports to ensure sufficient capacity exists at each port and in each waterway. Therefore, port utilization is expected to have a **negligible** adverse effect on scientific research and surveys.<br>Reasonably foreseeable future actions would also result in improvements at various ports to support future OSW projects (see EIS Appendix E). These improvements would occur within the boundaries of existing port facilities, would be similar to existing activities at the existing ports, and would also support state strategic plans and local land use goals for the development of waterfront infrastructure. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and | **Offshore and Onshore:** Although Alternative G would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. |

| Associated IPFs: Sub-IPFs | Ongoing Activities | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | reasonably foreseeable activities would be **negligible** adverse.<br>Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | |
| Presence of structures: Navigation hazards | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. NOAA has concluded that, within OSW facility areas, survey operations would be curtailed, if not eliminated, under current vessel capacities and monitoring protocols. Specifically, coordinators of large vessel survey operations or operations deploying mobile survey gear have currently determined that activities within OSW facilities are not within their safety and operational limits. | Reasonably foreseeable non-OSW activities would not implement stationary structures within the open ocean environment that would pose navigational hazards and raise the risk of allisions for survey vessels and collisions for survey aircraft. | See Section 3.17.2.5.2 for analysis. | See Section 3.17.2.1, Table 3.17-1 and Section 3.17.2.10 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |
| Traffic: Aviation | Military air traffic use the area and government and other private aircraft could occasionally fly over the WEA for data collection and SAR operations. Aircraft are also used for scientific and academic surveys in marine environments. Some vessels or low-flying aircraft may be required to alter course to avoid WTGs associated with constructed and permitted OSW COP projects. NOAA policy advises survey vessels to remain at least 1 mile from fixed structures if possible. | Although no future non-OSW stationary structures were identified within the offshore GAA, aircraft would continue to be used to conduct scientific research studies as well as wildlife monitoring and preconstruction surveys. SAR operations could be expected to increase with any increase in vessel traffic. However, because vessel traffic volume associated with future non-OSW is not expected to increase appreciably, neither should SAR operations. Commercial air traffic could also be expected to increase with current trends. | Future OSW activities without the Proposed Action could result in increased air traffic due to the use of helicopters and other aircraft during construction and installation, O&M, and decommissioning of future wind projects. While the exact increase in future project-related flights is unknown, it is anticipated that future OSW activities would result in a small increase in flight traffic. Future OSW projects would be required to engage the FAA in flight planning to avoid impacts to civilian, commercial, government, and military aviation operations. With implementation of FAA-approved flight plans, impacts of the No Action Alternative on scientific research and surveys would be **negligible** adverse. | **Offshore and Onshore:** Construction and installation of the Proposed Action would result in a 7% increase in general aviation in the GAA. O&M of the Proposed Action would result in a 0.01% increase in general aviation in the GAA. Please refer to Section 3.17 for analysis of the Project's construction and installation impacts. On the basis of the estimated increase in general aviation in the GAA, the effects of this IPF on scientific research and surveys under the Proposed Action would be **negligible** adverse, as the 7% increase in general aviation flight hours is not anticipated to impact air-based scientific research and surveys.<br>Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | **Offshore and Onshore:** Although Alternative G would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. |
| Traffic: Vessels | Current vessel traffic in the region is described in Section 3.16.1. The GAA would continue to have numerous ports and extensive marine traffic related to constructed and permitted OSW COP projects, shipping, fishing, and recreation. | Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not anticipate vessel traffic to greatly increase over the next 30 years. Even with increased port visits by deep draft vessels and | See Section 3.17.2.5.2 for analysis. | See Section 3.17.2.1, Table 3.17-1 and Section 3.17.2.10 for analysis of impacts. | See Section 3.17.2.1, Table 3.17-1 for analysis of impacts. |

|---|---|---|---|---|---|
| | These sources of vessel traffic may lead to course changes of scientific and research vessels or increase risk of collision. | consistent generation of new vessel traffic by proposed barge routes and dredging demolition sites, this is still a relatively small adjustment when considering the whole of New England vessel traffic. | | | |
| Climate change | Climate change, influenced in part by GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters and sea level rise. | No future activities were identified within the GAA other than ongoing activities. | The ongoing effects of global climate change are expected to adversely affect many marine resources that are the subject ongoing survey and research efforts. Climate change could influence the planning and objectives of future scientific research and surveys but would not be expected to have a measurable effect on their implementation. Therefore, the effects of this IPF on scientific surveys and research would be **negligible** adverse. | **Offshore and Onshore:** The ongoing effects of global climate change are expected to adversely affect many marine resources that are the subject of ongoing survey and research efforts. Climate change could influence the planning and objectives of future scientific research and surveys but would not be expected to have a measurable effect on their implementation. Therefore, the effects of this IPF on scientific surveys and research would be **negligible** adverse.<br>Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | **Offshore and Onshore:** Although Alternative G would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. |

* Includes all constructed and permitted COP projects within the scientific survey GAA: Block Island, SFWF, Vineyard Wind 1, and Coastal Virginia Offshore Wind.

## Other Marine Uses: Offshore Energy Uses

Affected environment: The OCS near the Project is currently experiencing active leasing and exploration in support of OSW energy development. EIS Appendix E provides a list of known and anticipated OSW project and wind energy leases existing in the area that could lead to additional wind farm development. BOEM anticipates that developers could continue to propose OSW energy projects near the Project. The trend in increased wind farm development is anticipated to continue on the OCS. Several tidal energy projects have been implemented in the region and several are in the planning stages (see Appendix E of the COP). Tidal energy projects are typically located in the nearshore environment where landforms constrict tidal water passage, thereby increasing the velocity of tidal currents. These landforms exist in Narragansett Bay within the GAA; however, more detailed studies are needed to assess sites and determine economic viability for tidal energy uses (Robichaud et al. 2012). The Town of Edgartown has pursued developing a tidal energy site in the Muskeget Channel between Martha's Vineyard and Nantucket Island since 2007. It has operated as a test site and is usable for a wide range of testing. To date, over $2 million has been expended on resource, benthic, sediment, marine mammal, and other studies. The Bourne Tidal Test Site is located on Cape Cod Canal has been used for small tidal energy demonstration projects (New England Marine Energy Development System 2017).

**Table E2-20. Summary of Activities and the Associated Impact-Producing Factors for Other Marine Uses: Offshore Energy Uses**

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| Accidental releases and discharges | Accidental releases and discharges of fuels and fluids have the potential to occur during vessel usage for permitted and built OSW COP projects, dredge material ocean disposal, fisheries use, marine transportation, military use, survey | Future accidental releases from offshore vessel usage, spills, and consumption would likely continue a similar trend to ongoing activities. | Construction and operation of offshore energy projects are expected between 2021 and 2030. This use is not carried forward for stand-alone cumulative analysis because the impact of OSW is already evaluated as part of all other IPFs and uses. | **Offshore:** Because offshore energy projects occur within individual lease areas, there would be no opportunity for the RWF to directly overlap or substantially interfere with other renewable energy projects. Therefore, accidental releases and discharge associated with the RWF would not impact other offshore | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |

|---|---|---|---|---|---|
| | temporary. Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this IPF consist of constructed and permitted OSW COP projects, commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels. | | The reader is referred to other subsections for evaluation of the impacts of future OSW on marine uses. | Proposed Action. Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | |
| Port utilization | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance. Impacts from these activities would be short term and could include congestion in ports, delays, and changes in navigation patterns at nearby airports. The increased activity could cause potential conflicts with other offshore energy uses. | Ports would need to perform maintenance and upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host larger deep draft vessels as they continue to increase in size. Impacts would be short term and could include congestion in ports, delays, changes in port usage by some fishing or recreational vessel operators, and changes in navigation patterns. | Construction and operation of offshore energy projects are expected between 2021 and 2030. This use is not carried forward for stand-alone cumulative analysis because the impact of OSW is already evaluated as part of all other IPFs and uses.<br>The reader is referred to other subsections for evaluation of the impacts of future OSW on marine uses. | **Offshore:** If construction time frames with other OSW energy project overlap, there could be increased impacts to construction ports. Such impacts are not anticipated to affect construction timelines or alter the layouts of other renewable energy projects. For this reason, impacts are deemed **negligible** adverse for the Proposed Action. Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |
| Presence of structures: Navigation hazards | Constructed and permitted OSW COP projects are introducing 83 structures into the GAA. Other stationary structures are limited in the open ocean environment of the GAA and include met buoys associated with site assessment activities. Navigation complexity associated with existing structures could cause potential conflicts with other offshore energy uses. | Reasonably foreseeable non-OSW activities would not implement stationary structures within the open ocean environment that would pose navigational hazards and raise the risk of allisions for survey vessels and collisions for survey aircraft. | Construction and operation of offshore energy projects are expected between 2021 and 2030. This use is not carried forward for stand-alone cumulative analysis because the impact of OSW is already evaluated as part of all other IPFs and uses.<br>The reader is referred to other subsections for evaluation of the impacts of future OSW on marine uses. | **Offshore:** Because offshore energy projects occur within individual lease areas, there would be no opportunity for the RWF to directly overlap or substantially interfere with other renewable energy projects. Therefore, this IPF would result in a **negligible** adverse impact for the Proposed Action. Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. On the basis of the estimated increase in general aviation in the GAA, the effects of this IPF on offshore energy uses under the Proposed Action would be **negligible** adverse for the Proposed Action. Although Alternatives C through F would require fewer construction vessel and helicopter trips and WTGs and would reduce the overall duration of construction | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | | activities relative to the Proposed Action, impacts would also be **negligible** adverse. | |
| Traffic: Vessels | Current vessel traffic in the region is described in Section 3.16.1. The GAA would continue to have numerous ports and extensive marine traffic related to constructed and permitted OSW COP projects, shipping, fishing, and recreation. These sources of vessel traffic may increase navigation, which could cause potential conflicts with other offshore energy uses. | Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not anticipate vessel traffic to greatly increase over the next 30 years. Even with increased port visits by deep draft vessels and consistent generation of new vessel traffic by proposed barge routes and dredging demolition sites, this is still a relatively small adjustment when considering the whole of New England vessel traffic | Construction and operation of offshore energy projects are expected between 2021 and 2030. This use is not carried forward for stand-alone cumulative analysis because the impact of OSW is already evaluated as part of all other IPFs and uses.<br>The reader is referred to other subsections for evaluation of the impacts of future OSW on marine uses. | **Offshore:** If construction or O&M time frames with other OSW energy project overlap, there could be increased navigation risk due to an increase in vessels in the GAA. Such impacts are not anticipated to affect construction timelines or alter the layouts of other renewable energy projects. For this reason, adverse impacts to other renewable energy projects are deemed **negligible** adverse for the Proposed Action. Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |
| Climate change | Climate change, influenced in part by GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters and sea level rise. | No future activities were identified within the GAA other than ongoing activities. | Construction and operation of offshore energy projects are expected between 2021 and 2030. This use is not carried forward for stand-alone cumulative analysis because the impact of OSW is already evaluated as part of all other IPFs and uses.<br>The reader is referred to other subsections for evaluation of the impacts of future OSW on marine uses. | **Offshore:** Climate change impacts from the Proposed Action would not have a measurable effect on other offshore energy uses. This IPF would result in a **negligible** adverse impact for the Proposed Action. Although Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | **Offshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |

* Includes all constructed and permitted COP projects that occur within the offshore energy uses GAA: Block Island, SFWF, Vineyard Wind 1, and Coastal Virginia Offshore Wind.

## Other Marine Uses: Marine Mineral Resources and Dredged Material Disposal

<u>Affected environment:</u> BOEM's Marine Minerals Program manages non-energy minerals (primarily sand and gravel) in federal waters of the OCS and leases access to these resources to target shoreline erosion, beach renourishment, and restoration projects. At this time, there are no active or requested BOEM leases near the Project. The closest active BOEM lease is offshore of New Jersey, approximately 162 miles from the Project (BOEM 2018). One USACE borrow area (7A) is located offshore the town of Wainscott, in the vicinity of the RWEC.

The EPA designates and manages dredged material disposal sites, and the USACE permits the disposal of material in the sites. One active disposal site, the Rhode Island Sound Disposal Site, is located in the GAA approximately 3 miles east of Block Island, Rhode Island, and 10 miles west of the western boundary of the proposed RWF. No inactive or closed disposal sites are located in the GAA.

Increased shoreline erosion and coastal damage from storms has led to increased demand for sand resources in recent years.

**Table E2-21**. **Summary of Activities and the Associated Impact-Producing Factors for Other Marine Uses: Marine Mineral Resources and Dredged Material Disposal**

| **Associated IPFs:**<br>**Sub-IPFs** | **Ongoing Activities*** | **Future Non–Offshore Wind Activities Intensity/Extent** | **Future Offshore Wind Activities Intensity/Extent** | **Proposed Action and Alternatives C through F** | **Alternative G (Preferred Alternative)** |
|---|---|---|---|---|---|
| Accidental releases and discharges | Accidental releases and discharges of fuels and fluids have the potential to occur during vessel usage for permitted and built OSW COP projects, dredge material ocean disposal, fisheries use, marine transportation, military use, survey activities, and submarine cable line and pipeline laying activities. | Future accidental releases from offshore vessel usage, spills, and consumption would likely continue on a similar trend to ongoing activities. | Fuels and oils would be required for construction, installation, O&M, and decommissioning of future OSW projects. In the event of a spill or release during construction and installation activities, offshore water quality would be degraded. OSRPs would be required for all future OSW projects, which includes processes for rapid spill response, containment, cleanup, and other measures that would help minimize impacts on water quality from spills. Releases during construction of future OSW projects during all phases of project construction would generally be localized and short term, resulting in little change to water quality.<br>In the event of a spill, marine mineral resources could potentially be impacted if such resources are susceptible to harm from contaminants, although the impacts would be very minimal. Therefore, the effects of vessel traffic on marine mineral resources and dredged material disposal under the No Action Alternative would be **negligible** adverse. | **Offshore and Onshore:** Fuels and oils would be required for Proposed Action offshore construction and installation, O&M, and decommissioning equipment, vessels, and infrastructure. In the event of a spill or release during construction and installation activities, offshore water quality would be degraded. As described in Section 3.21.1.2, the likelihood of a spill due to construction and installation activities and weather events is low (once per 1,000 years). An OSRP has been prepared for the Project and includes processes for rapid spill response, containment, cleanup, and other measures that would help minimize impacts on water quality from spills. A release during construction and installation of the Proposed Action would generally be localized and short term, resulting in little change to water quality.<br>In the event of a spill, marine mineral resources could potentially be impacted if such resources are susceptible to harm from contaminants, although the impacts would be very minimal. Therefore, the effects of accidental releases and discharges on marine mineral resources and dredged material disposal under the Proposed Action would be **negligible** adverse. Reasonably foreseeable activities could also result in accidental releases and discharges, although those projects would be subject to the same minimization measures as the RWF. Therefore, the cumulative impacts associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would be **negligible** adverse.<br>Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall footprint and duration of construction activities, but effects would also be **negligible** adverse. | **Offshore and Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |
| New cable emplacement/maintenance | Impacts from this IPF have the potential to occur due to permitted and built OSW COP projects, military use and survey, and commercial and recreational activities. These disturbances would be local and limited to emplacement corridors. | Impacts from anchoring could occur on a semiregular basis over the next 35 years due to offshore military operations, survey activities, commercial vessel traffic, and/or recreational vessel traffic. Cable emplacement/maintenance would be infrequent and short term. | Future offshore cable installation could prevent future marine mineral extraction activities where project footprints overlap with extraction areas (typically within 8 miles of the shoreline). Therefore, only a portion of new OSW cables could potentially overlap extraction areas. Additionally, future projects would avoid identified borrow areas by | **Offshore and Onshore:** Because marine mineral resources and EPA dredged material disposal sites are located outside the GAA, Project anchoring and new cable emplacement/maintenance would result in a **negligible** adverse impact for the Proposed Action. Although Alternatives C through F would require fewer construction vessel trips and | **Offshore and Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | | | consulting with the BOEM Marine Minerals Program and the USACE before approving OSW cable routes. Therefore, the effects of anchoring and new cable emplacement/maintenance under the No Action Alternative would be **negligible** adverse. | WTGs and would reduce the overall duration of construction activities relative to the Proposed Action, impacts would also be **negligible** adverse. | |
| Light | Constructed and permitted OSW COP projects are introducing 13 lighted structures into the GAA, as well as lighted vessels. Impacts from lighting on offshore energy uses also include light associated with military, commercial, or construction vessel traffic. Ocean vessels have an array of lights, including navigational lights and deck lights. Offshore buoys and towers emit low-intensity light. Onshore structures, including houses and ports, emit substantially more light on an ongoing basis. Impacts are expected to be minimal. | Future activities with the potential to result in lighting impacts include construction and operation of undersea transmission lines, gas pipelines, and other submarine cables (e.g., telecommunications); marine minerals use and ocean-dredged material disposal; military use; marine transportation; fisheries use and management; and oil and gas activities. Light pollution from vessel traffic would continue at the current intensity along the Northeast coast, with a slight increase due to population increase and development over time. Light from onshore structures is expected to gradually increase in line with human population growth along the coast, with minimal offshore impacts. | The effects of this IPF from the No Action Alternative would not impact marine mineral resources and dredged material disposal because light from future OSW activities would not affect marine mineral resources and dredged material disposal sites or activities. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource. | **Offshore and Onshore:** The effects of this IPF from the Proposed Action to marine mineral resources and dredged material disposal would be **negligible** adverse because marine mineral resources and EPA dredged material disposal sites are located outside the GAA.<br>Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall footprint, duration of construction activities, but effects would also be **negligible** adverse. | **Offshore and Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |
| Noise | Noise impacts are expected from OSW and non-OSW construction and vessel traffic. Construction occurs frequently in nearshores of populated areas in New England and the Mid-Atlantic but infrequently offshore. The intensity and extent of noise from construction is difficult to generalize, but impacts are local and temporary. Vessel noise occurs offshore and more frequently near ports and docks. Ongoing activities that contribute to this IPF consist of constructed and permitted OSW COP projects, commercial shipping, recreational and fishing vessels, and scientific and academic research vessels. Vessel noise is anticipated to continue at or near current levels. | Noise from construction near shorelines is expected to gradually increase in line with human population growth along the coast of the GAA for this resource. Planned new barge routes and dredging disposal sites would generate vessel noise when implemented. The number and location of such routes are uncertain. | The effects of this IPF from the No Action Alternative would not impact marine mineral resources and dredged material disposal because noise from future OSW activities would not affect marine mineral resources and dredged material disposal. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource. | **Offshore and Onshore:** The effects of this IPF from the Proposed Action to marine mineral resources and dredged material disposal would be **negligible** adverse because marine mineral resources and EPA dredged material disposal sites are located outside the GAA.<br>Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall footprint, duration of construction activities, but effects would also be **negligible** adverse. | **Offshore and Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |
| Port utilization | Constructed and permitted OSW COP projects are using nearby ports to support construction and O&M activities. The major ports in the United States are seeing increased vessel visits, as vessel size also increases. Ports are also experiencing continual upgrades and maintenance. | Ports would need to perform maintenance and upgrades to ensure that they can still receive the projected future volume of vessels visiting their ports and be able to host larger deep draft vessels as they continue to increase in size. Impacts would be short term and could include congestion in ports, delays, changes in | The effects of this IPF from the No Action Alternative would be **negligible** adverse on marine mineral resources and dredged material disposal because port utilization and potential increased vessel traffic resulting from the No Action Alternative are not | **Offshore and Onshore:** Various ports would be improved to support the Proposed Action (see Section 3.14). The number of construction and maintenance vessels associated with the Proposed Action would increase which could result in vessel congestion at ports and potential collision risk with marine mineral | **Offshore and Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |

| Associated IPFs:<br>Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | Impacts from these activities would be short term and could include congestion in ports, delays, and changes in navigation patterns. | port usage by some fishing or recreational vessel operators, and changes in navigation patterns. | expected to overlap with BOEM lease areas or EPA dredged material disposal sites. | resource or dredging vessels leaving or returning to ports, but this would be a minimal increase in vessel traffic. Also, vessel traffic would also be spread among multiple ports to ensure sufficient capacity exists at each port and in each waterway. Therefore, port utilization is expected to have a **negligible** adverse effect on marine mineral resources and dredged material disposal.<br>Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall footprint and duration of construction activities, but effects would also be **negligible** adverse. | |
| Presence of structures: Navigation hazards | Constructed and permitted OSW COP projects are introducing 13 structures into the GAA. Other existing stationary structures are limited in the open ocean environment of the GAA, and include met buoys associated with site assessment activities. Navigation complexity associated with existing structures could cause potential conflicts with other marine activities. | Reasonably foreseeable non-OSW activities would not implement stationary structures within the open ocean environment that would pose navigational hazards and raise the risk of allisions for survey vessels and collisions for survey aircraft. | Future offshore WTGs and OSSs could prevent future marine mineral extraction activities where project footprints overlap with extraction areas. However, this is unlikely as mineral extraction typically occurs within 8 miles of the shoreline. Therefore, there would be no risk of overlap with offshore structures, and their presence would have a **negligible** adverse effect on this resource. | **Offshore and Onshore:** There are no BOEM OCS sand and mineral lease areas and no identified sand resource blocks within the RWF and offshore RWEC; therefore, the Project and other reasonably foreseeable activities would have no impacts from structures or cable placement on these marine mineral resources. Similarly, because Project activities would not overlap any active dredged material disposal sites, the Project would have a **negligible** adverse impact on dredged material disposal.<br>Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall footprint, duration of construction activities, but effects would also be **negligible** adverse. | **Offshore and Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |
| Traffic: Aviation | Military air traffic use the area, and government and other private aircraft could occasionally fly over the WEA for data collection and SAR operations. Aircraft are also used for scientific and academic surveys in marine environments. | Although no future non-OSW stationary structures were identified within the offshore GAA, aircraft would continue to be used to conduct scientific research studies as well as wildlife monitoring and preconstruction surveys. SAR operations could be expected to increase with any increase in vessel traffic. However, because vessel traffic volume associated with future non-OSW is not expected to increase appreciably, neither should SAR operations. Commercial air traffic could also be expected to increase with current trends. | The effects of this IPF from the No Action Alternative would not impact marine mineral resources and dredged material disposal because aviation and air traffic are air- and land-based impacts that do not overlap with marine mineral resources and dredged material disposal uses. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource. | **Offshore and Onshore:** The effects of this IPF from the Proposed Action would not impact marine mineral resources and dredged material disposal because aviation and air traffic are air- and land-based impacts that would not impact underwater marine mineral resources and dredged material disposal. This IPF would result in a **negligible** adverse impact because there would be no effect on this resource.<br>Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall footprint, duration of construction activities, but effects would also be **negligible** adverse. | **Offshore and Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |
| Traffic: Vessels | Current vessel traffic in the region is described in Section 3.16.1. The GAA would continue to have numerous ports | Absent other information, and because total vessel transits in the area have remained relatively stable since 2010, BOEM does not | Construction and operational vessel traffic from future OSW development is expected to increase. This could create conflicts with | **Offshore and Onshore:** Construction and operational vessel traffic from the Proposed Action is expected to occur. This could create | **Offshore and Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF |

| Associated IPFs: Sub-IPFs | Ongoing Activities* | Future Non–Offshore Wind Activities Intensity/Extent | Future Offshore Wind Activities Intensity/Extent | Proposed Action and Alternatives C through F | Alternative G (Preferred Alternative) |
|---|---|---|---|---|---|
| | and extensive marine traffic related to constructed and permitted OSW COP projects, shipping, fishing, and recreation. These sources of vessel traffic may increase navigation, which could cause potential conflicts with other marine activities. | anticipate vessel traffic to greatly increase over the next 30 years. Even with increased port visits by deep draft vessels and consistent generation of new vessel traffic by proposed barge routes and dredging demolition sites, this is still a relatively small adjustment when considering the whole of New England vessel traffic | vessels undergoing marine mineral extraction and dredged disposal activities. However, because future OSW activities would take place within the RI/MA WEA and there is no marine mineral extraction or dredged material disposal areas that overlap, this impact is expected to be **negligible** adverse. | conflicts with vessels undergoing marine mineral extraction and dredged disposal activities. However, because the Proposed Action would take place within the RI-MA WEA and there is no marine mineral extraction or dredged material disposal areas that overlap, this impact is expected to be **negligible** adverse.<br>Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall footprint and duration of construction activities, but effects would also be **negligible** adverse. | would result in a **negligible** adverse impact. |
| Climate change | Climate change, influenced in part by GHG emissions, is expected to continue to contribute to a gradual warming of ocean waters and sea level rise. | No future activities were identified within the GAA other than ongoing activities. | Future OSW activities without the Proposed Action could result in construction activities that increase GHG emissions. Increased GHG emissions could contribute to climate change impacts. However, the construction of future OSW facilities would ultimately help slow the negative effects of climate change by redistributing some of the East Coast's energy generation to renewable sources. While negative impacts of climate change could affect marine mineral resources due to ocean acidification and other negative effects of climate change, future OSW activities without the Proposed Action are expected to help slow the negative impacts of climate change overall. Therefore, the effects of climate change under the No Action Alternative would be **negligible** adverse. | **Offshore and Onshore:** The Proposed Action could result in offshore and onshore construction, O&M, and decommissioning activities that increase GHG emissions. Increased GHG emissions could contribute to climate change impacts. However, O&M would help slow the negative effects of climate change by redistributing some of the East Coast's energy generation to renewable sources and reducing net GHG emissions in the area. While negative impacts of climate change could affect marine mineral resources due to ocean acidification and other negative effects of climate change, the Proposed Action is expected to help slow the negative impacts of climate change overall. Therefore, the effects of climate change under the Proposed Action by itself combined with other reasonably foreseeable projects would be **negligible** adverse.<br>Alternatives C through F would require fewer construction vessel trips and WTGs and would reduce the overall footprint and duration of construction activities, but effects would also be **negligible** adverse. | **Offshore and Onshore:** Similar impacts to the Proposed Action and Alternatives C through F. This IPF would result in a **negligible** adverse impact. |

* Includes one constructed and permitted COP project that occurs within the marine mineral GAA: SFWF.

# APPENDIX E2

## Assessment of Resources with Minor (or Less) Impact Determinations

# Contents

# Figures

# Tables

# Assessment of Resources with Minor Impact Determinations

This appendix provides an assessment of resources with minor or lower incremental impacts from implementation of the Proposed Action and other considered action alternatives. Because these sections were originally part of Chapter 3 of the Revolution Wind Farm and Revolution Wind Export Cable Project environmental impact statement (EIS), chapter and section naming and numbering were maintained for simplicity. All abbreviations and references for these sections are provided in the main EIS and Appendix B, respectively.

*This page intentionally left blank.*

## 3.4 Air Quality

### 3.4.1 Description of the Affected Environment for Air Quality

Geographic analysis area: The spatial scale for analysis of potential effects to air quality encompasses 1) the airshed within 25 miles of the estimate Project center (corresponding to the OCS Lease Area) and 2) the airshed within 15.5 miles of onshore construction areas and ports that may be used for the Project. These two areas collectively make up the air quality GAA (Figure 3.4-1) (see COP Figure 4.2.1-1). The air quality GAA encompasses the region subject to U.S. Environmental Protection Agency (EPA) review as part of an OCS permit for the Project under the Clean Air Act (CAA) and provides a reasonable buffer for the limited Project vessel and equipment emissions anticipated to occur within on-land construction areas and mustering port(s) outside of the OCS air permit area during proposed construction activities.

For the purposes of this analysis, the existing air quality conditions for each county within the GAA were evaluated. These counties comprise Providence and Washington Counties in Rhode Island, Suffolk and Kings Counties in New York, New London County in Connecticut, Gloucester County in New Jersey, Bristol and Dukes Counties in Massachusetts, Norfolk City in Virginia, and Baltimore County in Maryland.

Affected environment: The scope of the affected environment for the assessment of potential Project-related emissions and impacts to ambient air quality encompasses offshore areas and those states and counties where Project activities could occur. Project construction and O&M activities could use several regional existing port facilities as discussed in COP Section 3.3.10.1 and COP Table 3.3.10-1.

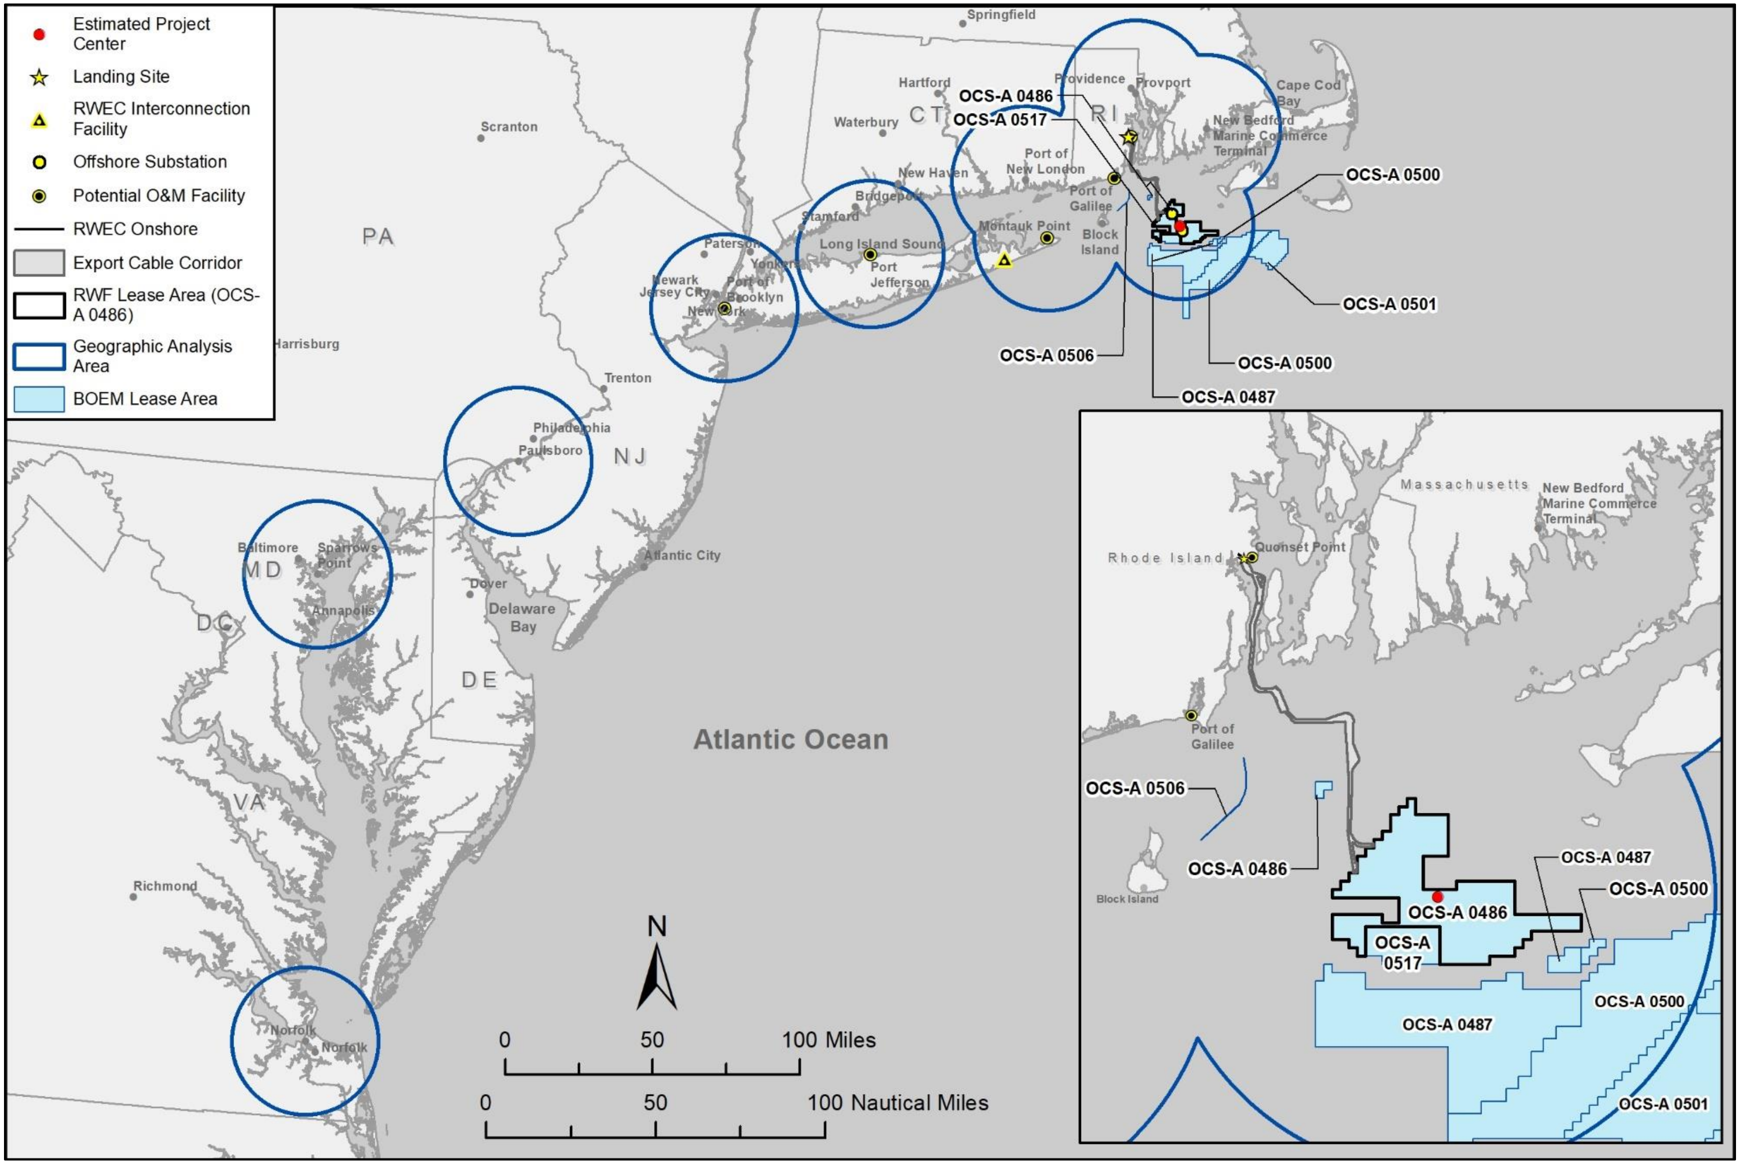

**Figure 3.4-1. Geographic analysis area for air quality.**

Air quality within a region is measured in comparison to the National Ambient Air Quality Standards (NAAQS), which are standards established by the EPA under the CAA (42 USC 7409) for criteria pollutants. The EPA has developed these standards to protect human health and welfare (primary standards) and provide public welfare protection, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings (secondary standards). The criteria pollutants for which NAAQS have been established are carbon monoxide (CO), sulfur dioxide ($SO_2$), particulate matter 10 microns or less ($PM_{10}$), particulate matter 2.5 microns or less ($PM_{2.5}$), nitrogen dioxide ($NO_2$), ozone ($O_3$), and lead. The NAAQS are summarized in Table 3.4-1.

**Table 3.4-1. National Ambient Air Quality Standards**

| Pollutant | | Primary or Secondary | Form | Averaging Time | NAAQS |
|---|---|---|---|---|---|
| CO | | Primary | Not to be exceeded more than once per year | 8 hours | 9 parts per million (ppm) |
| | | | | 1 hour | 35 ppm |
| Lead | | Primary and secondary | Not to be exceeded | Rolling 3-month average | 0.15 microgram per cubic meter (μg/m$^3$) |
| $NO_2$ | | Primary | Ninety-eighth percentile of 1-hour daily maximum concentrations, averaged over 3 years | 1 hour | 100 parts per billion (ppb) |
| | | Primary and secondary | Annual mean | 1 year | 53 ppb |
| Ozone | | Primary and secondary | Annual fourth-highest daily maximum 8-hour concentration, averaged over 3 years | 8 hours | 0.070 ppm |
| PM | $PM_{2.5}$ | Primary | Annual mean, averaged over 3 years | 1 year | 12 μg/m$^3$ |
| | | Secondary | Annual mean, averaged over 3 years | 1 year | 15 μg/m$^3$ |
| | | Primary and secondary | Ninety-eighth percentile, averaged over 3 years | 24 hours | 35 μg/m$^3$ |
| | $PM_{10}$ | $PM_{10}$ | Primary and secondary | Not to be exceeded more than once per year on average over 3 years | 150 μg/m$^3$ |
| $SO_2$ | | Primary | Ninety-ninth percentile of 1-hour daily maximum concentrations, averaged over 3 years | 1 hour | 75 ppb |
| | | Secondary | Not to be exceeded more than once per year | 3 hours | 0.5 ppm |

Source: EPA (2023).

Note: $PM_{10}$ = PM between 2.5 and 10 micrometers in diameter; $PM_{2.5}$ = PM less than 2.5 micrometers in diameter.

* Preliminary guidance from the EPA looks to reduce the annual $PM_{2.5}$ standard from 12 μg/m$^3$ to the range of 9–10 μg/m$^3$

The EPA uses design values to designate and classify nonattainment areas. A design value is a statistic that describes pollutant levels at a given location so they can be compared to the NAAQS. Nonattainment occurs if any criteria air pollutant concentration design value exceeds its NAAQS. The CAA amendments of 1990 established the nonattainment designations as marginal, moderate, and serious. If a region is designated as nonattainment for a NAAQS, the CAA requires the state to develop a state implementation plan (SIP). A SIP provides for the implementation, maintenance, and enforcement of the NAAQS, and includes emission limitation and control measures to attain and maintain the NAAQS. The CAA also prohibits federal agencies from approving any activity that does not conform to a SIP, and this prohibition applies only with respect to nonattainment or maintenance areas (i.e., areas that were previously nonattainment and for which a maintenance plan is required). Conformity to a SIP means conformity to a SIP's purpose of reducing the severity and number of violations of the NAAQS to achieve attainment of such standards. The activities for which BOEM has authority are outside of any nonattainment or maintenance area, and BOEM lacks any continuing program responsibility over activities potentially within any nonattainment area. Therefore BOEM's approval of the COP is not subject to the requirement to show conformity.

The areas of attainment for criterial pollutants within the GAA reported by the EPA (2021a) are in Table 3.4-2.

**Table 3.4-2. U.S. Environmental Protection Agency Areas of Attainment for Criteria Pollutants**

| Location | EPA Reporting |
|---|---|
| Rhode Island, including all counties | Currently in attainment for all criteria pollutants. |
| Norfolk City, Virginia | Currently in attainment for all criteria pollutants. |
| Bristol and Norfolk Counties, Massachusetts | Currently in attainment for all criteria pollutants, but Dukes County is currently in marginal nonattainment for the 2008 8-hour $O_3$ standard. |
| Suffolk and Kings Counties, New York | Currently in severe nonattainment for the 2008 8-hour $O_3$ standard, moderate nonattainment for the 2015 8-hour $O_3$ standard, and in maintenance for the 2006 24-hour $PM_{2.5}$ standard. |
| Gloucester County, New Jersey | Currently in marginal nonattainment for the 2008 8-hour $O_3$ standard, moderate nonattainment for the 2015 8-hour $O_3$ standard, and in maintenance for the 2006 24-hour $PM_{2.5}$ standard. |
| New London County, Connecticut | Currently in serious nonattainment for the 2008 8-hour $O_3$ standard and moderate nonattainment for the 2015 8-hour $O_3$ standard. |
| Baltimore County, Maryland | Currently in moderate nonattainment for the 2008 8-hour $O_3$ standard and the 2015 8-hour $O_3$ standard, and nonattainment for the 2010 $SO_2$ standard. |

Additional descriptions of air quality conditions for counties in nonattainment status are provided below.

Dukes County, Massachusetts, is an island community with a relatively low population density and little heavy industry. As is common in the northeastern region, non-road engines used for construction activities and on-road vehicle traffic are the main sources of nitrogen oxide ($NO_X$) in Dukes County (EPA 2020a). Vegetation sources and non-road engines are the primary volatile organic compound (VOC) emission sources in Dukes County. VOC and $NO_X$ are precursor pollutants to the formation of $O_3$.

Although the EPA currently classifies Dukes County as being in marginal nonattainment for the 2008 8-hour $O_3$ standard, ambient air quality monitors in Dukes County reported a steady decrease in $O_3$ levels from 2012 to 2015 (EPA 2021b). The EPA also recently (August 2018) designated Dukes County in attainment for the more stringent 2015 8-hour $O_3$ standard of 70.0 parts per billion (ppb) based on the 2014–2016 $O_3$ design value of 64.3 ppb (EPA 2021b). Recently, Dukes County reported an $O_3$ design value of 70.0 ppb for the 2016–2018 time period, 71.0 ppb for the 2017–2019 time period, and 66.0 ppb for the 2018–2020 time period (EPA 2021b).

Suffolk and Kings Counties, New York, have a high population density and Suffolk County sees the highest amount of commuter miles traveled in the New York metro area (EPA 2017). Suffolk County reported a steady decrease in $O_3$ concentration levels from 2017 to 2020 (EPA 2021b). The $O_3$ design value based on observations at the Riverhead air monitor in Suffolk County was 76.7 ppb during the 2015–2017 time period, 75.3 ppb for the 2016–2018 time period, 72.0 ppb for the 2017–2019 time period, and 70.0 ppb for the 2018– 2020 time period (EPA 2021b). There is no $O_3$ air monitor within Kings County. The nearby air monitor in Queens County reported a decrease in $O_3$ concentration levels from 2018 to 2020. The $O_3$ design value based on observations at the Queens College air monitor in Queens County was 74.0 during the 2015–2017 time period, 74.0 ppb for the 2016–2018 time period, 74.0 ppb for the 2017–2019 time period, and 70.0 ppb for the 2018–2020 time period (EPA 2021b). Thus, the EPA currently classifies Kings and Suffolk Counties as being in severe nonattainment for 8-hour $O_3$ according to the 2008 standard and in moderate nonattainment for the 2015 standard. Both counties are also in maintenance for the 2006 24-hour $PM_{2.5}$ standard. The EPA reports that on-road vehicles are the primary source of $NO_X$ emissions emitted within Kings and Suffolk Counties; non-road engines are the second-largest source. Vegetation sources, solvent use in industry, off-highway engines, and on-road vehicles provide the most VOC emissions emitted within Kings and Suffolk Counties (EPA 2020a).

Gloucester County, New Jersey, has a much lower population density than Suffolk and Kings Counties, New York. Air quality within Gloucester County is affected by nearby Philadelphia. $NO_X$ emissions in Gloucester County are primarily from on-road vehicles, with fuel combustion for industrial purposes, electric generation, and other needs being the second-largest source. Storage and transport, vegetation, and solvent use are the primary sources of VOC emissions in Gloucester County (EPA 2020a). Although the EPA currently classifies Gloucester County as being in marginal nonattainment for the 2008 8-hour $O_3$ standard and moderate nonattainment for the 2015 8-hour $O_3$ standard, the ambient air quality monitor in Gloucester County reported a steady decrease in $O_3$ levels from 2018 to 2020 (EPA 2021b). Gloucester County reported an $O_3$ design value of 74.0 ppb for the 2015–2017 and 2016–2018 time periods, 72.0 ppb for the 2017–2019 time period, and 69.0 ppb for the 2018–2020 time period (EPA 2021b).

New London County, Connecticut, is a rural county with a low population density and small industrial bases. Neighboring metro areas outside this county heavily affect the air quality of the county in addition to regional sources. For this reason, changes to pollutant emissions by sources within the county have little impact on the overall air quality trends. $NO_X$ emissions in New London County are primarily from on-road vehicles, with fuel combustion for industrial purposes, electric generation, and other needs being the second-largest source. Vegetation sources and solvent use are the primary sources of VOC emissions (EPA 2020a). Although the EPA currently classifies the county as being in serious nonattainment for the 2008 8-hour $O_3$ standard and moderate nonattainment for the 2015 8-hour $O_3$ standard, the ambient air quality monitor in the county reported a small decrease in $O_3$ levels from 2018 to 2020 (EPA 2021b). New London County reported an $O_3$ design value of 76.0 ppb for the 2015–2017 time period, 75.0 ppb for the 2016–2018 and the 2017–2019 time periods, and 73.0 ppb for the 2018–2020 time period (EPA 2021b).

Baltimore County, Maryland, has a population density three times greater than New London County, Connecticut. Although the EPA currently classifies Baltimore County as being in moderate nonattainment for both the 2008 and 2015 8-hour $O_3$ standards, ambient air quality monitors in Baltimore County reported a steady decrease in $O_3$ levels from 2018 to 2020 (EPA 2021b). The $O_3$ design value based on observations at the Essex air monitor in Baltimore County was 73.0 ppb for the 2015–2017 and 2016–2018 time periods, 72.0 ppb for the 2017–2019 time period, and 69.0 ppb for the 2018–2020 time period (EPA 2021b). In Baltimore County, $NO_X$ emissions are primarily from on-road vehicles, with fuel combustion for industrial purposes, electric generation, and other needs being the second-largest source. Vegetation, solvent use, and on-road vehicles are the main sources of VOC emissions (EPA 2020a). The EPA has also classified Baltimore County as being in nonattainment for the 2010 $SO_2$ standard, although the $SO_2$ air quality monitor in Baltimore County has reported a steady decline in $SO_2$ concentration levels since 2016 (EPA 2021b). Baltimore County reported an $SO_2$ design value of 13.0 ppb for the 2015–2017 time period, 11.0 ppb for the 2016–2018 time period, 10.0 ppb for the 2017–2019 time period, and 9.0 ppb for the 2018–2020 time period (EPA 2021b). The main source of $SO_2$ emissions in Baltimore County comes from fuel combustion for electric generation (EPA 2020a).

The Ozone Transport Region (OTR) was established by operation of law under CAA Section 184 and comprises the states of Connecticut, Delaware, Maine, Massachusetts, Maryland, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont; the District of Columbia; and the portion of Virginia that is within the Consolidated Metropolitan Statistical Areas that includes the District of Columbia. Congress established the OTR in the 1990 CAA amendments based on the recognition that the transport of ozone and ozone precursors throughout the region may render the states' attainment strategies interdependent. States within the OTR may have similar permitting requirements as ozone nonattainment areas.

Table 3.4-3 presents the total emission inventory in tons per year (tpy) for select regulated pollutants (i.e., CO, $NO_X$, $PM_{10}$, $PM_{2.5}$, $SO_2$, and VOC) in nonattainment counties in 2017.

**Table 3.4-3. Nonattainment Counties, 2017 Emission Inventory for Regulated Pollutant (tpy)**

| County, State | CO | $NO_X$ | $PM_{10}$ | $PM_{2.5}$ | $SO_2$ | VOC |
|---|---|---|---|---|---|---|
| New London County, Connecticut | 25,671.25 | 5,300.74 | 2,882.84 | 1,072.31 | 289.57 | 15,606.98 |
| Dukes County, Massachusetts | 6,395.82 | 989.64 | 407.96 | 135.99 | 13.07 | 2,740.63 |
| Baltimore County, Maryland | 71,702.20 | 10,661.44 | 12,184.54 | 3,207.24 | 1,041.34 | 16,919.12 |
| Gloucester County, New Jersey | 30,399.73 | 6,260.63 | 2,161.41 | 1,311.48 | 599.94 | 10,507.34 |

| County, State | CO | $NO_X$ | $PM_{10}$ | $PM_{2.5}$ | $SO_2$ | VOC |
|---|---|---|---|---|---|---|
| Kings County, New York | 59,473.56 | 13,571.74 | 4,959.06 | 2,559.52 | 477.53 | 17,660.21 |
| Suffolk County, New York | 146,719.86 | 20,336.81 | 9,682.55 | 3,889.70 | 1,197.73 | 32,676.35 |

Source: EPA (2020a).

The CAA provides special air quality protection to national parks larger than 6,000 acres and national wilderness areas larger than 5,000 acres that were in existence before August 1977 (National Park Service 2020). These areas are referred to as Class I areas and are managed by the U.S. Forest Service (USFS), National Park Service (NPS), and U.S. Fish and Wildlife Service (USFWS). Designation as a Class I area allows only very small increments of new pollution above already existing air pollution levels. One of the purposes of the Prevention of Significant Deterioration permitting program under the CAA, is to preserve, protect, and enhance the air quality in national parks, national wilderness areas, national monuments, national seashores, and other areas of special national or regional natural, recreational, scenic, or historic value. Air quality related values (AQRVs) are used to determine whether these resources may be adversely affected by a change in air quality. Federal land managers AQRVs include visibility, vegetation, water quality, soils, and impacts to fish and wildlife. The potential harm from air pollution to these resources depends on quantity of emission, the type of air emission exposure, and the sensitivity of the resources. Current visibility conditions and trends in Class I areas are established via the IMPROVE (Interagency Monitoring of Protected Visual Environments) program. The nearest Class I areas to the Proposed Action are Lye Brook Wilderness, located approximately 155 miles northwest of the Lease Area, and Brigantine Wilderness, located approximately 190 miles southwest of the Lease Area. The Lye Brook Wilderness IMPROVE monitor is located on the ski slopes of Mount Snow approximately 9.5 miles southeast of the Lye Brook Wilderness Area boundary. The Brigantine Wilderness is made up of three separate areas; all three are part of the Edwin B. Forsythe National Wildlife Refuge. The Brigantine Wilderness IMPROVE monitor is located at the Edwin B. Forsythe National Wildlife Refuge Visitor Center, approximately 4 miles west and 4 miles south-southwest of the two closest Brigantine Wilderness Area boundaries. Visibility at both the Lye Brook Wilderness and Brigantine Wilderness Class I areas has been steadily improving since 2010 (Federal Land Manager Environmental Database 2021). No visibility or deposition modeling was conducted as part of this EIS analysis because both Lye Brook Wilderness and Brigantine Wilderness Class I areas are located more than 155 miles away from the Lease Area. If further visibility modeling is required, it will be conducted during the OCS permitting process. As part of the EPA's OCS air permit, the Project will be evaluated for compliance with NAAQS and PSD increments for operating emissions and significant impact level, and an AQRV analysis will be conducted at the Lye Brook Wilderness Area for construction emissions.

*Climate Change*: Climate change is a global issue that results from the increase in greenhouse gases (GHGs) in the atmosphere. An analysis of regional climate impacts prepared by the Fourth National Climate Assessment (U.S. Global Change Research Program 2018) concludes that the rate of warming in the Northeast has markedly accelerated over the past few decades, with seasonal differences in temperature decreasing in recent years as winters have warmed three times faster than summers. Higher temperatures from the increase of GHGs in the atmosphere increase the number of heat events and extreme rain events that cause coastal flooding. The higher temperatures also extend the duration of the pollen season. Analysis of past records and future projections indicates an overall increase in regional temperatures, including near the Lease Area. The most recently available data on GHG emissions in the

United States indicate that annual GHG emissions in 2019 were an estimated 6,558 million metric tons of carbon dioxide equivalents ($CO_2e$) (EPA 2021c).

Sulfur hexafluoride ($SF_6$) is often used in electrical switchgears because of its unique properties. However, $SF_6$ is also the most potent GHG known to date. Fortunately, it is technically feasible to use $SF_6$-free switchgears for medium voltage switchgear up to 36 kV. Recent independent evaluations show that $SF_6$-free switchgear is not only technically equivalent, but also more cost competitive over the full service life (Eaton 2021).

The Project would be designed in accordance with the International Electrotechnical Commission 61400-1 and 61400-3 standards. These standards require designs to withstand forces based on site-specific conditions for a 50-year return interval (2% chance occurrence in a single year) for the WTGs, which corresponds to a Category 3 hurricane in this area (International Electrotechnical Commission 2019a). This means that the WTGs are designed not merely for average conditions but for the higher end event that is reasonably likely to occur. The newly revised International Electrotechnical Commission 61400-3 standard now also recommends a robustness load case for extreme metocean conditions, where the WTG support structures are checked for a 500-year event (0.2% chance occurrence in a single year), which corresponds to wind gusts at the strength of a Category 5 hurricane, to ensure that the appropriate level of safety is maintained in case of a less likely event (International Electrotechnical Commission 2019b). The Project would be constructed using a certified verification agent to ensure that all design specifications are met. The Project would also be designed in alignment with the findings of the *NYSERDA: Offshore Wind Climate Adaptation and Resilience Study* (New York State Energy Research and Development Authority [NYSERDA] 2021). It is possible that severe weather could cause blades to fail, but because of the construction design, it is highly unlikely that the towers would topple.

### 3.4.2 Environmental Consequences

#### 3.4.2.1 Relevant Design Parameters, Impact-Producing Factors, and Potential Variances in Impacts

The Project design parameters that would influence the magnitude of impacts on air quality are listed in Table 3.4-4.

**Table 3.4-4. Project Design Parameters**

| Design Parameter |
|---|
| Air emission ratings of construction equipment engines |
| Port selection and location of construction laydown areas |
| Choice of cable-laying locations and pathways |
| Choice of marine traffic routes to and from the Lease Area |
| Number of offshore substations |
| Soil characteristics at excavation sites |
| Emission control strategy for fugitive emissions due to excavation and hauling operations |

Variability of the Project design as a result of the PDE includes the number of WTGs and their spacing within the Lease Area, spatial coverage of the overall Lease Area, and the construction schedule. A reduction (or increase) in the number of WTGs installed and their associated IACs would likely have an associated reduction (or increase) in associated vessel and equipment use and their generated air emissions. Additionally, variations in the planned cable layout and landfall locations would impact the magnitude and spatial extent of emissions. Appendix D provides additional information about the PDE.

See Appendix E1 for a summary of IPFs analyzed for air quality across all action alternatives. IPFs that are either not applicable to the resource or determined by BOEM to have a negligible effect are excluded from Chapter 3 and provided in Table E1-1 in Appendix E1. Offshore and onshore IPFs are addressed separately in the analysis if appropriate for the resource; not all IPFs have both an offshore and onshore component. Where feasible, calculations for specific alternative impacts are provided in Appendix E4 to facilitate reader comparison across alternatives.

Table 3.4-5 discloses IPF findings carried forward for analysis in this section. Each alternative analysis discussion consists of the construction and installation phase, the O&M phase, the decommissioning phase, and the cumulative analysis. If these analyses are not substantially different, then they are presented as one discussion.

A detailed analysis of the Proposed Action follows the table. Detailed analysis of other considered action alternatives is also provided below the table if analysis indicates that the alternative(s) would result in substantially different impacts than the Proposed Action.

The conclusion section for each alternative analysis provides additional rationale for this impact determination. The overall impact of any alternative would be **moderate** adverse because the overall effects would be notable, but the resource would recover completely from adverse impacts without mitigation or remedial action.

<table>
<tr><th>Impact-Producing Factor</th><th>Alternative A<br>(No Action Alternative)</th><th>Alternative B<br>(Proposed Action)<br>Up to 100 WTGs*</th><th>Alternative C<br>(Habitat Alternative)<br>64 or 65 WTGs</th><th>Alternative D<br>(Transit Alternative)<br>78 to 93 WTGs</th><th>Alternative E<br>(Viewshed Alternative)<br>64 or 81 WTGs</th><th>Alternative F<br>(Higher Capacity Turbine Alternative)<br>56 WTGs</th><th>Alternative G<br>(Preferred Alternative)<br>65 WTGs</th></tr>
<tr><td rowspan="2">Air emissions and climate change</td><td>Offshore: During construction, impacts from future wind development activities on air quality would be temporary and minor to moderate adverse, depending on the extent and duration of emissions. Primary emission sources would include increased vessel and air traffic, combustion emissions from construction equipment, and fugitive emissions.<br><br>Future offshore wind projects could also beneficially contribute to a broader combination of actions to reduce future impacts from climate change over the long term.</td><td>Offshore: Project construction would have a limited duration, and most emissions would occur offshore. The only air emissions anticipated during O&M would result from crew and maintenance vessels and helicopters. Therefore, impacts on air quality near populated areas would be temporary minor adverse. Project O&M would also generate long-term minor beneficial impacts by providing energy to the region from a renewable resource and due to avoided health events.<br><br>The overall cumulative impacts associated with the Proposed Action when combined with other past, present, and reasonably foreseeable activities would be moderate adverse, although regional air quality could be improved over the Project life cycle when compared to the No Action Alternative.</td><td colspan="4">Offshore: When compared to the maximum case for the Proposed Action, construction under Alternatives C through F could result in a decrease in Project-related emissions due to less trenching and/or vessel traffic to install a reduced number of WTGs and their associated IACs. In such cases, emissions from construction and installation would be less than the Proposed Action but still temporary minor adverse.<br><br>Alternatives C through F could also result in reduced O&M emissions because fewer WTGs installed, when compared to the maximum case under the Proposed Action, would mean potentially reduced inspection time, fewer turbines needing regular maintenance, etc. Alternatives C through F would avoid similar amounts of emissions as the minimum and maximum avoided emission values for the Proposed Action presented in Table 3.4-13. During O&M, Alternatives C through F would also result in long-term minor beneficial impacts on regional air quality by substituting some existing fossil fuel sources with a renewable source, which would contribute to a long-term net decrease in emissions in the region. Therefore, overall impacts on air quality under Alternatives C through F would likely be minor adverse and long term minor beneficial.<br><br>Alternatives C through F would result in impacts on air quality at quantities and durations similar to, or slightly reduced from, the Proposed Action. Although regional air quality could be improved when compared to the No Action Alternative, it would be too remote or speculative to conclude what that change would be. Given the marginal reduction, however, the cumulative impacts of Alternatives C through F on air quality when combined with past, present, and reasonably foreseeable activities would remain moderate adverse.</td><td>Offshore: Alternative G would reduce the number of allowable WTGs and their associated IACs, which would likely have a corresponding reduction in associated vessel and equipment use and air emissions compared to the Proposed Action. BOEM expects the impacts from this alternative would be similar to the Proposed Action: minor adverse due to air emissions from construction activities.<br><br>Alternative G could also have fewer O&M emissions because there would be fewer WTGs to inspect and maintain compared to the Proposed Action. Alternative G would also contribute to long-term minor beneficial impacts by substituting some fossil fuel sources of electricity generation with a lower emitting renewable source and therefore would result in a net reduction in cumulative air emissions in the region.<br><br>In the context of other reasonably foreseeable environmental trends and planned actions, BOEM expects that the alternative's impacts would be similar to the Proposed Action (with individual IPFs leading to impacts that would be short term minor adverse and long term minor beneficial). The overall cumulative impacts of Alternative G on air quality when combined with past, present, and reasonably foreseeable activities would therefore be the same as the Proposed Action: moderate adverse, with potential regional improvements to air quality when compared to the No Action Alternative.</td></tr>
<tr><td>Onshore: Ongoing activities and reasonably foreseeable activities other than offshore wind would result in moderate adverse impacts on air quality, primarily driven by recent market and permitting trends indicating future electric generating units would most likely include natural gas–fired and oil-fired dual fuel facilities, a mix of natural gas, and dual fuel natural gas/oil.</td><td>Onshore: Air emissions generated by construction and O&M of the onshore facilities could have temporary negligible to minor adverse impacts on air quality.<br><br>When combined with other onshore sources of air emissions, cumulative impacts on air quality from onshore Project activities would be long term minor adverse.</td><td colspan="4">Onshore: Alternatives C through F would not impact onshore activities; therefore, construction and O&M impacts would be the same as those described for the Proposed Action: temporary, negligible to minor adverse. Cumulative impacts would also be the same as those described for the Proposed Action: long term minor adverse.</td><td>Onshore: Alternative G would not impact onshore activities. The impacts to air quality from construction and O&M of Alternative G would be the same as the Proposed Action: temporary, negligible to minor adverse. Likewise, the cumulative impacts would be the same as the cumulative impacts from the Proposed Action: long term minor adverse.</td></tr>
</table>

* If the Proposed Action were to select an 11- to 12–MW turbine, then the total number of WTGs installed and impacts from associated air emissions would be similar or the same as those under Alternatives C through F.

### 3.4.2.2 Alternative A: Impacts of the No Action Alternative on Air Quality

#### 3.4.2.2.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for air quality (see Section 3.4.1) would continue to follow current regional trends and respond to IPFs introduced by other ongoing activities and by permitted and constructed offshore wind COP projects within the air quality GAA. These IPFs are described and analyzed in Appendix E1.

#### 3.4.2.2.2 Cumulative Impacts

This section discloses potential cumulative air quality impacts associated with future offshore wind development (without the Proposed Action). The cumulative impact analysis for the No Action Alternative for planned non-offshore wind activities, as well as activities associated with constructed or approved offshore wind projects (without the Proposed Action), is provided in Appendix E1.

<u>Air emissions and climate change</u>: Under the No Action Alternative, assuming no other future offshore wind projects are developed, electric generation needs would continue to be met by fossil fuel–generating technologies, resulting in more air emissions than what would be expected should future offshore wind development occur. Specific impacts would depend on the type of fossil fuel used (natural gas, oil, coal), the technology and pollution control systems chosen, and the site-specific issues associated with individual electric generation facilities. However, the continued use of existing fossil fuel–combusting electric generation sources would result in annual emissions that could have been avoided by using non–fossil fuel energy sources.

Using the EPA's Avoided Emissions and geneRation Tool (AVERT) version 4.1, avoided $CO_2$ emissions are calculated for the operational life of the Project with a capacity factor of 45% (AVERT offshore wind default) for the New England region based on the EPA's 2019 regional data file. More recent data are available, but because of the temporary declines in electricity demands, particularly from March through May 2020 likely caused by the COVID-19 pandemic, the EPA recommends using the 2019 regional data file when assessing annual, near-term future avoided emissions. Table 3.4-18 contains the associated annual $CO_2e$ emissions (and avoided $CO_2$ emissions) for each alternative and the No Action Alternative. The No Action Alternative emissions were assumed equivalent to the emissions that would be avoided by the operation of the Proposed Action. The No Action Alternative (Alternative A) would result in no emissions during construction and O&M because the Project would not be built, but the No Action Alternative would also offer no avoided emissions, resulting in higher GHG emissions over the Project duration by not displacing traditional power generation via offshore wind. The missing avoided GHG emissions are equivalent to 268,076 gasoline-powered passenger vehicles driven each year. These figures are relative to the existing grid configuration, but the actual annual quantity of avoided emissions attributable to this proposed facility is expected to diminish over time if the electric grid becomes greener due to the addition of other renewable energy facilities and retirement of high-emitting generators.

Assuming the development of other future wind development and other renewable energy sources, these sources would decrease emissions over the long term, likely reduce the need for traditional fossil fuel power generation in the region, and could result in improved air quality when compared to expected air quality without other future wind development and renewable energy sources. Adjacent states have also proposed emission-reduction targets and renewable goals that overlap the operations of the Project and that are aimed at reducing air emissions and shifting energy sources from traditional fossil fuel generation to cleaner sources of energy. These plans could further reduce, but would not eliminate, air emissions.

During construction, impacts from future wind development activities on air quality under the No Action Alternative would be temporary **minor** to **moderate** adverse, depending on the extent and duration of emissions. Primary emission sources would include increased vessel and air traffic, combustion emissions from construction equipment, and fugitive emissions. Engine idling time would be limited in the Lease Area, as recommended by BOEM. Furthermore, best available control technology or lowest achievable emission rate requirements for vessels operating as OCS sources may be as stringent as Tier 4 engine standards (the EPA's strictest emission requirements for diesel engines) and would be determined by the EPA's OCS air permit.

Based on assumed construction schedules, offshore wind development would occur with overlapping construction schedules between 2022 and 2030. As shown in Table 3.4-6, construction of these projects in the GAA with sufficient details to estimate emissions would generate an estimated 124,277 tons of $NO_X$, 2,684 tons of $SO_2$, 5,795 tons of $PM_{10}$, and 7,709,706 metric tons of $CO_2e$ over the 8-year construction period. For comparison purposes, according to the EPA's 2017 National Emissions Inventory, Suffolk County reported 8,122 tons of $NO_X$, 124 tons of $SO_2$, and 872 tons of $PM_{10}$ from highway vehicles; 6,566 tons of $NO_X$, 34 tons of $SO_2$, and 537 tons of $PM_{10}$ from off-highway vehicles; and 860 tons of $NO_X$, 421 tons of $SO_2$, and 146 tons of $PM_{10}$ from electrical utilities' combustion of fuel (EPA 2020a). Similarly, future offshore wind project GHG emissions during construction would be negligible (7,709,706 metric tons of $CO_2e$) as compared to aggregate global emissions, and these projects could beneficially contribute to a broader combination of actions to reduce future impacts from climate change over the long term. An analysis by Barthelmie and Pryor (2021) calculated that, depending on global trends in GHG emissions and the amount of wind energy expansion, development of wind energy could reduce predicted increases in global surface temperature by 0.3 to 0.8 degrees Celsius (°C) (0.5–1.4 degrees Fahrenheit [°F]) by 2100.

As shown in Table 3.4-7, the O&M of future offshore wind projects in the GAA would have a proportionally small contribution of long-term and intermittent emissions, including 2,940 tons of $NO_X$, 44 tons of $SO_2$, 110 tons of $PM_{10}$, and 700,114 metric tons of $CO_2e$.

#### 3.4.2.2.3 Conclusions

Under the No Action Alternative, BOEM would not approve the COP; Project construction and installation, O&M, and decommissioning would not occur; and potential impacts on air quality associated with the Project would not occur. However, ongoing and future activities would have continuing temporary to long-term impacts on air quality, primarily through construction-related air emissions.

BOEM anticipates that the impacts of ongoing activities, such as air emissions and GHGs, would be **moderate** adverse. In addition to ongoing activities, reasonably foreseeable activities other than offshore wind could also contribute to impacts on air quality. Reasonably foreseeable activities, other than offshore wind, that will increase air emissions and GHGs include construction and operation of new energy generation facilities to meet future power demands as transportation and heating become increasingly electrified. Although states are developing onshore renewable energy facilities (through their state energy plans) to the extent practicable to help meet future demand, these state plans also depend on the development of offshore wind. Therefore, under the No Action Alternative, to the extent that offshore wind is not developed, there would be a shortfall from planned renewable power generation, and nonrenewable sources would likely be needed to meet future demand. These facilities could include new natural gas–fired power plants or coal-fired, oil-fired, or clean coal–fired plants. Areas of nonattainment would be faced with potentially increased emissions or struggle to meet air quality goals. BOEM anticipates that the impacts of reasonably foreseeable activities other than offshore wind would be **moderate** adverse. BOEM expects the combination of ongoing activities and reasonably foreseeable activities other than offshore wind to result in **moderate** adverse impacts on air quality, primarily driven by recent market and permitting trends indicating future electric generating units would most likely include natural gas–fired and oil-fired dual fuel facilities, a mix of natural gas, and dual fuel natural gas/oil.

Considering all the IPFs together, BOEM anticipates that the impacts associated with future offshore wind activities in the GAA combined with ongoing activities, reasonably foreseeable environmental trends, and reasonably foreseeable activities other than offshore wind would be **minor** to **moderate** adverse. Emissions generated from construction and decommissioning of the offshore wind projects would be the primary source of impacts to air quality. Other future offshore wind projects could also lead to reduced emissions from fossil fuel–combusting power generation facilities, resulting in **minor** to **moderate** beneficial impacts on air quality.

### 3.4.2.3 Alternative B: Impacts of the Proposed Action on Air Quality

In their *Air Emissions Calculations and Methodology* technical report, Tech Environmental (2023) conservatively assumed that construction of the Project would only take 1 year. For estimating potential transit emissions, 11 regional ports that could be used during construction and O&M were considered (Table 3.4-8).

**Table 3.4-8. Regional Ports Considered**

| Port Name | Location |
|---|---|
| Port of Providence | Providence County, Rhode Island |
| Port of Davisville at Quonset Point | Washington County, Rhode Island |
| Port of Montauk | Suffolk County, New York |
| Port Jefferson | Suffolk County, New York |
| Port of Brooklyn | Kings County, New York |
| Port of New London | New London County, Connecticut |
| Paulsboro Marine Terminal | Gloucester County, New Jersey |
| New Bedford Marine Commerce Terminal | Bristol County, Massachusetts |
| Cashman Shipyard in Quincy | Norfolk County, Massachusetts |
| Port of Norfolk | Norfolk City, Virginia |
| Sparrow's Point | Baltimore County, Maryland |

All ports except New York's Port of Montauk, Port Jefferson, and Port of Brooklyn were used for estimating construction emissions. The three ports in New York and the Port of Davisville at Quonset Point in Rhode Island were used for estimating O&M emissions.

It was conservatively assumed that when there were multiple port options for a particular Project phase involving regular transit, the port used for the emission calculations was the one with the longest transit distance. In the cases where multiple ports were listed as potential ports for vessel activities, the emissions were conservatively allocated to all potential ports. This approach provides a very conservative estimate of potential emissions for each state.

$O_3$ emissions are not included in the air quality impact analyses presented herein. $O_3$ emissions cannot be easily quantified since $O_3$ formation is a byproduct of chemical reactions between VOC and $NO_X$ caused by heat and sunlight and thus emissions of $O_3$ depend on local weather conditions.

#### 3.4.2.3.1 Construction and Installation

##### Offshore Activities and Facilities

Air emissions and climate change: Table 3.4-9 presents a summary of the Project's estimated offshore construction emissions emitted during a maximum-case scenario in which all construction activities would occur in a single year. Construction emissions occurring within 15.5 miles of on-land construction areas and port locations are compared to the emission inventories of the impacted counties.

Over the approximate 1-year construction period, Project air emissions from vessels, helicopters, generators, and fuel-burning equipment could have temporary, direct impacts on air quality. Estimated emissions for most pollutants occurring within 15.5 miles of on-land construction areas and port locations would represent a 16.0% or less temporary increase in air pollutants for counties within the GAA. $NO_X$ construction emissions are more substantial in comparison to the counties' $NO_X$ emissions (in the range of 2%–45%). However, these emissions would be temporary and could be reduced by implementing proposed EPMs (see Table F-1 in Appendix F). Furthermore, this is a conservative analysis of the impact of the construction emissions occurring within 15.5 miles of on-land construction areas and port locations because it assumes all of the emissions would directly affect the nearest county's air. Emissions occurring outside the OCS permit area within 15.5 miles of on-land construction areas and port locations would primarily result from transit vessels used to transport equipment and material. Vessel engines are required to meet certain emission standards and must use low-sulfur diesel fuel. Realistically, vessel transit emissions would be spread out over the transport route. Depending on wind conditions at the time of emissions, it is likely that not all emissions generated miles offshore would reach land. Therefore, Project construction activities would have a temporary **minor** adverse impact on New London, Gloucester, Baltimore, Providence, Washington, Bristol, and Norfolk City Counties' air quality.

Construction emissions occurring offshore in the OCS permit area are not compared to county emission inventories because only a portion of the generated construction emissions would actually reach nearby counties and would depend on wind conditions at the time the emissions are generated. The OCS air permitting process will require air dispersion modeling of these emissions to demonstrate compliance with the NAAQS. If the Project cannot demonstrate compliance, the permit would not be issued, and the Project would not proceed.

The emission totals presented in the analysis represent a worst-case construction scenario in which all construction activities would occur in a single year. Project construction would also have a limited duration, and most emissions would occur offshore. The emissions quantified in Table 3.4-9 would not be emitted entirely at a single point or port and would not continuously affect nearby populated areas. Therefore, impacts on air quality near populated areas would be temporary **minor** adverse.

**Table 3.4-9. Summary of Geographic Analysis Area Offshore Construction Emissions (tpy)**

Notes:

RWF-Connecticut = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from the Port of New London.

RWF-New Jersey = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from the Paulsboro Marine Terminal.

RWF-Rhode Island = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from the Port of Providence and the Port of Davisville at Quonset Point.

RWEC-Rhode Island = the portion of RWEC offshore segment construction emissions that would occur outside the OCS permit area and within 15.5 miles of shore.

RWF-Maryland = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from Sparrow's Point.

RWF-Massachusetts = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from the New Bedford Marine Commerce Terminal and during transit to and from European ports.

RWEC-Massachusetts = the portion of RWEC offshore segment construction emissions that would occur outside the OCS permit area and within 15.5 miles of shore.

RWF-Virginia = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from the Port of Norfolk and during transit to Sparrow's Point.

RWEC-OCS = the portion of RWEC offshore segment construction emissions that would occur within the OCS permit area.

### Onshore Activities and Facilities

Air emissions and climate change: Table 3.4-10 presents the estimated onshore construction emissions for the Project. The onshore facilities, inclusive of the landfall work area, onshore transmission cable, OnSS, and ICF (including associated interconnection circuits and Project easement), would be constructed in Davisville, Washington County, Rhode Island, which is in attainment for all pollutants.

**Table 3.4-10. Summary of Emissions from Onshore Facilities Construction (tpy)**

| Source | CO | $NO_X$ | $PM_{10}$ | $PM_{2.5}$ | $SO_2$ | VOC | $CO_2e$ |
|---|---|---|---|---|---|---|---|
| OnSS and ICF | 367.5 | 382.0 | 14.6 | 13.8 | 1.3 | 26.8 | 164,525 |

Source: Tech Environmental (2023).

Construction of the onshore facilities is estimated to take 18 months, but the air technical report analysis conducted by Tech Environmental (2023) presumes that construction could occur as quickly as 1 year. Construction of the onshore facilities would involve emissions from on-road and non-road equipment, which could have temporary, direct impacts on air quality. The Port of Davisville at Quonset Point would be used for construction support activities. The estimated onshore facilities construction emissions for regulated pollutants were compared to county emission inventories for the counties within 15.5 miles of the Port of Davisville at Quonset Point (the GAA). The Proposed Action onshore facility construction $NO_X$ emissions would be approximately 5.5% of Providence County, Rhode Island's annual $NO_X$ emissions, 16.9% of Washington County, Rhode Island's annual $NO_X$ emissions, and 20.3% of Kent County, Rhode Island's annual $NO_X$ emissions. Most emissions of regulated pollutants were between 0.29% and 2.94% of Kent, Providence, or Washington Counties' annual emissions. Air emissions generated by constructing the onshore facilities could have temporary **minor** adverse impacts on air quality.

#### 3.4.2.3.2 Operations and Maintenance and Decommissioning

### Offshore Activities and Facilities

Air emissions and climate change: Emissions from the Project O&M would be much lower than those produced during construction because there would be no direct emissions associated with wind turbine operation. The only air emissions anticipated during O&M would result from crew and maintenance vessels and helicopters. Planned maintenance activities include annual turbine service and safety surveys, annual oil and lubricant changes, annual inspections of turbines and foundations, seafloor and submarine surveys, biannual electrical inspections, regular electrical component servicing, annual scheduled maintenance, and all major and minor corrective maintenance. Table 3.4-11 summarizes the Project O&M emissions estimated for the air quality GAA. Project O&M emissions occurring within 15.5 miles of on-land construction areas and port locations are compared to the emission inventories of the impacted counties. These O&M emissions occurring within 15.5 miles of on-land construction areas and port locations would increase the annual emissions of each pollutant by 1.5% or less for all counties within the GAA.

Project O&M emissions occurring offshore in the OCS permit area are not compared to county emission inventories because only a portion of these emissions would actually reach nearby counties, depending on wind conditions at the time of emission. The OCS air permitting process will require air dispersion modeling of these emissions to demonstrate compliance with the NAAQS. Therefore, Project O&M activities would have a **minor** adverse impact on the air quality in the counties in the GAA.

Project O&M would also generate long-term **minor** beneficial impacts by providing energy to the region from a renewable resource. Currently, the region in which this wind farm would serve obtains between 40% and 51% of its power through the combustion of natural gas (U.S. Energy Information Administration 2021). By replacing a portion of the air pollutant emissions generated by fossil fuel–fired power plants, significant reductions in air pollutants emissions can be achieved. A recent study of current wind projects found that there is a net reduction in emissions within 6 months of the commencement of operations (Inderscience Publishers 2014). Furthermore, as transportation and heating become increasingly electrified, the demand for electrical power will grow. Without offshore wind, states would not be able to meet their emission targets and meet this increasing demand.

**Table 3.4-11. Summary of Offshore Operations and Maintenance Emissions (tpy)**

| Source | CO | $NO_X$ | $PM_{10}$ | $PM_{2.5}$ | $SO_2$ | VOC | $CO_2e$ |
|---|---|---|---|---|---|---|---|
| **Operations and Maintenance Emissions within 15.5 Miles of Potential Project On-Land Areas and Port Locations** | | | | | | | |
| RWF-New York | 51.2 | 205.3 | 6.9 | 6.7 | 0.1 | 3.0 | 14,506 |
| Percentage of Kings County, New York, emission inventory | 0.09% | 1.51% | 0.14% | 0.26% | 0.02% | 0.02% | 0.28% |
| Percentage of Suffolk County, New York, emission inventory | 0.03% | 1.01% | 0.07% | 0.17% | 0.01% | 0.01% | 0.14% |

Source: Tech Environmental (2023).

Notes:

RWF-New York = the portion of RWF O&M emissions that would occur outside the OCS permit area and within 15.5 miles from shore during transit to and from the Port of Montauk, Port Jefferson, and the Port of Brooklyn.

RWF-Rhode Island = the portion of RWF O&M emissions that would occur beyond the OCS permit area and within 15.5 miles from shore during transit to and from the Port of Providence and the Port of Davisville at Quonset Point.

In the case of decommissioning, emissions would result largely from the operation of decommissioning equipment and vessels or aircraft. Associated air emissions would occur 35 years in the future when air quality conditions, emissions technology, and regulations would be different; therefore, estimating decommissioning emission impacts now is speculative. Because portions of the Project would be decommissioned in place, fewer decommissioning activities and less equipment would be required; therefore emissions from decommissioning activities would be less than those from construction activities. The decommissioning activities would be subject to a future OCS air permit, or similar, application. There would be no further air emissions from RWF once decommissioning is complete.

The use of wind to generate electricity reduces the need for electricity generation from new traditional fossil fuel–powered plants in New England that produce GHG emissions. BOEM obtained avoided emissions from EPA's AVERT Excel Edition, Version 4.1 for the New England region based on EPA's 2019 regional data file. Regional data for 2020 is available, but due to the temporary declines in electricity demands, particularly from March through May 2020 likely caused by the pandemic, the EPA recommends using the 2019 regional data file when assessing annual, near-term future avoided emissions. The EPA's AVERT is not a long-term projection tool. It is not intended to analyze avoided emissions more than 5 years from baseline. To provide a very rough estimate of the long-term avoided emissions of the Project, the maximum and minimum annual avoided emissions estimated by AVERT were multiplied by 35 years (to represent the lifetime avoided emissions). The $CO_2$ emissions produced by the New York electric grid from traditional fossil fuel–fired power plants that would be displaced by the Proposed Action are presented in Table 3.4-16. The Proposed Action would result in a net annual reduction of 1,357,865 tons of $CO_2$, which is the equivalent of the removal of 274,120 gasoline-powered passenger vehicles driven per year, with a lifetime reduction of 47,525,275 tons of $CO_2$.

The EPA's CO-Benefits Risk Assessment (COBRA) screening model Desktop Edition, Version 4.1 was used to estimate the health impacts of avoided emissions in the United States and in the combined area of Connecticut, Maryland, Massachusetts, New Jersey, New York, Rhode Island, and Virginia. The model used the following inputs: 2023 was selected as the analysis year to estimate the health impacts of emissions changes. New York was selected as the state where the emission changes would occur; Fuel Combustion: Electric Utility was the sector where the emission changes would occur; and the AVERT output file for the minimum annual avoided emissions for $NO_X$, $SO_2$, $PM_{2.5}$, VOC, and $NH_3$ was loaded into the COBRA application. The model provides estimated ranges of reduced occurrences of health events caused by air pollution, such as mortality, nonfatal heart attacks, and hospitalizations. It also estimates the total health benefit, which encompasses all saved costs of the avoided health events. COBRA includes a discount rate of either 3%, to account for the interest that may be earned from government backed securities, or 7%, to account for private capital opportunity costs. Monetary values presented are in 2017 dollars. The EPA recommends using both for a bounding approach. For the entire United States, COBRA estimates that the total health benefit ranges from $12,096,077 to $27,290,022 at a 3% discount rate and from $10,793,564 to $24,334,469 at a 7% discount rate. COBRA estimates statistical lives saved within the entire United States to range from 1.09 to 2.46 (EPA 2020b). For Connecticut, Maryland, Massachusetts, New Jersey, New York, Rhode Island, and Virginia, combined, COBRA estimates that the total health benefit ranges from $9,891,082 to $22,309,940 at a 3% discount rate and from $8,826,280 to $19,893,704 at a 7% discount rate. COBRA estimates statistical lives saved within Connecticut, Maryland, Massachusetts, New Jersey, New York, Rhode Island, and Virginia, combined, to range from 0.89 to 2.01 (EPA 2020b). For a 5-year estimate for the United States, the total health benefit ranges from $60,480,383 to $136,450,108 at a 3% discount rate and from $53,967,819 to $121,672,344 at a 7% discount rate. Over the course of 5 years, the statistical lives saved within the entire United States is between 5.44 and 12.31. This 5-year estimate is representative of the avoided emissions during operations only. This would represent a long-term **minor** beneficial impact due to avoided health events.

### Onshore Activities and Facilities

Air emissions and climate change: Onshore O&M activities would include periodic inspections, preventative maintenance, and regular equipment servicing. Table 3.4-12 presents the estimated onshore facilities O&M emissions for the Project. Annual O&M emissions from onshore facilities range from < 0.01% to 0.01% of Kent, Providence, and Washington Counties' annual emissions. Impacts on air quality from Project onshore facilities' O&M emissions would be **negligible** adverse.

**Table 3.4-12. Summary of Emissions from Onshore Facilities Operations and Maintenance (tpy)**

| Source, State | CO | $NO_X$ | $PM_{10}$ | $PM_{2.5}$ | $SO_2$ | VOC | $CO_2e$ |
|---|---|---|---|---|---|---|---|
| Onshore facilities, Rhode Island | 0.6 | 0.2 | 0.0 | 0.0 | 0.0 | 0.0 | 22 |
| **Total** | **0.6** | **0.2** | **0.0** | **0.0** | **0.0** | **0.0** | **22** |
| Percentage of Kent County, Rhode Island, emission inventory | < 0.01% | 0.01% | < 0.01% | < 0.01% | < 0.01% | < 0.01% | < 0.01% |
| Percentage of Providence County, Rhode Island, emission inventory | < 0.01% | < 0.01% | < 0.01% | < 0.01% | < 0.01% | < 0.01% | < 0.01% |
| Percentage of Washington County, Rhode Island, emission inventory | < 0.01% | 0.01% | < 0.01% | < 0.01% | < 0.01% | < 0.01% | < 0.01% |

Source: Tech Environmental (2023).

Decommissioning activities associated with the onshore facilities would not likely impact air quality in the region. Associated air emissions would occur 35 years in the future when air quality conditions, emissions technology, and regulations would be different; therefore, estimating decommissioning emission impacts now is speculative. Because portions of the Project would be decommissioned in place, fewer decommissioning activities and less equipment would be required; therefore emissions from decommissioning activities would be less than those from construction activities. There would be no further air emissions from RWF once decommissioning is complete.

## 3.4.2.3.3 Cumulative Impacts

### Offshore Activities and Facilities

Air emissions and climate change: Construction and installation, O&M, and decommissioning emissions associated with the Proposed Action would result in temporary moderate adverse, long-term minor adverse, and long-term minor beneficial impacts on air quality. The Proposed Action's construction emissions (see Tables 3.4-10 and 3.4-13) would noticeably increase emissions of regulated pollutants over the construction emissions generated by other offshore wind projects associated with the No Action

Alternative (see Table 3.4-5). Therefore, total cumulative construction-related air emissions from all planned offshore wind energy projects, including the Proposed Action, in the Massachusetts Wind Energy Area (MA WEA) would consist of an estimated 128,401 tons of $NO_X$, 2,697 tons of $SO_2$, 5,930 tons of $PM_{10}$, and 7,991,974 tons of $CO_2e$. However, these effects would be localized and would cease when Project construction is complete.

Table 3.4-13 combines the total estimated construction emissions contributed by the Proposed Action within the OCS air permit area with the estimated local construction emissions that occur beyond the OCS air permit area and within 15.5 miles of shore (RWF-New Jersey, RWF-Massachusetts, RWEC-Rhode Island, etc.). The totals are not compared to county emission inventories because only portions of the Proposed Action construction emissions generated offshore within the OCS air permit area would reach nearby counties, depending on wind conditions at the time of emission. The OCS air permitting process will require air dispersion modeling of these emissions to demonstrate compliance with the NAAQS.

**Table 3.4-13. Geographic Analysis Area Offshore Cumulative Construction Emissions (tpy)**

| Source, State | CO | $NO_X$ | $PM_{10}$ | $PM_{2.5}$ | $SO_2$ | VOC | $CO_2e$ |

Source: Tech Environmental (2023).

Notes:

RWF-Connecticut = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from the Port of New London.

RWF-New Jersey = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from the Paulsboro Marine Terminal.

RWF-Rhode Island = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from the Port of Providence and the Port of Davisville at Quonset Point.

RWEC-Rhode Island = the portion of RWEC offshore segment construction emissions that would occur outside the OCS permit area and within 15.5 miles of shore.

RWF-Maryland = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from Sparrow’s Point.

RWF-Massachusetts = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from the New Bedford Marine Commerce Terminal and during transit to and from European ports.

RWEC-Massachusetts = the portion of RWEC offshore segment construction emissions that would occur outside the OCS permit area and within 15.5 miles of shore.

RWF-Virginia = the portion of RWF construction emissions that would occur beyond the OCS permit area and within 15.5 miles of shore during transit to and from the Port of Norfolk and during transit to Sparrow’s Point.

RWEC-OCS = the portion of RWEC offshore segment construction emissions that would occur within the OCS permit area.

RWF-OCS = the portion of RWF construction emissions that occur within the OCS permit area.

Air quality impacts from O&M of the Proposed Action, provided in Tables 3.4-11 and 3.4-12, would combine with the air quality impacts from all other O&M activities that could occur under the No Action Alternative (see Table 3.4-8), albeit at lower emission quantities compared to the construction and installation period. O&M emissions would noticeably add emissions in localized areas, several times per year, for the life of the Project. Total cumulative operation-related air emissions from all of the planned wind projects, including the Proposed Action, in the Massachusetts WEA would consist of an estimated 3,788 tons of $NO_X$, 44 tons of $SO_2$, 137 tons of $PM_{10}$, and 757,202 tons of $CO_2e$.

Table 3.4-14 combines the total estimated annual O&M emissions contributed by the Proposed Action within the OCS air permit area with the estimated annual O&M emissions emitted by the Proposed Action within 15.5 miles of the on-land areas and port locations in New York (RWF-New York). When this summed conservative total is compared to the 2017 National Emission Inventory for Kings and Suffolk Counties, New York, Kings County would see a 0.2% to 7.8% increase (depending on the pollutant) in its regulated pollutant annual emissions, whereas Suffolk County would see a 0.06% to 5.2% increase in its regulated pollutant annual emissions. Similarly, Table 3.4-14 combines the total annual O&M emissions emitted by the Proposed Action within the OCS air permit area with the estimated annual O&M emissions emitted by the Proposed Action within 15.5 miles of the on-land areas and port locations in Rhode Island (RWF – Rhode Island). When this summed conservative total is compared to Washington County, Rhode Island's 2017 National Emission Inventory, there would be a 0.6% to 33.5% increase in its regulated pollutant annual emissions. These are very conservative estimated increases because not all of the annual O&M emissions generated within the OCS air permit area would impact each nearby county in turn. Instead, only a portion of emissions generated within the OCS air permit area would actually reach land, depending on wind conditions at the time of emission.

### Table 3.4-14. Geographic Analysis Area Offshore Cumulative Operations and Maintenance Emissions (tpy)

| Source, State | CO | $NO_X$ | $PM_{10}$ | $PM_{2.5}$ | $SO_2$ | VOC | $CO_2e$ |

Source: Tech Environmental (2023).

Notes:

RWF-New York = the portion of RWF O&M emissions that would occur outside the OCS permit area and within 15.5 miles from shore during transit to and from the Port of Montauk, Port Jefferson, and the Port of Brooklyn.

RWF-Rhode Island = the portion of RWF O&M emissions that would occur beyond the OCS permit area and within 15.5 miles from shore during transit to and from the Port of Providence and the Port of Davisville at Quonset Point.

RWF-OCS = the portion of RWF construction emissions that occur within the OCS permit area.

The Proposed Action would also have a noticeable contribution on existing GHG emissions. The construction and installation, O&M, and the eventual decommissioning of the Proposed Action would generate approximately 2,447,102 metric tons more $CO_2e$ emissions over the No Action Alternative within the OCS air permit area. However, these contributions are small in proportion to aggregate national and global emissions. In 2019, U.S. GHG emissions totaled 6,558 million metric tons of $CO_2e$ (EPA 2021c).

While cumulative air emissions in the region would increase during construction, the Project could also contribute to a long-term, cumulative net decrease in emissions by substituting some existing fossil fuel sources with a renewable source. As calculated in AVERT v4.1, the Proposed Action would avoid an estimated minimum of 235 tons of $NO_X$, 103 tons of $SO_2$, 41 tons of $PM_{2.5}$, 26 tons of VOC, 37 tons of $NH_3$, and 1,415,685 tons of $CO_2$ every year and would avoid an estimated maximum of 292 tons of $NO_X$, 126 tons of $SO_2$, 51 tons of $PM_{2.5}$, 33 tons of VOC, 46 tons of $NH_3$, and 1,771,439 tons of $CO_2$ every year by providing energy generation that existing fossil fuel–generated energy sources would have otherwise provided (EPA 2020c). This represents up to an estimated 5.3% to 6.2% increase in avoided emissions over the No Action Alternative on an annual basis. When combined with estimated avoided emissions from other offshore wind projects in the GAA, an estimated minimum of 4,582 tons of $NO_X$, 1,892 tons of $SO_2$, 803 tons of $PM_{2.5}$, 522 tons of VOC, 726 tons of $NH_3$, and 28,143,672 tons of $CO_2$ could cumulatively be avoided every year and an estimated maximum of 4,897 tons of $NO_X$, 2,017 tons of $SO_2$, 859 tons of $PM_{2.5}$, 559 tons of VOC, 776 tons of $NH_3$, and 30,111,159 tons of $CO_2$ could cumulatively be avoided every year.

Based on the above considerations, BOEM anticipates that the overall cumulative impacts associated with the Proposed Action when combined with other past, present, and reasonably foreseeable activities would be **moderate** adverse, although regional air quality could be improved over the Project life cycle when compared to the No Action Alternative.

The Social Cost of Carbon, now referred to as the Social Cost of GHG (SC-GHG), attempts to quantify the monetary value of net damages from climate change. The SC-GHG is the estimated cost resulting from the addition of GHG emissions to the atmosphere. SC-GHG values for use in analysis are derived on a per-metric ton basis for $CO_2$, $CH_4$, and $N_2O$ for each emission year from 2020 to 2050. Higher global warming potential GHGs such as $CH_4$ and $N_2O$ have a higher SC-GHG on a per metric ton basis than $CO_2$. The intention in the analysis is to include the value of all climate change impacts, including changes in net agricultural productivity, human health effects, property damage from increased flood risk natural disasters, disruption of energy systems, risk of conflict, environmental migration, and the value of ecosystem services (Interagency Working Group on Social Cost of Greenhouse Gases [IWG] 2021). EO 12866 (Regulatory Planning and Review) directs agencies to “base decisions on the best reasonably obtainable scientific, technical, economic, and other information.” EO 13990 (Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis) reinstates the IWG and directs it to publish an interim update to the SC-GHG, which includes a method to estimate the social cost of $CO_2$, $CH_4$, and $N_2O$. The interim SC-GHG estimates presented in *Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide* were published on February 26, 2021, and are used as the basis for this analysis (IWG 2021).

The interim SC-GHG estimates from IWG (2021) described above are used to contextualize GHG impacts in terms of economic damages. The cost attributable to 1 metric ton of each GHG emitted is estimated based on the year emitted and the estimated global economic damages discounted to their present value using the appropriate discount rate. The estimated costs in Table 3.4-15 were calculated for the Project based on the calculated emission estimates.

**Table 3.4-15. Social Cost of Greenhouse Gases from Revolution Wind Farm (2020 $)**

| Social Cost Metric | 5% Discount Rate – Average | 3% Discount Rate – Average | 2.5% Discount Rate – Average | 3% Discount Rate – 95th percentile |
|---|---|---|---|---|
| SC-$CO_2$ | $25,364,349 | $102,345,778 | $157,342,814 | $311,327,904 |
| SC-$CH_4$ | $12,119 | $31,504 | $43,031 | $83,838 |
| SC-$N_2O$ | $439,500 | $1,623,132 | $2,482,422 | $4,315,390 |
| **Total** | $25,815,968 | $104,000,414 | $159,868,267 | $315,727,133 |

Significant uncertainty exists in the SC-GHG estimates. Uncertainty is addressed in part through a combination of multi-model ensemble, probabilistic analysis, and scenario analysis. However, it is important to disclose that uncertainty is substantial (IWG 2021). These uncertainties do not all work in the same direction in terms of their influence on the SC-GHG estimates. However, it is the IWG's judgment that, taken together, the limitations suggest that the interim SC-GHG estimates presented in IWG (2021) likely underestimate the damages from GHG emissions. Uncertainties in the SC-GHG estimates stem from inherent uncertainties about what will happen in the future as well as known limitations in the models used to develop the SC-GHG estimates in IWG (2021).

### Onshore Activities and Facilities

Air emissions and climate change: Project onshore facilities would result in temporary to long-term negligible to minor adverse air emissions as a result of on-road and non-road equipment use. The Proposed Action onshore facility construction $NO_X$ emissions are approximately 5.5% of Providence County, Rhode Island's annual $NO_X$ emissions, 16.9% of Washington County, Rhode Island's annual $NO_X$ emissions and 20.3% of Kent County, Rhode Island's annual $NO_X$ emissions.

Most O&M annual emissions of regulated pollutants were between 0.29% and 2.94% of Kent, Providence, or Washington Counties' annual emissions. Annual O&M emissions from onshore facilities would have a negligible adverse impact, ranging from < 0.01% to 0.01% of Kent, Providence, and Washington Counties' annual emissions. When combined with other onshore sources of air emissions, cumulative impacts on air quality would be long term **minor** adverse.

## 3.4.2.3.4 Conclusions

Construction and installation and decommissioning activities would cause increased air emissions temporarily. Emission sources from O&M activities would primarily use vehicles and vessels that emit less emissions than during construction and installation and decommissioning activities, and fewer annual trips would be needed. Therefore, BOEM expects the impact on air quality from the Proposed Action alone to be **minor** adverse due to air emissions from construction activities. While cumulative air emissions in the region would increase during construction, it is important to note that the Proposed Action could also contribute to a long-term net decrease in emissions by substituting some existing fossil fuel sources with a renewable source. By substituting some fossil fuel sources with a renewable source with less emissions, the Proposed Action would generate long-term **minor** beneficial impacts to regional air quality by contributing to a long-term net decrease in emissions in the region.

Considering all the IPFs together, BOEM anticipates that the overall cumulative impacts associated with the Proposed Action when combined with other past, present, and reasonably foreseeable activities would remain **moderate** adverse, although regional air quality could be improved when compared to the No Action Alternative.

#### 3.4.2.4 Alternatives C, D, E, F

Table 3.4-5 provides a summary of IPF findings for these alternatives.

Using AVERT Version 4.1, avoided $CO_2$ emissions are calculated for the operational life of each alternative with a capacity factor of 45% (AVERT offshore wind default) and with a capacity between 704 MW and 891 MW for each alternative. Alternative F required a blend of capacity factors based on the seasonal variation in wind speeds in which the full 14-MW capacity of the turbines could be used in the four winter months between November and March with lower speeds throughout the rest of the year, resulting in a functional maximum capacity of 12 MW. This led to an adjusted annual capacity factor of 40.3%.

Table 3.4-16 contains the associated annual $CO_2e$ emissions (and avoided $CO_2$ emissions) for Alternatives C through F. Alternative C1, excluding up to 35 WTG, is equivalent to 309,000 vehicles removed annually. Alternative C2, excluding up to 36 WTGs, has avoided GHG emissions equivalent to the removal of 304,229 vehicles per year. Alternative D, which excludes or relocates up to 22 WTGs, has net GHG emissions equivalent to the removal of 352,254 vehicles per year. Alternative E1, which excludes up to 36 WTGs, while also assuming a capacity of 11 MW, is an equivalent to the removal of 278,322 vehicles per year. Alternative E2, which excludes up to 19 WTGs and also assumes a capacity of 11 MW, has avoided GHG emissions equivalent to the removal of 352,668 vehicles per year. Alternative F would exclude up to 44 WTGs and assumes a capacity of 14 MW, has avoided GHG emissions equivalent to the removal of 249,405 vehicles per year. These figures are relative to the existing grid configuration, but the actual annual quantity of avoided emissions attributable to this proposed facility is expected to diminish over time if the electric grid becomes greener due to the addition of other renewable energy facilities and retirement of high-emitting generators.

##### 3.4.2.4.1 Conclusions

Although Alternatives C through F would reduce the number of allowable WTGs and their associated IACs, which would likely have an associated reduction in associated vessel and equipment use and air emissions, BOEM expects the impacts from each alternative would be similar to the Proposed Action: **minor** adverse due to air emissions from construction activities. Project O&M would also contribute to long-term **minor** beneficial impacts by substituting some fossil fuel sources of electricity generation with a lower emitting renewable source and thus, would result in a net reduction in cumulative air emissions in the region.

In the context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that each alternative's impacts would be similar to the Proposed Action (with individual IPFs leading to impact that would be short term **minor** adverse and long term **minor** beneficial). The overall cumulative impacts of each alternative on air quality when combined with past, present, and reasonably foreseeable activities would therefore be the same as under the Proposed Action: **moderate** adverse, with potential regional improvements to air quality when compared to the No Action Alternative. Overall adverse effects would be notable, but the resource would recover completely from adverse impacts.

#### 3.4.2.5 Alternative G

Table 3.4-5 provides a summary of IPF findings for this alternative.

Using AVERT Version 4.1, avoided $CO_2$ emissions are calculated for the operational life of Alternative G with a capacity factor of 45% (AVERT offshore wind default) and with a capacity of 704 MW. Table 3.4-16 contains the associated annual $CO_2e$ emissions (and avoided $CO_2$ emissions) for Alternative G compared to the other alternatives. Alternative G excludes 35 WTGs, assumes a capacity of 704 MW, and has avoided GHG emissions equivalent to the removal of 278,206 gasoline-powered passenger vehicles per year.

##### 3.4.2.5.1 Conclusions

Although Alternative G would reduce the number of allowable WTGs and their associated IACs, which would likely have an associated reduction in associated vessel and equipment use and air emissions, BOEM expects the impacts from this alternative would be similar to the Proposed Action—**minor** adverse—due to air emissions from construction activities. Project O&M would also contribute to long-term **minor** beneficial impacts by substituting some fossil fuel sources of electricity generation with a lower emitting renewable source and therefore would result in a net reduction in cumulative air emissions in the region.

In the context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that the alternative's impacts would be similar to the Proposed Action (with individual IPFs leading to impacts that would be short term **minor** adverse and long term **minor** beneficial). The overall cumulative impacts of this alternative on air quality when combined with past, present, and reasonably foreseeable activities would therefore be the same as under the Proposed Action: **moderate** adverse, with potential regional improvements to air quality when compared to the No Action Alternative. Overall, adverse effects would be notable, but the resource would recover completely from adverse impacts.

**Table 3.4-16 Avoided Emissions and Lifetime Net Emissions for Each Alternative**

| Alternative | Quantity of WTGs | Year 1 $CO_2e$ Emissions (tons) | Annual $CO_2e$ Emissions for Years 2–36 (tpy) | Annual Avoided CO2 Emissions for Years 2–36 (tpy) | Net Annual $CO_2e$ Emissions for Years 2–36 (tpy) | Operational Lifetime Net $CO_2e$ Emissions (tons) |
|---|---|---|---|---|---|---|
| Alternative A (No Action Alternative) | 0 WTG | 0 | 0 | 0 | 1,415,685 | 49,548,975 |
| Alternative B (Proposed Action) at 704 MW | 100 WTGs | 282,268 | 57,820 | 1,415,685 | -1,357,865 | -47,525,275 |
| Alternative B (Proposed Action) at 880 MW | 100 WTGs | 282,268 | 57,820 | 1,771,439 | -1,713,619 | -59,976,665 |
| Alternative C1 (12 MW) at 780 MW | 65 WTGs | 183,474 | 37,583 | 1,568,224 | -1,530,641 | -53,572,431 |
| Alternative C2 (12 MW) at 768 MW | 64 WTGs | 180,652 | 37,005 | 1,544,014 | -1,507,009 | -52,745,310 |
| Alternative D (all at 12 MW) at 888 MW | 74 WTGs | 208,878 | 42,787 | 1,787,691 | -1,744,904 | -61,071,645 |
| Alternative E1 (11 MW) at 704 MW | 64 WTGs | 180,652 | 37,005 | 1,415,685 | -1,378,680 | -48,253,807 |
| Alternative E2 (11 MW) at 891 MW | 81 WTGs | 228,637 | 46,834 | 1,793,789 | -1,746,954 | -61,143,405 |
| Alternative F (14 MW) at 704 MW | 56 WTGs | 158,070 | 32,379 | 1,267,816 | -1,235,436 | -43,240,275 |
| Alternative G (11 MW) at 704 MW | 65 WTG | 183,474 | 37,583 | 1,415,685 | -1,378,102 | -48,233,570 |

#### 3.4.2.6 Mitigation

No potential additional mitigation measures by BOEM for air quality are identified in Table F-3 in Appendix F. Any BOEM COP approval (with or without modifications) would require that Revolution Wind obtain an OCS air permit and comply with all permit requirements during construction activities. The EIS analysis assumes compliance with all other federal and state permit requirements under other statutes when evaluating impacts. Because any mitigation measures under the OCS air permit would be required no matter the alternative selected by BOEM, the application of those mitigation measures would not result in a change in impact-level determinations between the Proposed Action and Alternative G.

## 3.5 Bats

### 3.5.1 Description of the Affected Environment and Environmental Consequences of the No Action Alternative for Bats

Geographic analysis area: Although historical anecdotal observations of bats up to 1,212 miles (1,950 km) offshore North America exist, recent offshore observations of tree bats range from 10.5 to 26.0 miles (16.9–41.8 km) (Hatch et al. 2013). For this reason, and to capture most of the movement range for migratory bat species, the GAA for bats consists of the United States coastline from Maine to Florida and extends 100 miles (160.9 km) offshore and 5 miles (8.05 km) inland to capture the movement range for species in this group (Figure 3.5-1).

Northern long-eared bat (*Myotis septentrionalis*), which has been recently reclassified as endangered under the ESA as of November 30, 2022 (USFWS 2022), and other cave bats typically do not occur on the OCS. Tree bats are long-distance migrants; their range includes most of the Atlantic Coast from Florida to Maine. Although these species have been documented on the open ocean and could encounter WTGs, use of offshore habitat is thought to be limited and generally restricted to spring and fall migration. The onshore limit of the GAA is 0.5 mile (0.8 km) inland to cover onshore habitats used by the bat species that may be affected by offshore components of the proposed Project as well as those species that could be affected by proposed onshore Project components. The onshore limit of the GAA is intended to cover most of the onshore habitat used by those bat species that may encounter the Project during most of their life cycles.

Affected environment: This section provides information on existing bat species and habitat trends from past and present activities. Bats within the GAA are subject to pressure from ongoing activities generally associated with onshore impacts, including onshore construction and climate change. Onshore construction activities and associated impacts are expected to continue at current trends and have the potential to result in impacts on bat species. The Vineyard Wind Final EIS (BOEM 2021a), the South Fork Wind Farm (SFWF) Final EIS (BOEM 2021b), and COP Appendix AA (Biodiversity Research Institute [BRI] 2023) provide detailed discussions of existing bat resources as well as bat species and habitat trends along the East Coast, which are incorporated by reference. Appendix E1 of this EIS provides additional information regarding past and present activities and associated impacts to bats.

Eight bat species are present in the state of Rhode Island, five of which are likely year-round residents. Bat species that may occur in the offshore and onshore portions of the Lease Area are the long-distance migrants and the non-migrating cave-dwelling bats. Long-distance migrants consist of hoary bat (*Lasiurus cinereus*), eastern red bat (*Lasiurus borealis*), and silver-haired bat (*Lasionycteris noctivagans*). Non-migratory cave dwellers consist of northern long-eared bat, little brown bat (*Myotis lucifugus*), eastern small-footed bat (*Myotis leibii*), big brown bat (*Eptesicus fuscus*), and tri-colored bat (*Perimyotis subflavus*) (see Table 2-3 in COP Appendix AA [BRI 2023]). Both groups of bats are nocturnal insectivores that use a variety of forested and open habitats for foraging during the summer (Barbour and Davis 1969). Cave-hibernating bats are generally not observed offshore (Dowling and O’Dell 2018) and in winter migrate from summer habitat to hibernacula in the region (Maslo and Leu 2013). Migratory tree bats fly to southern parts of the United States in the winter and have been observed offshore during migration (Hatch et al. 2013; Stantec Consulting Services Inc. [Stantec] 2016, 2018).

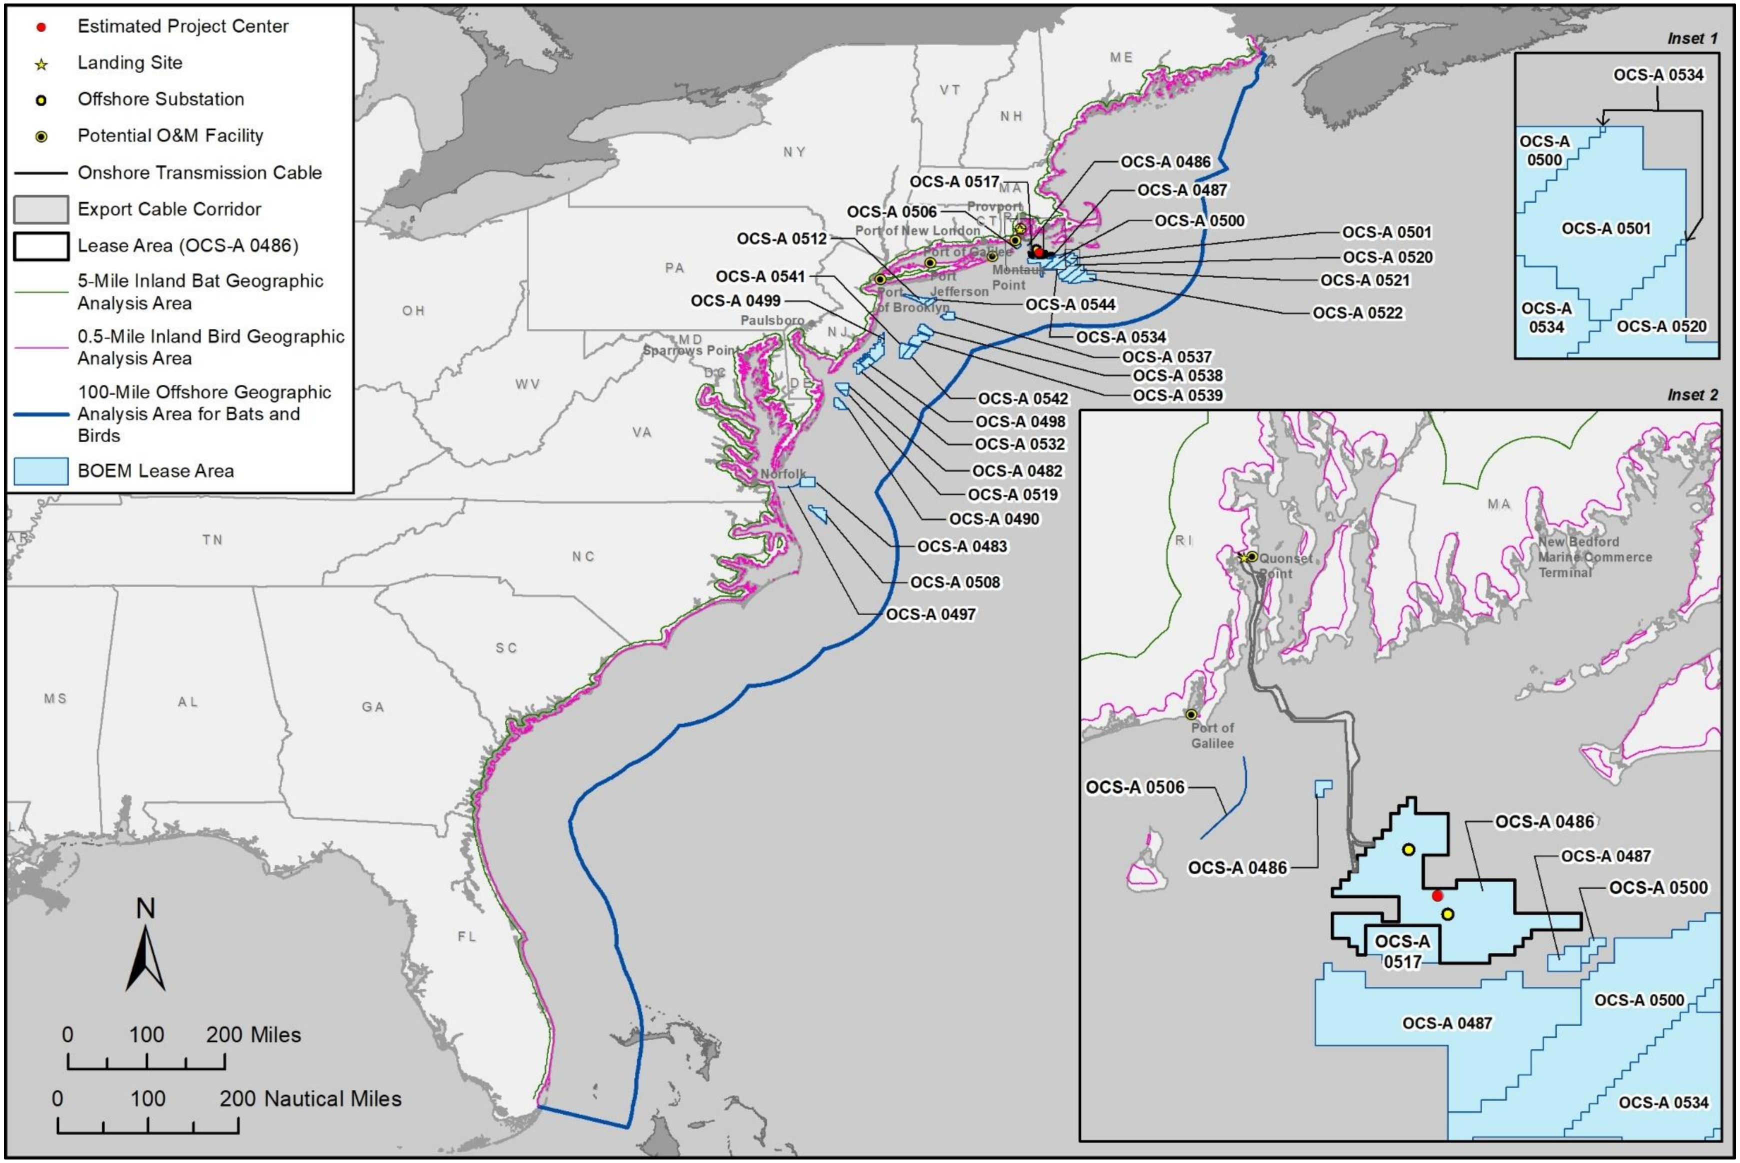

**Figure 3.5-1. Geographic analysis area for bats.**

**Offshore**

Although there is uncertainty on the specific movements of bats offshore, bats have been documented using the marine environment in the United States (Cryan and Brown 2007; Dowling and O'Dell 2018; Grady and Olson 2006; Hatch et al. 2013; Johnson et al. 2011; Stantec 2016). Bats have been observed to temporarily roost on structures, such as lighthouses on nearshore islands (Dowling et al. 2017). There is also historical evidence of bats, particularly eastern red bats, migrating offshore in the Atlantic (Hatch et al. 2013). In a Mid-Atlantic bat acoustic study conducted during the spring and fall of 2009 and 2010 (86 nights), the maximum distance that bats were detected from shore was 13.6 miles (21.9 km), and the mean distance was 5.2 miles (8.4 km) (Sjollema et al. 2014). In Maine, bats were detected on islands up to 25.8 miles (41.6 km) from the mainland (Peterson et al. 2014). In the Mid-Atlantic acoustic study (Sjollema et al. 2014), eastern red bats made up 78% (166 bat detections during 898 monitoring hours) of all bat detections offshore. This study also found that bat activity decreased as wind increased (Sjollema et al. 2014). In addition, eastern red bats were detected in the Mid-Atlantic up to 27.3 miles (44 km) offshore, outside the vicinity of islands or other structures, by high-resolution video aerial surveys (Hatch et al. 2013). Shipboard acoustic surveys conducted by Stantec in 2017 detected over 900 bat passes (primarily long-distance migratory tree bats) within the adjacent proposed SFWF Lease Area, export cable route, and adjacent offshore and coastal areas. Eastern red bats accounted for 69% of calls detected, whereas silver-haired bats accounted for 13%. All other species accounted for less than 5% of calls that were identified to species level. Peak detections for all species occurred during the month of August, suggesting that most offshore movement is associated with fall migration (Stantec 2018).

Several studies highlight the relationship between bat activity and weather conditions. Acoustic monitoring within the footprint of the proposed SFWF in southern New England found 82% of recorded bat passes with corresponding weather data occurred when wind speeds were < 5.0 meters/second (m/s) and temperatures were ≥ 15.0°C (Stantec 2018). This occurred during 49% of nighttime hourly rounded weather data increments during the monitoring period from July 14 to November 15. These weather conditions most often occurred from August through September. Bat activity occurred primarily during nights with warmer temperatures and low wind speeds, which has been likewise documented in several other studies (Fiedler 2004; Reynolds 2006; Stantec 2016). Similar monitoring at the operational Block Island Wind Farm in Rhode Island found that 90% of bat passes occurred at times when wind speeds were below 5.0 m/s and temperatures were at or above 15.0°C (Stantec 2018). Both studies reported very little activity at temperatures below 15.0°C, and most activity was documented at wind speeds between 2 and 4 m/s. Smith and McWilliams (2016) developed predictive models of regional nightly bat activity using continuous acoustic monitoring at several locations in coastal Rhode Island. Bat activity was found to steadily decrease with decreasing temperatures, and departures from seasonally normal temperatures increasingly inhibited bat activity later in the season (September through October). This study found no association between wind speed and bat activity, which contrasts with most other literature that shows bat activity is associated with relatively low wind speeds (Arnett et al. 2008; Cryan and Brown 2007; Fiedler 2004; Kerns et al. 2005), although wind speed data were regional and not site specific.

Cave-hibernating bats hibernate regionally in caves, mines, and other structures and primarily feed on insects in terrestrial and freshwater habitats. These species generally exhibit lower activity in the offshore environment than migratory tree bats (Sjollema et al. 2014), with movements primarily occurring during the fall. In the region, the maximum distance *Myotis* bats were detected offshore was 7.2 miles (11.5 km) (Sjollema et al. 2014). A recent nanotag tracking study on Martha's Vineyard recorded little brown bat (n = 3) movements off the island in late August and early September, with one individual flying from Martha's Vineyard to Cape Cod (Dowling et al. 2017). Big brown bats (n = 2) were also detected migrating from the island later in the year (October–November) (Dowling et al. 2017). These findings are supported by an acoustic study conducted on islands and buoys in the Gulf of Maine that indicated the greatest percentage of activity in July–October (Peterson et al. 2014). Presence in the Lease Area is considered rare for this group given the use of the coastline as a migratory pathway by cave-hibernating bats is likely limited to their fall migration period; acoustic studies indicate lower use of the offshore environment by cave-hibernating bats; and cave-hibernating bats do not regularly feed on insects over the ocean (BRI 2023).

Tree bats migrate south to overwinter and have been documented in the GAA's offshore environment (Hatch et al. 2013; Stantec 2018, 2019). Eastern red bats have been detected migrating from Martha's Vineyard late in the fall, with one individual tracked as far south as Maryland (Dowling et al. 2017). These results are supported by historical observations of eastern red bats offshore as well as recent acoustic survey results (Hatch et al. 2013; Peterson et al. 2014; Sjollema et al. 2014). Although little local data are available, shipboard and stationary acoustic surveys recorded several observations of bats flying over the ocean, with detections of migratory tree bats near the Lease Area (Stantec 2018). Tree bats may pass through the Lease Area during the migration period because they have been detected in the offshore environment primarily during late summer and fall. However, because bat movement offshore is generally limited to fall migration and bat activity offshore primarily occurs during wind speeds below 5.0 m/s, exposure to the Lease Area is expected to be relatively low as the average wind speeds in the Lease Area are between 5 and 10 m/s with stronger wind in the winter (BRI 2023:Section 4.2.4.1). Therefore, there is little evidence of bat use of the offshore environment and a relatively low proportion of the population is exposed.

**Onshore**

In July 2020, VHB performed acoustic presence-absence surveys for the federally threatened northern long-eared bat along the onshore transmission cable route and within the proposed OnSS parcel (VHB 2023a). Automated and qualitative analysis of acoustic data did not detect presence of the northern long-eared bat or the tri-colored bat, which is a candidate species for listing under the Endangered Species Act (ESA). Call data were auto classified with Bat Call Identification East, Version 2.8b, which resulted in the detection of the following species: big brown bat (n = 540 calls), eastern red bat (n = 891 calls), hoary bat (n = 23 calls), and silver-haired bat (n = 130 calls). Qualitative analysis of unknown species of concern calls confirmed 11 big brown bat calls and 135 eastern red bat calls (VHB 2023a).

**Special-Status Bat Species**

The official species list generated by the USFWS's Information for Planning and Consultation (IPaC) planning tool. on September 28, 2019, indicates that the federally endangered northern long-eared bat has the potential to occur within the footprint of the onshore facilities (VHB 2023b). The IPaC list also indicates that there are no critical habitats associated with the northern long-eared bat within the GAA. The range of the federally endangered Indiana bat (*Myotis sodalis*) does not include Rhode Island, and historical records of the Indiana bat demonstrate its presence only in Berkshire and Hampden Counties in Massachusetts (last recorded in 1939; Mass.gov 2019); however, a single tagged Indiana bat was detected in 2015 on Cape Cod and Nantucket (Motus Wildlife Tracking System 2015). The Indiana bat is also not among species of bats documented offshore (Pelletier et al. 2013; Stantec 2016). For these reasons, this assessment focuses solely on the potential occurrence of the northern long-eared bat within the GAA.

BOEM prepared a biological assessment (BA) for the potential effects on USFWS federally listed species under Section 7 of the ESA (BOEM 2022, 2023). The BA, as amended, was submitted to the USFWS on November 17, 2022, requesting initiation of consultation under Section 7 of the ESA, and the USFWS responded on November 25, 2022, with a letter of consultation initiation. The BA found that the Proposed Action *may affect but is not likely to adversely affect* listed species (BOEM 2022, 2023). BOEM requested concurrence on its conclusion that the impacts of the proposed onshore activities are expected to be discountable and insignificant and thus *may affect but are not likely to adversely affect* northern long-eared bat. There is no critical habitat designated for this species. In its final biological opinion, dated May 30, 2023, the USFWS concurred with BOEM's determination that the Project *may affect but is not likely to adversely affect* the northern long-eared bat because the best available information indicates the likelihood of the species occurring in the Lease Area is discountable (USFWS 2023).

Offshore, northern long-eared bats are generally not expected to occur within the Lease Area. A recent tracking study on Martha's Vineyard (n = 8; July–October 2016) did not record any offshore movements, and bats were presumed to hibernate on the island (Dowling et al. 2017). However, shipboard acoustic sampling near the SFWF detected a single northern long-eared bat call 21.1 miles (34 km) offshore (Stantec 2018). Most other northern long-eared bat passes detected during these surveys were 3 to 9 miles (5–14 km) offshore. Stationary acoustic detectors positioned on two turbines within the operational Block Island Wind Farm did not detect any northern long-eared bat calls (Stantec 2018, 2020). Similarly, vessel-based surveys at the construction site of the Block Island Wind Farm in 2016 did not detect any *Myotis* species (Stantec 2016). If northern long-eared bats were to migrate over water, most movements would likely be near the mainland. The related little brown bat has been documented migrating from Martha's Vineyard to Cape Cod, and northern long-eared bats may likewise migrate to mainland hibernacula from these islands in August and September (Dowling et al. 2017). Given there is little evidence of use of the offshore environment by northern long-eared bats and exposure is expected to be minimal, this species is not further assessed in the offshore environment. This conclusion is also consistent with the Vineyard Wind BA (BOEM 2020).

## 3.5.2 Environmental Consequences

### 3.5.2.1 Relevant Design Parameters, Impact-Producing Factors, and Potential Variances in Impacts

This assessment analyzes the maximum-case scenario; however, there is the potential for variances in the proposed Project build-out, as defined in the PDE (see Appendix D). The Project design parameters that would influence the magnitude of the impacts on bats include the number, size, and location of WTGs; the location of the OnSS and ICF; the type of lighting to be used; the location of construction within the landfall work area and within the transmission cable envelope; and the time of year during which construction occurs. Impacts associated with construction of the onshore elements of the Proposed Action during the active season for bats (generally April through October) could be avoided if onshore construction occurs outside this time frame.

The following EPMs would be implemented to minimize potential impacts to bats (see Appendix F, Table F-1):

- Revolution Wind evaluated siting alternatives for the OnSS using the criteria that included avoidance or minimization of disturbance to ecologically sensitive areas.
- Revolution Wind is committed to an indicative layout scenario with WTGs sited in a grid with approximately 1.15-mile (1-nm) × 1.15-mile (1-nm) spacing that aligns with other proposed adjacent offshore wind projects in the RI/MA WEA. This wide spacing of WTGs would allow avian and bat species to avoid individual WTGs and minimize risk of potential collision.
- The OnSS and ICF would be located on parcels that are already highly altered and include buried demolition waste.
- The transmission cable would be located primarily in unvegetated and previously disturbed or developed ROWs.
- To the extent feasible, tree and shrub removal for onshore facilities would occur outside the avian nesting and bat roosting period (May 1 through August 15). If tree and shrub removal cannot be avoided during this season, Revolution Wind would coordinate with appropriate agencies to determine appropriate course of action.
- Construction and operational lighting would be limited to the minimum necessary to ensure safety and to comply with applicable regulations.
- Revolution Wind would comply with FAA and USCG requirements for lighting while using lighting technology (e.g., low-intensity strobe lights) that minimize impacts on avian and bat species.
- Accidental spill or release of oils or other hazardous materials offshore would be managed through the OSRP.
- An SESC plan, including erosion and sedimentation control measures, would be implemented to minimize potential water quality impacts during construction and operation of the onshore facilities.
- Onshore facilities would be sited within previously disturbed and developed areas to the extent practicable.
- The onshore transmission cables would be buried and would therefore avoid the risk to avian and bat species associated with overhead lines.
- Revolution Wind would document any dead (or injured) birds/bats found incidentally on vessels and structures during construction, O&M, and decommissioning and provide an annual report to BOEM and USFWS.
- Revolution Wind would continue to coordinate with RIDEM and NOAA NMFS regarding TOY restrictions through the permitting process and would adhere to requirements imposed by these agencies.
- Revolution Wind previously committed to compliance with the northern long-eared bat 4(d) Rule (USFWS 2016b) to avoid and minimize long-term impacts on the species and sensitive upland habitats. However, the change in status from threatened to endangered nullified the prior 4(d) Rule that tailored protections for the species when it was listed as threatened. New interim

guidelines and protections have been issued by the USFWS. Revolution Wind would continue to coordinate with RIDEM and the USFWS to avoid and minimize adverse effects to northern long eared bats and would adhere to requirements imposed by these agencies.

These EPMs would be implemented across all alternatives; therefore, BOEM would not expect measurable potential variances in impacts across the alternatives.

See Appendix E1 for a summary of IPFs analyzed for bats across all action alternatives. IPFs that are either not applicable to the resource or determined by BOEM to have a negligible adverse impact are excluded from Chapter 3 and provided in Table E1-4 in Appendix E1. Offshore and onshore IPFs are addressed separately in the analysis if appropriate for the resource; not all IPFs have both an offshore and onshore component. Where feasible, calculations for specific alternative impacts are provided in Appendix E4, to facilitate reader comparison across alternatives.

Table 3.5-1 discloses IPF findings carried forward for analysis in this section. Each alternative analysis discussion consists of the construction and installation phase, the O&M phase, the decommissioning phase, and the cumulative analysis. If these analyses are not substantially different, then they are presented as one discussion.

The overall impact to bats from any action alternative would be **minor** adverse, as the effects would be small, and the resource would recover completely, with no mitigating action required. The conclusion section for each alternative analysis provides additional rationale for this impact determination.

**Table 3.5-1. Alternative Comparison Summary for Bats**

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTGs | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
|---|---|---|---|---|---|---|---|
| Cable emplacement/ maintenance | Only small amounts of habitat removal, if any, would be required by onshore power infrastructure construction and would occur in previously disturbed areas. Temporary to short-term impacts associated with habitat loss or avoidance during cable emplacement/maintenance may occur, but no injury or mortality of bat individuals would be expected. Cable emplacement/maintenance is therefore expected to have **negligible** adverse impacts on bats. | **Onshore**: The onshore transmission cable route would be located primarily in unvegetated and previously disturbed or developed ROWs that do not provide high-quality habitat for bats; however, some of the alternative routes under consideration within the transmission cable envelope contain segments that would pass through undeveloped, vegetated areas comprised of upland forest and shrubland. The preferred transmission cable route is an approximate 1-mile (1.6-km) route that would predominantly follow along paved roads or previously disturbed areas such as parking lots. Based on Project timing, the limited area of effect relative to available habitat, and the proposed impact avoidance and minimization measures, adverse construction impacts of the Proposed Action on northern long-eared bat would be **negligible** adverse.<br>O&M impacts resulting from vegetation clearing would be reduced by observing time-of-year restrictions on vegetation removal to avoid bats' breeding season and therefore, **negligible** adverse. Impacts from land disturbance during decommissioning would be similar to those described within the construction impact analysis, although the impacts would likely be less because new vegetation clearing and grading would not be necessary.<br>Onshore construction and installation would add to other limited onshore bat habitat disturbance actions through the removal of approximately 1.6 acres (0.6 ha) of mixed oak/white pine forest at the ICF but would not result in population-level effects given the limited amount of habitat removal and the presence of high-quality habitat in the vicinity. Therefore, the cumulative impact of the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in short-term **negligible** to **minor** adverse impacts to bats. | **Onshore**: Alternatives C through F would not alter onshore activities. Therefore, construction, O&M, and decommissioning impacts would be the same as the Proposed Action: short term **negligible** adverse. Likewise, cumulative impacts would be the same as the Proposed Action: short term **negligible** to **minor** adverse impacts. | | | | **Onshore**: Similar to Alternatives C through F, Alternative G would not alter onshore activities, and construction, O&M, and decommissioning impacts would be the same as the Proposed Action: short term **negligible** adverse. Likewise, cumulative impacts would be the same as the Proposed Action: short term **negligible** to **minor** adverse. |
| Light | Lighting sources on the WTGs and OSSs may serve as an attractant to bats as they navigate, or bats may be indirectly attracted to insect prey drawn to the lights. But based on collision mortalities | **Offshore**: Bats may demonstrate attraction to or avoidance of construction vessels installing offshore facilities. Exposure to vessels and installation infrastructure would be temporally limited to the construction period. Thus, behavioral | **Offshore**: No measurable change from Proposed Action construction impacts is anticipated for Alternatives C through F because the number and duration of construction vessels and work areas requiring nighttime lighting would be the same as described for the Proposed Action. | | | | **Offshore**: Similar to Alternatives C through F, there is no measurable change from Proposed Action construction impacts anticipated for Alternative G, and impacts to bats from offshore lighting under this |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTGs | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
|---|---|---|---|---|---|---|---|
| | documented at onshore wind farms, the behavioral vulnerability to collision due to offshore lighting for all bat species would be **negligible** adverse. | changes due to lighting on construction vessels would be temporary, and impacts to bats would be **negligible** adverse, with long-distance migratory bats most at risk because they are most likely to seasonally occur in the airspace of the RWF.<br>Lighting during the O&M phase of the Project would be limited, which should reduce insect and potential bat attraction (Stantec 2018). Revolution Wind would comply with FAA (2018) and BOEM (2021c) requirements for lighting while using lighting technology (e.g., low-intensity strobe lights) that minimize impacts on bat species. Overall, collision-related mortality or injury from lighting at the offshore facilities could result in **negligible** to **minor** adverse impacts to bats at the RWF, with long-distance migratory bats most at risk because they are most likely to seasonally occur in the airspace of the RWF.<br>The Proposed Action would add up to 100 new WTGs with red flashing aviation hazard lighting to the offshore environment. Vessel lights during construction and installation, O&M, and decommissioning would be minimal and limited to vessels transiting to and from construction areas. Ongoing and future non–offshore wind activities are expected to cause permanent impacts, primarily driven by light from offshore structures and short-term and localized impacts from vessel lights. For these reasons, the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in long-term **negligible** to **minor** adverse cumulative impacts to bats, with long-distance migratory bats most at risk because they are most likely to seasonally occur in the Lease Area. | Alternatives C through F would reduce operational nighttime lighting due to a reduced number of lighted structures, thereby negligibly decreasing the risk of bat injury or mortality from collision with WTGs. However, impacts to bats from offshore lighting under these alternatives would likely be the same as the Proposed Action: **negligible** to **minor** adverse.<br>Alternatives C through F would add up to 56 to 93 new WTGs with red flashing aviation hazard lighting to the offshore environment. Additionally, marine navigation lighting would include one or more flashing white lights on each WTG and the OSSs and would be directed out and down to the water surface. Vessel lights during construction and installation, O&M, and decommissioning would be minimal and limited to vessels transiting to and from construction areas. These lights could serve as an attractant to bats as they navigate, or bats may be indirectly attracted to insect prey drawn to the lights. Ongoing and future non–offshore wind activities are expected to cause permanent impacts, primarily driven by light from offshore structures and short-term and localized impacts from vessel lights. For these reasons, Alternatives C through F, when combined with past, present, and reasonably foreseeable activities would result in long-term **negligible** to **minor** adverse cumulative impacts to bats, with long-distance migratory bats most at risk because they are most likely to seasonally occur in the Lease Area. | | | | alternative would likely be the same as the Proposed Action: **negligible** to **minor** adverse.<br>Alternative G would add 65 WTGs with red flashing aviation hazard lighting to the offshore environment. Additionally, marine navigation lighting would include one or more flashing white lights on each WTG and the OSSs and would be directed out and down to the water surface. Vessel lights during construction and installation, O&M, and decommissioning would be minimal and limited to vessels transiting to and from construction areas. These lights could serve as an attractant to bats as they navigate, or bats may be indirectly attracted to insect prey drawn to the lights. Ongoing and future non–offshore wind activities are expected to cause permanent impacts, primarily driven by light from offshore structures and short-term and localized impacts from vessel lights. For these reasons, Alternative G, when combined with past, present, and reasonably foreseeable activities would result in long-term **negligible** to **minor** adverse cumulative impacts to bats, with long-distance migratory bats most at risk because they are most likely to seasonally occur in the Lease Area. |
| | | **Onshore**: Most construction activities would occur during the day over the approximately 1-year construction period for the onshore facilities, impacts from lighting on bats would be **negligible** adverse.<br>During the O&M of the OnSS and ICF, general yard lighting would be used for assessment of equipment. In general, lighting would be off at night unless there is work in progress or lights are left on for safety and security purposes. Because the use of lighting at night is expected to be | **Onshore**: Alternatives C through F would not alter onshore activities. Therefore, impacts would be the same as the Proposed Action: temporary to short term **negligible** adverse. | | | | **Onshore**: Similar to Alternatives C through F, Alternative G would not alter onshore activities, and impacts would be the same as the Proposed Action: temporary to short term **negligible** adverse. |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTGs | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
|---|---|---|---|---|---|---|---|
| | | infrequent, the impacts it has on temporary bat displacement and/or behavior disruption would be **negligible** adverse.<br>Lighting from construction and operations could add to baseline light sources and activities associated with other onshore projects. When considered in the context of the other nearby commercial and industrial lighting within the GAA, BOEM expects **negligible** adverse cumulative impacts to bats. | | | | | |
| Noise | Anthropogenic noise on the OCS associated with future offshore wind development, including noise from pile driving and construction activities (e.g., use of noise-producing heavy equipment or machinery), could impact bats on the OCS. Construction activity would be temporary to short term and highly localized; however, no auditory impacts on bats would be expected.<br>Given the temporary and localized nature of potential impacts and bats' expected biologically insignificant response, impacts on bats are expected to be **negligible** adverse. No individual fitness (i.e., a bat's ability to survive and reproduce) or population-level impacts would occur as a result of onshore or offshore noise associated with future offshore wind development. | **Offshore**: Pile-driving noise and offshore construction noise associated with the Proposed Action would temporary to short term, and is expected to result in **negligible** adverse impacts.<br>Increases in activity and associated disturbances during RWF maintenance activities would have a short-term **negligible** adverse impact on bats because of the limited additional vessel activity and relatively low likelihood of bat occurrence near the RWF. There would also be no impacts to bats during O&M of the offshore RWEC because these components are underwater, and there would be no routine maintenance at these components.<br>Pile-driving and other construction noise and activity associated with the Proposed Action would add to baseline noise and activity associated with other offshore wind projects with overlapping construction periods. Therefore, the cumulative impact of the Proposed Action when combined with other past, present, and reasonably foreseeable projects would result in short-term **negligible** to **minor** adverse impacts to bats. | **Offshore**: Alternatives C through F would slightly decrease construction impacts on bats from noise associated with pile driving for WTGs as compared to the Proposed Action. Impacts, if any, would be temporary, limited to behavioral avoidance, and localized and would be the same as the Proposed Action: short term **negligible** adverse.<br>No measurable change from Proposed Action O&M impacts is anticipated because operational noise sources and levels would be the same: short term **negligible** adverse.<br>Pile-driving and other construction noise and activity associated with Alternatives C through F would add to baseline noise and activity associated with other offshore wind projects with overlapping construction periods. However, Alternatives C through F's contribution would be limited in duration and cease when construction ends. Therefore, these alternatives when combined with other past, present, and reasonably foreseeable projects would result in short- to long-term **negligible** to **minor** adverse cumulative impacts to bats. | | | | **Offshore**: Similar to Alternatives C through F, Alternative G would slightly decrease construction impacts on bats from noise associated with pile driving for WTGs as compared to the Proposed Action, and impacts, if any, would be temporary, limited to behavioral avoidance, and localized and would be the same as the Proposed Action: short term **negligible** adverse.<br>No measurable change from Proposed Action O&M impacts is anticipated because operational noise sources and levels would be the same: short term **negligible** adverse.<br>Pile-driving and other construction noise and activity associated with Alternative G would add to baseline noise and activity associated with other offshore wind projects with overlapping construction periods. However, Alternative G's contribution would be limited in duration and cease when construction ends. Therefore, this alternative when combined with other past, present, and reasonably foreseeable projects would result in short- to long-term **negligible** to **minor** adverse cumulative impacts to bats. |
| | | **Onshore**: Some potential for temporary to short-term, and localized habitat impacts arising from onshore construction noise exists; however, no auditory impacts on bats would be expected. Therefore, noise impacts resulting from construction and installation of the onshore facilities would be temporary **negligible** adverse.<br>Most activities would generally not be conducted during the active bat foraging period between twilight and sunrise, thus noise from maintenance | **Onshore**: Alternatives C through F would not alter onshore activities. Therefore, impacts would be the same as the Proposed Action: temporary to long-term **negligible** adverse. | | | | **Onshore**: Similar to Alternatives C through F, Alternative G would not alter onshore activities, and impacts would be the same as the Proposed Action: temporary to long term **negligible** adverse. |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action)<br>up to 100 WTGs | Alternative C<br>(Habitat Alternative)<br>64–65 WTGs | Alternative D<br>(Transit Alternative)<br>78–93 WTGs | Alternative E<br>(Viewshed Alternative)<br>64–81 WTGs | Alternative F<br>(Higher Capacity Turbine Alternative)<br>56 WTGs | Alternative G<br>(Preferred Alternative)<br>65 WTGs |
|---|---|---|---|---|---|---|---|
| | | activities is not expected to impact bat foraging behavior. Noise and traffic resulting from operation of the onshore facilities would be temporary and **negligible** adverse. Impacts to bats from noise during decommissioning would be similar to that described for construction activities.<br>Construction noise and activities associated with construction and operation of the onshore facilities could add to baseline noise and activity associated with other onshore projects with overlapping construction periods. Normal operation of the OnSS would generate continuous noise, but BOEM expects long-term **negligible** adverse associated impacts when considered in the context of the other commercial and industrial noises nearby. | | | | | |
| Presence of structures | Some habitat conversion may result from port expansion activities required to meet the demands for fabrication, construction, transportation, and installation of wind energy structures. However, the noticeable increase from future offshore wind development would be a minimal contribution in the port expansion required to meet increased commercial, industrial, and recreational demand (BOEM 2019).<br>Cave bats rarely occur offshore and given the rarity of tree bats in the offshore environment, the likelihood of exposure of cave and tree bats to construction vessels during construction or maintenance activities, or the RSZ of operating WTGs in the lease areas, is very low. Therefore, related impacts are expected to be **negligible** adverse. | **Offshore**: Exposure to vessels and installation infrastructure would be temporally limited to the construction period. Behavioral vulnerability to collision with construction equipment is expected to be **negligible** adverse.<br>Collisions between bats and OSSs could cause injury and/or mortality. However, in general, these objects would not pose a collision risk because of a bat's ability to echolocate and detect stationary structures (Stantec 2018). Bat activity can be expected to be low during WTG operation and limited to warmer periods in the summer or during fall migration. Thus, the risk of injury and/or mortality to bats would be **negligible** to **minor** adverse. The structures associated with the Proposed Action, and the consequential **negligible** to **minor** adverse impacts, would remain at least until decommissioning of the Project is complete.<br>The Project's contribution to impacts on bats would be limited because migrating bats rarely use the OCS and the Project would account for less than 4% of the total future structures on the OCS. Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in long-term **negligible** to **minor** adverse cumulative impacts to bats. | **Offshore**: Alternatives C through F would reduce the number of WTGs, potentially resulting in a reduced amount of offshore construction equipment and vessels required. However, because bat exposure to vessels and installation infrastructure would be temporally limited to the construction period, the behavioral vulnerability to collision with construction equipment under Alternatives C through F is expected to be the same as described for the Proposed Action: short term **negligible** adverse.<br>During operation, Alternatives C through F would reduce the number of WTGs as compared to the Proposed Action and potentially allow for improved maneuverability for bats through the Lease Area and negligibly decreases the risk of injury or mortality from collision with WTGs. However, impacts to bats from the presence of structures under these alternatives would not be substantially reduced and would likely be the same as the Proposed Action: long term **negligible** to **minor** adverse.<br>Alternatives C through F would add 56 to 93, additional WTGs and up to two OSSs to the No Action Alternative. Therefore, the total cumulative structures would be 3,146 to 3,183. Impacts to migration patterns or collision risk from these additional turbines would persist until decommissioning is complete. However, the Project's contribution to impacts on bats would be limited because migrating bats rarely use the OCS and the Project would account for less than 4% of the total future structures on the OCS. Therefore, these alternatives, when combined with past, present, and reasonably foreseeable projects would result in long-term **negligible** to **minor** adverse cumulative impacts to bats. | | | | **Offshore**: Similar to Alternatives C through F, construction impacts for Alternative G would be expected to be the same as described for the Proposed Action: short term **negligible** adverse.<br>During operation, similar to Alternatives C through F, Alternative G impacts to bats from the presence of structures would likely be the same as the Proposed Action: long term **negligible** to **minor** adverse.<br>Alternative G would add 65 WTGs and up to two OSSs to the No Action Alternative. Therefore, the total cumulative structures would be 3,155. Impacts to migration patterns or collision risk from these additional turbines would persist until decommissioning is complete. However, the Project's contribution to impacts on bats would be limited because migrating bats rarely use the OCS and the Project would account for less than 3% of the total future structures on the OCS. Therefore, this alternative when combined with past, present, and reasonably foreseeable projects would result in long-term **negligible** to **minor** adverse cumulative impacts to bats. |
| | | **Onshore**: Impacts on mortality and injury from the onshore construction operations would be avoided by observing time-of-year restrictions on vegetation removal that would avoid the breeding season of bats (see Appendix F, Table F-2). | **Onshore**: Alternatives C through F would not alter onshore activities. Therefore, impacts would be the same as the Proposed Action: temporary to long-term **negligible** adverse. | | | | **Onshore**: Similar to Alternatives C through F, Alternative G would not alter onshore activities, and impacts would be the same as |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTGs | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
|---|---|---|---|---|---|---|---|
| | | Therefore, these temporary impacts, if any, from construction equipment and ongoing activity would be **negligible** adverse.<br>The OnSS and ICF would be visible structures that would result in permanent bat habitat conversion and loss. Land disturbance as it relates to vegetation clearing may result in the direct injury or mortality of bats. However, mortality and injury risk would be reduced by observing time-of-year restrictions on vegetation removal to avoid bats' breeding season. Collisions between bats and onshore facilities could cause mortality. However, in general, these objects would likely not pose a collision risk because of a bat's ability to echolocate and detect stationary structures (Stantec 2018). Therefore, the impacts to bats from the presence of onshore facilities would be long term **negligible** adverse**.**<br>The contribution of the Proposed Action to cumulative impacts would not result in population-level effects given the limited amount of habitat removal and the presence of high-quality habitat in the vicinity. The combined impacts on bats from habitat loss would likely be long term **negligible** adverse given the limited amount of habitat removal and the presence of high-quality habitat in the vicinity. | | | | | the Proposed Action: temporary to long term **negligible** adverse. |

### 3.5.2.2 Alternative A: Impacts of the No Action Alternative on Bats

#### 3.5.2.2.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for bats (see Section 3.5.1) would continue to follow current regional trends and respond to IPFs introduced by other ongoing activities and by permitted and constructed offshore wind COP projects within the GAA for bats. These IPFs are described and analyzed in Appendix E1.

#### 3.5.2.2.2 Cumulative Impacts

This section discloses potential bat impacts associated with future offshore wind development (without the Proposed Action). The cumulative impact analysis for the No Action Alternative for planned non–offshore wind activities, as well as activities associated with constructed or approved offshore wind projects (without the Proposed Action), is provided in Appendix E1.

Cable emplacement/maintenance: A small amount of infrequent construction impacts associated with onshore power infrastructure would be required over the next 6 to 10 years to tie future offshore wind energy projects to the electric grid. Typically, this would require only small amounts of habitat removal, if any, and would occur in previously disturbed areas. Temporary to short-term impacts associated with habitat loss or avoidance during cable emplacement/maintenance may occur, but no injury or mortality of bat individuals would be expected. Cable emplacement/maintenance is therefore expected to have **negligible** adverse impacts on bats.

Light: Lighting sources on the WTGs and OSSs may serve as an attractant to bats as they navigate, or bats may be indirectly attracted to insect prey drawn to the lights. The lack of bat carcasses reported during large-scale bird-related fatality events at illuminated lighthouses, lightships, and oil or research platforms indicates that bats do not appear to be as susceptible to these types of collision risks as some birds (Stantec 2018). The wind turbines would be lit with aviation lighting, although the duration of lighting would be minimized by an automatic detection lighting system (ADLS) (see Table F-2 in Appendix F for details). Aviation lighting has not been found to influence bat collision risk at onshore facilities in North America (Arnett et al. 2008). Based on collision mortalities documented at onshore wind farms, the behavioral vulnerability to collision due to offshore lighting for all bat species would be **negligible** adverse.

Noise: Anthropogenic noise on the OCS associated with future offshore wind development, including noise from pile-driving and construction activities (e.g., use of noise-producing heavy equipment or machinery), could impact bats on the OCS. Noise from pile driving would occur during installation of foundations for offshore structures at a frequency of 4 to 6 hours at a time over 6 to 10 years. Construction activity would be temporary to short term, and highly localized. Further, the majority of these activities would take place during the day while bats are in torpor. A study evaluated the effect of noise on torpid bats and found that bats responded most strongly to colony and vegetation noise and most weakly to traffic noise (Luo et al. 2014). The study also documented evidence that torpid bats can rapidly habituate to repeated and prolonged noise disturbance, suggesting that traffic noise is less disturbing to torpid bats than colony or vegetation noise (Luo et al. 2014). Another study found that bats avoided foraging areas subjected to strong noise impacts (Schaub et al. 2008). This study suggests that foraging areas close to highways and other sources of intense broadband noises are degraded in their suitability as foraging areas for "passive listening" bats (Schaub et al. 2008). Because most construction activities would generally not be conducted during the active bat foraging period between twilight and sunrise, most noise generated from construction activities is not expected to impact bat foraging behavior. Luo et al. (2014) demonstrated that bat response to traffic noise was low relative to other stimuli (e.g., colony noise, vegetation) and that bats rapidly habituate to prolonged noise disturbance. Auditory impacts are not expected to occur because recent research shows that bats may be less sensitive to temporary threshold shifts than other terrestrial mammals (Simmons et al. 2016). Construction activities could generate noise sufficient to cause avoidance behavior by individual migrating tree bats (Schaub et al. 2008), thus potentially causing habitat-related impacts (i.e., displacement). These impacts would likely be limited to behavioral avoidance of pile-driving and/or construction activities (e.g., use of noise-producing heavy equipment or machinery), and no temporary or permanent hearing loss would be expected (Simmons et al. 2016). However, these impacts are unlikely because little use of the OCS is expected by bats, and only during spring and fall migrations. Therefore, based on available information, noise impacts resulting from construction of offshore facilities would be temporary **negligible** adverse.

Some potential for temporary to short-term and localized habitat impacts arising from onshore construction noise exists; however, no auditory impacts on bats would be expected. As discussed with offshore construction noise, recent literature suggests that bats are less susceptible to temporary or permanent hearing loss from exposure to intense sounds (Simmons et al. 2016). Impacts would be limited to individuals roosting adjacent to onshore construction locations. Nighttime work may be required on an as-needed basis, which could impact foraging bats. Some temporary displacement and/or avoidance of potentially suitable foraging habitat could occur, but these impacts would not be biologically significant. Some bats roosting near construction activities may be disturbed during construction, but they would move to a different roost farther from construction noise. This would not result in any impacts because frequent roost switching is common among bats (Hann et al. 2017; Whitaker 1998). Based on available information, noise impacts resulting from construction of the onshore facilities would be temporary **negligible** adverse.

Nonroutine activities associated with offshore wind facilities would generally require intense temporary activity to address emergency conditions. The noise made by onshore construction equipment or offshore repair vessels could temporarily deter bats from approaching the site of a given nonroutine event. Impacts on bats, if any, would be temporary and last only as long as repair or remediation activities were necessary to address these nonroutine events.

Given the temporary and localized nature of potential impacts and bats' expected biologically insignificant response, impacts on bats are expected to be **negligible** adverse. No individual fitness (i.e., a bat's ability to survive and reproduce) or population-level impacts would occur as a result of onshore or offshore noise associated with future offshore wind development.

<u>Presence of structures:</u> In addition to electrical infrastructure, some habitat conversion may result from port expansion activities required to meet the demands for fabrication, construction, transportation, and installation of wind energy structures. The general trend along the coastal region from Virginia to Maine is that port activity will increase modestly and require some conversion of undeveloped land to meet port demand and will result in permanent habitat loss for local bat populations. However, the noticeable increase from future offshore wind development would be a minimal contribution in the port expansion required to meet increased commercial, industrial, and recreational demand (BOEM 2019). The current

bearing capacity of existing ports is considered suitable for wind turbines, requiring no port modifications for supporting offshore wind energy development (U.S. Department of Energy [2014]).

Using the assumptions in Table E-4 in Appendix E, the cumulative offshore wind activities scenario would include up to 3,025 WTGs on the OCS that could result in potential impacts on bats. Cave bats (including the federally threatened northern long-eared bat and the state-endangered eastern small-footed bat, little brown bat, and tri-colored bat) rarely occur offshore (even during fall migration) and, therefore, exposure to construction vessels during construction or maintenance activities, or the rotor swept zone (RSZ) of operating WTGs in the lease areas, is expected to be **negligible** adverse, if exposure occurs at all (Pelletier et al. 2013).

Tree bats, however, may pass through offshore WEAs on the OCS during the fall migration, with limited potential for migrating bats to encounter vessels during construction and decommissioning of WTGs, electric service platforms, and offshore export cable corridors, although structure and vessel lights may attract bats because of the increased prey abundance. As discussed above, although bats have been documented at offshore islands, relatively little bat activity has been documented in open water habitat similar to the conditions in the WEAs (Stantec 2018, 2020). Several studies, such as Cryan and Barclay (2009), Cryan et al. (2014), and Kunz et al. (2007), discuss several hypotheses as to why bats may be attracted to WTGs. Many of these, including the creation of linear corridors, altered habitat conditions, or thermal inversions, would not apply to WTGs on the Atlantic OCS (Cryan and Barclay 2009; Cryan et al. 2014; Kunz et al. 2007). Other hypotheses associated with the Atlantic OCS regarding bat attraction to WTGs include bats perceiving the WTGs as potential roosts, potentially increased prey base, visual attraction, disorientation due to electromagnetic fields or decompression, or attraction due to mating strategies (Arnett et al. 2008; Cryan et al. 2007; Kunz et al. 2007). However, no definitive answer as to why, if at all, bats are attracted to WTGs has been postulated, despite intensive studies at onshore wind facilities. For this reason, some bats may encounter, or perhaps be attracted to, the expected structures (i.e., electric service platforms and non-operational WTG towers) to opportunistically roost or forage. However, bats’ echolocation abilities and agility make it unlikely that these stationary objects (i.e., electric service platforms and non-operational WTGs) or moving vessels would pose a collision risk to migrating individuals. This assumption is supported by the evidence that bat carcasses are rarely found at the base of onshore turbine towers (Choi et al. 2020).

Tree bat species that may encounter operating WTGs in the offshore lease areas include the eastern red bat, the hoary bat, and the silver-haired bat. Offshore O&M would present a seasonal risk factor to migratory tree bats that may use offshore habitats during fall migration. Although some potential exists for migrating tree bats to encounter operating WTGs during fall migration, the overall occurrence of bats on the OCS is relatively very low (Stantec 2016). With the proposed 1-nm (1.9-km) spacing between structures associated with future offshore wind development and the distribution of anticipated projects, individual bats migrating over the OCS within the RSZ of project WTGs would likely pass through projects with only slight course corrections, if any, to avoid operating WTGs. Further, unlike terrestrial migration routes there are no landscape features that would concentrate bats and increase exposure to the WEAs on the OCS (Baerwald and Barclay 2009; Cryan and Barclay 2009; Fiedler 2004; Hamilton 2012; Smith and McWilliams 2016). This combined with the expected infrequent and limited use of the OCS by migrating tree bats suggests very few individuals would encounter operating WTGs or other structures associated with future offshore wind development. Additionally, the potential collision risk to migrating tree bats varies with climatic conditions. For example, bat activity is associated with relatively low wind speeds and warm temperatures (Arnett et al. 2008; Cryan and Brown 2007; Fiedler 2004; Kerns et al. 2005). Given the rarity of tree bats in the offshore environment, the turbines being widely spaced apart, and the patchiness of expected projects on the OCS, the likelihood of collisions is expected to be low. Additionally, the likelihood of a migrating individual encountering one or more operating WTGs during adverse weather conditions is extremely low because bats have been shown to suppress activity during periods of strong winds, low temperatures, and rain (Arnett et al. 2008; Erickson et al. 2002).

For these reasons, the likelihood of exposure of tree bats to construction vessels during construction or maintenance activities, or the RSZ of operating WTGs in the lease areas, is very low, and therefore related impacts are expected to be **negligible** adverse.

#### 3.5.2.2.3 Conclusions

Under the No Action Alternative, the Project would not be built. Impacts from ongoing future non–offshore and offshore wind development activities would still occur. BOEM expects ongoing activities, future non–offshore wind development, and future offshore wind development to have continuing temporary to permanent impacts (e.g., disturbance, displacement, injury, mortality, and habitat conversion) on bats primarily through the onshore construction impacts, the presence of structures, and climate change. BOEM anticipates that the potential impacts of ongoing activities would be **negligible** adverse. In addition to ongoing activities, BOEM anticipates that the impacts of planned actions other than offshore wind development may also contribute to impacts on bats, including increasing onshore construction (see Appendix E1), but that these impacts would be **negligible** adverse. BOEM expects the combination of ongoing and planned actions other than offshore wind development to result in **negligible** adverse impacts on bats. Although the impacts from a substitute project may differ in location and time, depending on where and when offshore wind facilities are developed to meet the remaining demand, the nature of impacts and the total number of WTGs would be similar either with or without the Proposed Action. The No Action Alternative would forgo applicant-committed postconstruction acoustic monitoring for bats and annual mortality reporting. Their results could provide an understanding of the effects of offshore wind development, benefit the future management of these species, and inform planning of other offshore development. However, ongoing and future surveys and monitoring could still supply similar data.

Considering all the IPFs together, BOEM anticipates that the overall impacts associated with future offshore wind activities in the GAA would result in **negligible** adverse impacts from ongoing climate change, lighting, interactions with operating WTGs on the OCS, and onshore habitat loss. Given the infrequent and limited anticipated use of the OCS by migrating tree bats during spring and fall migration, as well as cave bats not typically occurring on the OCS, the IPFs associated with future offshore wind activities that occur offshore would not appreciably contribute to overall impacts on bats. Future offshore wind development could result in some potential for temporary disturbance and permanent loss of onshore bat habitat. However, habitat removal is anticipated to be minimal when compared to other past, present, and reasonably foreseeable activities. Any impacts resulting from habitat loss or disturbance would not be expected to result in individual fitness or population-level effects within the GAA.

### 3.5.2.3 Alternative B: Impacts of the Proposed Action Alternative on Bats

#### 3.5.2.3.1 Construction and Installation

##### Offshore Activities and Facilities

Light: Bats may demonstrate attraction to or avoidance of construction vessels installing offshore facilities, particularly if insects (i.e., prey) are drawn to the lights of the vessels (BOEM 2014). Exposure to vessels and installation infrastructure would be temporally limited to the construction period. Thus, behavioral changes due to lighting on construction vessels would be temporary, and impacts to bats would be **negligible** adverse, with long-distance migratory bats most at risk because they are most likely to seasonally occur in the airspace of the RWF.

Noise: Pile-driving noise and offshore construction noise associated with the Proposed Action would be temporary to short term and highly localized and is expected to result in **negligible** adverse impacts. Auditory impacts are not expected to occur as recent research shows that bats may be less sensitive to temporary threshold shifts than other terrestrial mammals (Simmons et al. 2016). Impacts, if any, would be limited to behavioral avoidance of pile-driving and/or construction activities, and no temporary or permanent hearing loss would be expected (Simmons et al. 2016).

Presence of structures: Bats are expected to seasonally occur in the Lease Area while migrating, commuting, or foraging. Bats were observed roosting aboard support vessels during the construction of the Block Island Wind Farm (Stantec 2016), suggesting the presence of artificial roosting structures may provide some benefit to bats in the offshore environment. Bats are well known for their ability to detect objects with echolocation (Horn et al. 2008; Johnson et al. 2004) and thus are unlikely to collide with stationary structures (Cryan 2011). Further, exposure to vessels and installation infrastructure would be temporally limited to the construction period. Behavioral vulnerability to collision with construction equipment is expected to be **negligible** adverse.

##### Onshore Activities and Facilities

Cable emplacement/maintenance: The preferred transmission cable route is an approximately 1-mile (1.6-km) route, that would predominantly follow along paved roads or previously disturbed areas such as parking lots that do not provide high-quality habitat for bats. However, some of the alternative routes under consideration within the transmission cable envelope contain segments that would pass through undeveloped, vegetated areas composed of upland forest and shrubland and would be approximately the same length (see Section 3.8). Impacts associated with construction of the onshore transmission cable could occur if construction activities take place during the active season for bats (generally April through October). Such activities may result in injury or mortality of individual bats, particularly juveniles as they are unable to flush from a roost if occupied by bats at the time of removal. However, tree and shrub removal would occur outside the bat roosting period (from May 1 through August 15) when feasible (see COP Table ES-1), thus limiting the potential for direct injury or mortality from the removal of occupied roost trees. There would be some potential for adverse impacts on bats as a result of the loss of potentially suitable roosting and/or foraging habitat, but these impacts would be **negligible** adverse.

BOEM anticipates that **negligible** adverse impacts, if any, would occur with adherence to USFWS northern long-eared bat conservation measures and that **negligible** adverse habitat impacts would not result in individual fitness or population-level effects given the limited amount of habitat removal and the presence of high-quality bat habitat in the vicinity. Based on Project timing, the limited area of effect relative to available habitat, and the proposed impact avoidance and minimization measures, adverse impacts of the Proposed Action on northern long-eared bat would be **negligible** adverse. A detailed impacts analysis to northern long-eared bats from Project construction activities is provided in the USFWS BA (BOEM 2022, 2023).

Light: Some overnight lighting would occur during construction of the onshore facilities. Wildlife typically not exposed to light, such as bats, may behave differently if exposed to light at nighttime. Because most construction activities would occur during the day over the approximately 1-year construction period for the onshore facilities, impacts from lighting on bats would be **negligible** adverse.

Noise: Some potential for temporary to short term and localized habitat impacts arising from onshore construction noise exists; however, no auditory impacts on bats would be expected. As discussed with offshore construction noise, recent literature suggests that bats are less susceptible to temporary or permanent hearing loss from exposure to intense sounds (Simmons et al. 2016). Based on available information discussed in Section 3.5.1.1, noise impacts resulting from construction and installation of the onshore facilities would be temporary **negligible** adverse.

Presence of structures: Visible structures (i.e., construction equipment) would be present during construction of the onshore facilities. Collisions between bats and vehicles or construction equipment could cause injury and/or mortality. However, in general, these objects would not pose a collision risk because of a bat's ability to echolocate and detect stationary structures (Stantec 2018). The operational footprints of the OnSS and ICF would result in habitat loss when forested upland is cleared and replaced with hard structures and crushed gravel yards. The ICF would result in a loss of approximately 1.6 acres (0.6 ha) of mixed oak/white pine forest, which is reflective of the operational footprint of the ICF. The OnSS would create a loss of 3.8 acres (1.5 ha) of mixed oak/white pine forest and 0.6 acre (0.2 ha) of ruderal pitch pine barren. Together, these losses represent a relatively small fraction of the 52 acres (21 ha) of contiguous bat habitat identified in the *Rhode Island Wildlife Action Plan* (RIWAP) (Rhode Island DEM et al. 2015). Impacts on mortality and injury from the onshore construction operations would be avoided by observing time-of-year restrictions on vegetation removal that would avoid the breeding season of bats (see COP Table ES-1). Therefore, these temporary impacts, if any, from construction equipment and ongoing activity would be **negligible** adverse.

#### 3.5.2.3.2 Operations and Maintenance and Decommissioning

### Offshore Activities and Facilities

Light: Lighting sources on the WTGs and OSSs may serve as an attractant to bats as they navigate, or bats may be indirectly attracted to insect prey drawn to the lights. However, bats do not appear to be as susceptible to these types of collision risks as some birds (Stantec 2018), and aviation lighting has not been found to influence bat collision risk at onshore facilities in North America (Arnett et al. 2008). Lighting during the O&M phase of the Project would be limited, which should reduce insect and potential bat attraction (Stantec 2018). Revolution Wind would comply with FAA (2018) and BOEM (2021c) requirements for lighting while using lighting technology (e.g., low-intensity strobe lights) that minimize impacts on bat species. Overall, collision-related mortality or injury from lighting at the offshore facilities could result in **negligible** to **minor** adverse impacts to bats at the RWF, with long-distance migratory bats most at risk because they are most likely to seasonally occur in the airspace of the RWF.

Noise: Boat activity and noise already occur within and adjacent to the Lease Area based on existing levels of vessel traffic, as described in Section 3.16. Increases in activity and associated disturbances during RWF maintenance activities would have a short-term **negligible** adverse impact on bats because of the limited additional vessel activity and relatively low likelihood of bat occurrence near the RWF. There would also be no impacts to bats during O&M of the offshore RWEC because these components are underwater, and there would be no routine maintenance at these components.

Presence of structures: During Project O&M, injury or mortality from collision with WTGs represents the greatest potential risk to bats. WTGs and other offshore facilities may also provide roosting opportunities for bats. Collisions between bats and OSSs could cause injury and/or mortality. However, in general, these objects would not pose a collision risk because of a bat's ability to echolocate and detect stationary structures (Stantec 2018). Additionally, individual bats could collide with WTGs, resulting in mortality or injury. It is difficult to confirm bat fatalities at offshore WTGs; however, offshore bat occurrences are relatively infrequent and primarily seasonal (during migration), and activity declines as the distance from shore increases. Existing data from meteorological buoys provide the best opportunity to further define bat use of open-water habitat far from shore where Project WTGs are proposed. Relatively few bat passes were detected at meteorological buoy sites, and use was sporadic when compared to sites on offshore islands (Stantec 2016). In general, the bat species assessed are not expected to regularly forage in the Lease Area, but some may be present during migration, particularly in the fall (BOEM 2012; Stantec 2018).

Specific weather conditions may contribute to bat mortality from turbines. Mortality data from onshore wind farms indicate that bat collision mortality is expected to occur mainly on nights with calm winds during migratory periods as relatively more bats are migrating at greater altitudes in favorable conditions (Arnett et al. 2008). Likewise, coastal and offshore acoustic studies (Stantec 2016) found that greater wind speeds and cool temperatures have an adverse effect on bat activity. However, during fall migration, bats may take advantage of favorable wind directions and may be more likely to fly during colder weather (Stantec 2016). Most offshore bat activity took place at wind speeds less than 5 m/s. Because average wind speeds in the Lease Area are between 5 and 10 m/s, with stronger wind in the winter, bat activity can be expected to be low during WTG operation and limited to warmer periods in the summer or during fall migration. Thus, the risk of injury and/or mortality to bats would be **negligible** to **minor** adverse. The structures associated with the Proposed Action, and the consequential **negligible** to **minor** adverse impacts, would remain at least until decommissioning of the Project is complete. Impacts from O&M of the RWF to the listed northern long-eared bat are not expected because of their low collision risk and the rarity of their occurrence offshore. A detailed impacts analysis to northern long-eared bats from Project operation and decommissioning is provided in the USFWS BA (BOEM 2022, 2023).

### Onshore Activities and Facilities

Cable emplacement/maintenance: Hazard tree removal would be performed on a cyclical basis to inspect and remove trees that may fall that are outside the edge of the maintained ROW. However, mortality and injury risk would be reduced by observing time-of-year restrictions on vegetation removal to avoid bats' breeding season. Therefore, the impacts resulting from vegetation clearing would be **negligible** adverse. Impacts from land disturbance during decommissioning would be similar to those described within the construction impact analysis, although the impacts would likely be less because new vegetation clearing and grading would not be necessary.

Light: During the O&M of the OnSS and ICF, general yard lighting would be used for assessment of equipment. In general, lighting would be off at night unless there is work in progress or lights are left on for safety and security purposes. Insect prey could be drawn in by lighting at the OnSS and ICF and thus attract foraging bats. However, the surrounding area is currently developed, and lighting-related effects would be abated using minimum-intensity and motion-activated lighting and shielding and downward angling light sources where practicable. As during construction of the onshore facilities, lighting at night has the potential to temporarily displace bats and/or disrupt normal behavior. Because the use of lighting at night is expected to be infrequent, the impacts it has on temporary bat displacement and/or behavior disruption would be **negligible** adverse.

Noise: According to VHB's onshore acoustic assessment (VHB 2023a), during O&M, the proposed OnSS and ICF would introduce new sources of sound, which are modeled to be 45.5 A-weighted decibels (dBA) equivalent sound level (Leq) or less when measured at the nearest anthropogenic sensitive receptors and fall within the ambient sound range measured at baseline conditions. Temporary noise and construction-related traffic may occasionally be generated due to nonroutine maintenance. Pickup trucks may be used to make routine visits to the OnSS and ICF during O&M. Occasional O&M emergency visits may necessitate bucket trucks, cranes, and similar vehicles. Infrequent vehicle usage within the OnSS and ICF may create temporary noise-related disturbance to bats adjacent to the OnSS. However, most activities would generally not be conducted during the active bat foraging period between twilight and sunrise, thus noise from maintenance activities is not expected to impact bat foraging behavior. Luo et al. (2014) demonstrated that bat response to traffic noise was low relative to other stimuli (e.g., colony noise, vegetation) and that bats rapidly habituate to prolonged noise disturbance. Based on this available information, noise and traffic resulting from operation of the onshore facilities would be temporary and **negligible** adverse. Impacts to bats from noise during decommissioning would be similar to that described for construction activities.

Presence of structures: The OnSS and ICF would be visible structures that would result in permanent bat habitat conversion and loss. Land disturbance in the form of vegetation management would occur on a periodic basis to maintain vegetation at shrub height within the operational footprint of the onshore facilities. Land disturbance as it relates to vegetation clearing may result in the direct injury or mortality of bats. However, mortality and injury risk would be reduced by observing time-of-year restrictions on vegetation removal to avoid bats' breeding season. Collisions between bats and onshore facilities could cause mortality. However, in general, these objects would likely not pose a collision risk because of a bat's ability to echolocate and detect stationary structures (Stantec 2018). Therefore, the impacts to bats from the presence of onshore facilities would be long term **negligible** adverse**.**

#### 3.5.2.3.3 Cumulative Impacts

### Offshore Activities and Facilities

Lighting: The Proposed Action would add up to 100 new WTGs with red flashing aviation hazard lighting to the offshore environment. Additionally, marine navigation lighting would include multiple flashing white lights on each WTG and the OSSs and would be directed out and down to the water surface. Vessel lights during construction and installation, O&M, and decommissioning would be minimal and limited to vessels transiting to and from construction areas. These lights could serve as an attractant to bats as they navigate, or bats may be indirectly attracted to insect prey drawn to the lights.

However, the lack of bat carcasses reported during large-scale bird-related fatality events at illuminated lighthouses, lightships, and oil or research platforms indicates that bats do not appear to be as susceptible to these types of collision risks as some birds (Stantec 2018). As such, ongoing and future non–offshore wind activities are expected to cause permanent impacts, primarily driven by light from offshore structures and short-term and localized impacts from vessel lights. For these reasons, the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in long-term **negligible** to **minor** adverse cumulative impacts to bats, with long-distance migratory bats most at risk because they are most likely to seasonally occur in the Lease Area.

<u>Noise:</u> Pile-driving and other construction noise and activity associated with the Proposed Action would add to baseline noise and activity associated with other offshore wind projects with overlapping construction periods. However, the Proposed Action's contribution to noise impacts would be limited in duration and cease when construction ends. Therefore, the cumulative impact of the Proposed Action when combined with other past, present, and reasonably foreseeable projects would result in short-term **negligible** to **minor** adverse impacts to bats.

<u>Presence of structures:</u> The Proposed Action would add up to 100 additional WTGs and up to two OSSs to the No Action Alternative. Therefore, the total cumulative structures would be 3,190. Impacts to migration patterns or collision risk from these additional turbines would persist until decommissioning is complete. However, the Project's contribution to impacts on bats would be limited because migrating bats rarely use the OCS and the Project would account for less than 4% of the total future structures on the OCS. Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in long-term **negligible** to **minor** adverse cumulative impacts to bats.

### Onshore Activities and Facilities

<u>Cable emplacement/maintenance:</u> The transmission cable envelope contains approximately 0.56 acre (0.22 ha) of mixed oak/white pine forest, 0.32 acre of softwood forest, 0.02 acre of ruderal grassland/shrubland, 0.008 acre of oak forest, and 0.006 acre of pitch pine barren (see Section 3.8). Onshore construction and installation would add to other limited onshore bat habitat disturbance actions. Land disturbance associated with cable emplacement could result in the loss of potentially suitable roosting and/or foraging habitat for bats. However, the preferred transmission cable route is an approximate 1-mile (1.6-km) route that would predominantly follow along paved roads or previously disturbed areas such as parking lots. Further, Revolution Wind and other future land developers would adhere to USFWS northern long-eared bat conservation measures. As a result, cumulative impacts would not result in population-level effects given the limited amount of habitat removal and the presence of high-quality habitat in the vicinity. Therefore, the cumulative impact of the Proposed Action when combined with past, present, and reasonably foreseeable projects would result in short-term **negligible** to **minor** adverse impacts to bats.

<u>Light:</u> The Proposed Action would involve the use of some overnight lighting during construction and installation and during O&M and decommissioning of the onshore facilities. O&M lighting of facilities would be switch activated and would only occur when O&M activities are ongoing. Lighting from construction and operations could add to baseline light sources and activities associated with other onshore projects. Because the use of lighting at night is expected to be infrequent, the impacts it has on temporary bat displacement and/or behavior would be short term **negligible** adverse. When considered in

the context of the other nearby commercial and industrial lighting within the GAA, BOEM expects **negligible** adverse cumulative impacts to bats.

Noise: Construction noise and activities associated with construction and operation of the onshore facilities could add to baseline noise and activity associated with other onshore projects with overlapping construction periods. However, the Proposed Action's incremental contribution would be **negligible** adverse as it would be limited in duration and cease when construction ends. No individual fitness or population-level effects would be expected. Normal operation of the OnSS would generate continuous noise, but BOEM expects long-term **negligible** adverse associated impacts when considered in the context of the other commercial and industrial noises nearby.

Presence of structures: Onshore construction and installation would add to other limited onshore bat habitat disturbance actions through the removal of approximately 1.6 acres (0.6 ha) of mixed oak/white pine forest at the ICF. The OnSS would create a loss of 3.8 acres (1.5 ha) of mixed oak/white pine forest. This land disturbance could result in the loss of potentially suitable roosting and/or foraging habitat for bats. However, Revolution Wind and other future land developers would adhere to USFWS northern long-eared bat conservation measures, which would also minimize impacts to other roosting/foraging bat species. As a result, the contribution of the Proposed Action to cumulative impacts would not result in population-level effects given the limited amount of habitat removal and the presence of high-quality habitat in the vicinity. The combined impacts on bats from habitat loss would likely be long term **negligible** adverse given the limited amount of habitat removal and the presence of high-quality habitat in the vicinity. Collisions between bats and structures have some limited potential to cause mortality. However, in general, these objects would not pose a collision risk because of a bat's ability to echolocate and detect stationary structures and therefore would not contribute to cumulative impacts to bats.

#### 3.5.2.3.4 Conclusions

In summary, construction and installation, O&M, and decommissioning of the Proposed Action would have **negligible** to **minor** adverse impacts on bats, especially if conducted outside the active season. The main significant risk would be from operation of the offshore WTGs, which could lead to long-term **negligible to minor** adverse impacts in the form of collision-related mortality, although BOEM anticipates this to be rare. In the context of reasonably foreseeable environmental trends in the area, impacts of individual IPFs resulting from ongoing and planned actions, including the Proposed Action, would be **negligible** to **minor** adverse. Considering all the IPFs together, BOEM anticipates that the impacts from ongoing and planned actions, including the Proposed Action, would result in **negligible** to **minor** adverse impacts on bats in the GAA because of ongoing climate change, interactions with operating WTGs on the OCS, and onshore habitat loss. Future offshore wind activities are not expected to materially contribute to the IPFs discussed above. Given the infrequent and limited anticipated use of the OCS by migrating tree bats during spring and fall migration and that cave bats do not typically occur on the OCS, the IPFs associated with future offshore wind activities that occur offshore would not be expected to appreciably contribute to overall impacts on bats. Some potential for temporary disturbance and permanent loss of onshore habitat may occur as a result of future offshore wind development. However, habitat removal is anticipated to be minimal, and any impacts resulting from habitat loss or disturbance would not be expected to result in individual fitness or population-level effects within the GAA. The Proposed Action would contribute to the overall impact rating primarily through the permanent impacts due to onshore habitat loss. Thus, the overall impacts on bats would be **minor** adverse because limited impacts are expected due to the minimal presence of bats within the Lease Area and bat populations would recover completely.

### 3.5.2.4 Alternatives C, D, E, and F

Table 3.5-1 provides a summary of IPF findings for these alternatives.

#### 3.5.2.4.1 Conclusions

Alternatives C through F would reduce the number of WTGs, which subsequentially would reduce the potential collision risk for bats. Still, BOEM expects the overall impacts of these alternatives to bats would be similar to the Proposed Action: **negligible** to **minor** adverse.

In the context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that Alternatives C through F's contribution to the cumulative impacts would be similar to the Proposed Action (ranging from **negligible** to **minor** adverse, depending on the IPF). The overall impacts of Alternatives C through F when combined with past, present, and reasonably foreseeable activities would therefore be the same as under the Proposed Action: **minor** adverse.

### 3.5.2.5 Alternative G: Impacts of the Preferred Alternative on Bats

Table 3.5-1 provides a summary of IPF findings for this alternative.

#### 3.5.2.5.1 Conclusions

Although Alternative G would reduce the number of WTGs, the presence of WTGs could still increase the potential for collision, albeit at lower levels than the Proposed Action. Still, BOEM expects the overall impacts of these alternatives to bats would be similar to the Proposed Action: **negligible** to **minor** adverse.

In the context of other reasonably foreseeable environmental trends and planned actions, BOEM also expects that Alternative G's contribution to cumulative impacts would be similar to the Proposed Action (ranging from **negligible** to **minor** adverse, depending on the IPF). The overall impacts of Alternative G when combined with past, present, and reasonably foreseeable activities would therefore be the same as under the Proposed Action: **minor** adverse.

### 3.5.2.6 Mitigation

Mitigation measures resulting from agency consultations for bats are identified in Appendix F, Table F-2, and addressed in Table 3.5-2. Draft conservation recommendations proposed to BOEM by the USFWS on May 22, 2023, are identified in Appendix F, Table F-3, and addressed in Table 3.5-3.

**Table 3.5-2. Mitigation and Monitoring Measures Resulting from Consultations for Bats (Appendix F, Table F-2)**

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| Annual bird and bat mortality reporting | Revolution Wind must submit an annual report covering each calendar year, due by January 31 of the following year, documenting any dead (or injured) birds or bats found on vessels and structures during construction, operations, and decommissioning. The report must be submitted to BOEM (at renewable_reporting@boem.gov), BSEE (at OSWSubmittals@bsee.gov), and the USFWS. The report must contain the following information: name of species, date found, location, a picture to confirm species identity (if possible), and any other relevant information. Carcasses with federal or research bands must be reported to the USGS Bird Banding Laboratory at https://www.usgs.gov/labs/bird-banding-laboratory. | This measure would not reduce impacts; however, the data gathered from the mortality reporting would be used to evaluate impacts and potentially lead to additional mitigation measures, if required (30 CFR 585.633(b)). |
| Annual bird and bat mortality reporting | Any occurrence of dead ESA birds or bats must be reported to BOEM, BSEE, and USFWS as soon as practicable (taking into account crew and vessel safety), but no later than 24 hours after the sighting, and if practicable, carefully collect the dead specimen and preserve the material in the best possible state. | This measure would not reduce impacts; however, the data gathered from the monitoring would be used to evaluate impacts and potentially lead to additional mitigation measures, if required (30 CFR 585.633(b)). |
| Annual bird and bat mortality reporting | Any occurrence of dead ESA birds or bats must be reported to BOEM, BSEE, and USFWS as soon as practicable (taking into account crew and vessel safety), but no later than 24 hours after the sighting, and if practicable, carefully collect the dead specimen and preserve the material in the best possible state. | This measure would not reduce impacts; however, the data gathered from the monitoring would be used to evaluate impacts and potentially lead to additional mitigation measures, if required (30 CFR 585.633(b)). |
| Avian and bat monitoring program | At least 45 calendar days before beginning surveys, Revolution Wind must complete, obtain concurrence from the U.S. Department of the Interior (DOI), and adopt an avian and bat monitoring plan (ABMP), as described in Revolution Wind's *Avian and Bat Post-Construction Monitoring Framework* (BRI 2022) in COP Appendix AA (BRI 2023), including coordination with interested stakeholders. The DOI will review the ABMP and provide any comments on the plan within 30 calendar days of its submittal. Revolution Wind must resolve all comments on the ABMP to the DOI's satisfaction before implementing the plan. Revolution Wind may conclude that the DOI has concurred in the ABMP | |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | if the DOI provides no comments on the plan within 30 calendar days of its submittal date.<br>a. Monitoring. Revolution Wind must 1) install acoustic monitoring devices for bats for 2 years; 2) install Motus receivers within the wind farm; 3) refurbish up to two onshore Motus receiver stations; 4) provide funding for up to 150 Motus tags per year for up to 3 consecutive years; and 5) conduct a 1- to 2-year cross project radar study to measure migrant flux rates, flight heights, and marine bird avoidance.<br>b. Annual Monitoring Reports. Revolution Wind must submit to BOEM (at renewable_reporting@boem.gov), the USFWS, and BSEE (at OSWSubmittals@bsee.gov) a comprehensive report after each full year of monitoring (preconstruction and postconstruction) within 6 months of completion of the last avian survey. The report must include all data, analyses, and summaries regarding ESA-listed and non-ESA-listed birds and bats. The DOI will use the annual monitoring reports to assess the need for reasonable revisions (based on subject matter expert analysis) to the ABMP. The DOI reserves the right to require reasonable revisions to the ABMP and may require new technologies as they become available for use in offshore environments.<br>c. Postconstruction Quarterly Progress Reports. Revolution Wind must submit quarterly progress reports during the implementation of the ABMP to BOEM (at renewable_reporting@boem.gov) and the USFWS by the fifteenth day of the month following the end of each quarter during the first full year that the Project is operational. The progress reports must include a summary of all work performed, an explanation of overall progress, and any technical problems encountered.<br>d. Monitoring Plan Revisions. Within 15 calendar days of submitting the annual monitoring report, Revolution Wind must meet with BOEM and the USFWS to discuss the following: the monitoring results; the potential need for revisions to the ABMP, including technical refinements or additional monitoring; and the potential need for any additional efforts to reduce impacts. If the DOI determines after this | |

| Mitigation Measure | Description | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | discussion that revisions to the ABMP are necessary, the DOI may require that Revolution Wind modify the ABMP. If the reported monitoring results deviate substantially from the impact analysis included in the Final EIS, Revolution Wind must transmit to the DOI recommendations for new mitigation measures and/or monitoring methods.<br>e. Operational Reporting (Operations). Revolution Wind must submit to BOEM (at renewable_reporting@boem.gov) and BSEE (at OSWSubmittals@bsee.gov) an annual report summarizing the following monthly operational data calculated from 10-minute supervisory control and data acquisition (SCADA) for all turbines together in tabular format: the proportion of time the turbines were operational (spinning at > x rpm) each month, the average rotor speed (monthly rpms) of spinning turbines plus 1 standard deviation, and the average pitch angle of blades (degrees relative to rotor plane) plus 1 standard deviation. The DOI will use this information as inputs for avian collision risk models to assess whether the results deviate substantially from the impact analysis included in the Final EIS.<br>f. Raw Data. Revolution Wind must store the raw data from all avian and bat surveys and monitoring activities according to accepted archiving practices. Such data must remain accessible to the DOI and the USFWS, upon request for the duration of the lease. Revolution Wind must work with BOEM to ensure the data are publicly available. The USFWS may specify third-party data repositories that must be used, such as the Motus Wildlife Tracking System or MoveBank, and such parties and associated data standards may change over the duration of the monitoring plan. | |
| Adaptive mitigation for birds and bats | If the reported postconstruction bird and bat monitoring results (generated as part of Revolution Wind's *Avian and Bat Post-Construction Monitoring Framework* [BRI 2022]) indicate bird and bat impacts deviate substantially from the impact analysis included in this EIS, then Revolution Wind must make recommendations for new mitigation measures or monitoring methods. | This mitigation measure, if adopted, ensures that Project activities would not impact bats beyond the negligible to minor range of impacts discussed in this EIS. |

**Table 3.5-3. Additional Mitigation and Monitoring Measures under Consideration for Bats (Appendix F, Table F-3)**

| Mitigation Measure* | Description* | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| USFWS Biological Opinion Conservation Recommendation 2: Establish an Offshore Wind Adaptive Monitoring and Impact Minimization Framework to guide and coordinate monitoring, research and avian impacts assessment coastwide. | To address Service concerns related to potential effects of WTG operation on listed and other species of concern, at both the project and coastwide scales, the USFWS recommends that the BOEM develop and adopt an Offshore Wind Adaptive Monitoring and Impact Minimization Framework (Framework) for flying wildlife. Many details will need to be worked out, but here the USFWS provides some basic principles for establishment, adoption, and operation of the Framework.<br>• Establish a Framework Principals Group to consist of representatives from the BOEM, the BSEE, the USFWS, State natural resource agencies responsible for management of birds, bats, and insect, and offshore wind energy developers/operators.<br>• Develop and adopt a written Framework foundational document specifying:<br>○ the governance structure of the Principals Group;<br>○ the geographic coverage of the Framework;<br>○ the species covered by the Framework; and<br>○ the duration of the Framework.<br>• Establish an annual operating budget for the Framework to be funded by offshore wind energy developers/operators.<br>• Arrange for the Principals Group to meet at least annually, and for the Framework foundational document to be updated at least every 5 years.<br>• Provide for experts (both internal and external to the Principals Group) to regularly assess new and improved technologies and methods for estimating collision risk of covered species and measuring or detecting collisions. Adopt and deploy such methods deemed most promising by the Principals Group. | Pursuant to 50 CFR 402.14(j), conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information. |

| Mitigation Measure* | Description* | Expected Effect on Impacts from Action Alternatives |
|---|---|---|
| | • Coordinate monitoring and research across wind energy projects. Share and pool data and research results coastwide.<br>• Provide for experts (both internal and external to the Principals Group) to regularly assess new and improved technologies and methods for minimizing collision risk of covered species. Adopt and deploy such technologies/methods deemed most promising by the Principals Group.<br>• Provide for experts (both internal and external to the Principals Group) to periodically assess new and improved technologies and methods for evaluating indirect effects to covered species from WTG avoidance behaviors (e.g., impacts to time and energy budgets).<br>• Periodically assess the level and type of compensatory mitigation necessary to offset any unavoidable direct and indirect effects of WTG operation on covered species. Adopt and require the levels and types of mitigation deemed appropriate by the Principals Group.<br>• Consider partnering with other stakeholders or cross-sector organizations to provide administrative, institutional, and technical support to the Principals Group. | |

* Information in these rows was taken directly from the final biological opinion (USFWS 2023) and has not been edited.

#### 3.5.2.6.1 Measures Incorporated into the Preferred Alternative

Mitigation measures resulting from consultations, authorizations, and permits listed in Table 3.5-2 and in Appendix F, Table F-2, are incorporated into Alternative G (Preferred Alternative). The additional measures would further define how the effectiveness and enforcement of EPMs would be ensured and improve accountability for compliance with EPMs by implementing an avian and bat monitoring program. Because these measures ensure the effectiveness of and compliance with EPMs that are already analyzed as part of the Proposed Action, implementation of these measures would not further reduce the impact level of the Proposed Action but would ensure that Project activities would not impact birds beyond the negligible to minor range of impacts discussed in this EIS and the data gathered from avian mortality reporting would be used to evaluate impacts and potentially lead to additional mitigation measures, if required (30 CFR 585.633(b)).

## 3.6 Benthic Habitat and Invertebrates (see section in main EIS)

# 3.7 Birds

## 3.7.1 Description of the Affected Environment and Environmental Consequences of the No Action Alternative for Birds

Geographic Analysis Area: The GAA for birds is the United States coastline from Maine to Florida (Figure 3.7-1). The offshore limit of the GAA is 100 miles (160.9 km) from the Atlantic Coast to capture the migratory movements of most species in this group. The onshore limit of the GAA is 0.5 mile (0.8 km) inland from the Atlantic Coast to cover onshore habitats used by the species that may be affected by offshore components of the Project as well as those species that could be affected by onshore Project components. The GAA was established to capture resident species and migratory species that winter as far south as South America and the Caribbean and those that breed in the Arctic or along the Atlantic Coast that travel through the area.

Affected Environment: Table A.8.3-1 in Appendix A of the Vineyard Wind 1 final EIS (BOEM 2021a), the SFWF final EIS (BOEM 2021b), and COP Appendix AA (BRI 2023), all incorporated here by reference, describe baseline conditions and the impacts, based on IPFs assessed, of ongoing and future activities other than offshore wind. These are further discussed below in the context of this Project. This section addresses potential impacts on bird populations that use inland, coastal, and offshore habitats, including both resident birds that use the Lease Area during all of (or portions of) the year and migrating birds with the potential to pass through the Lease Area during fall and/or spring migrations. Detailed information regarding species potentially present can be found in COP Appendix AA (BRI 2023) and COP Appendix K (VHB 2023). Given the differences in life history characteristics and habitat use between offshore, inland, and coastal bird species, the sections below provide a separate discussion of each group. This section also discusses migratory birds as well as bald and golden eagles. In addition, this section addresses federally listed threatened and endangered species, but further information is provided in the Project BA prepared for the USFWS (BOEM 2022, 2023a). Unless stated otherwise, special-status bird species are expected to be impacted similarly as described in general for other birds.

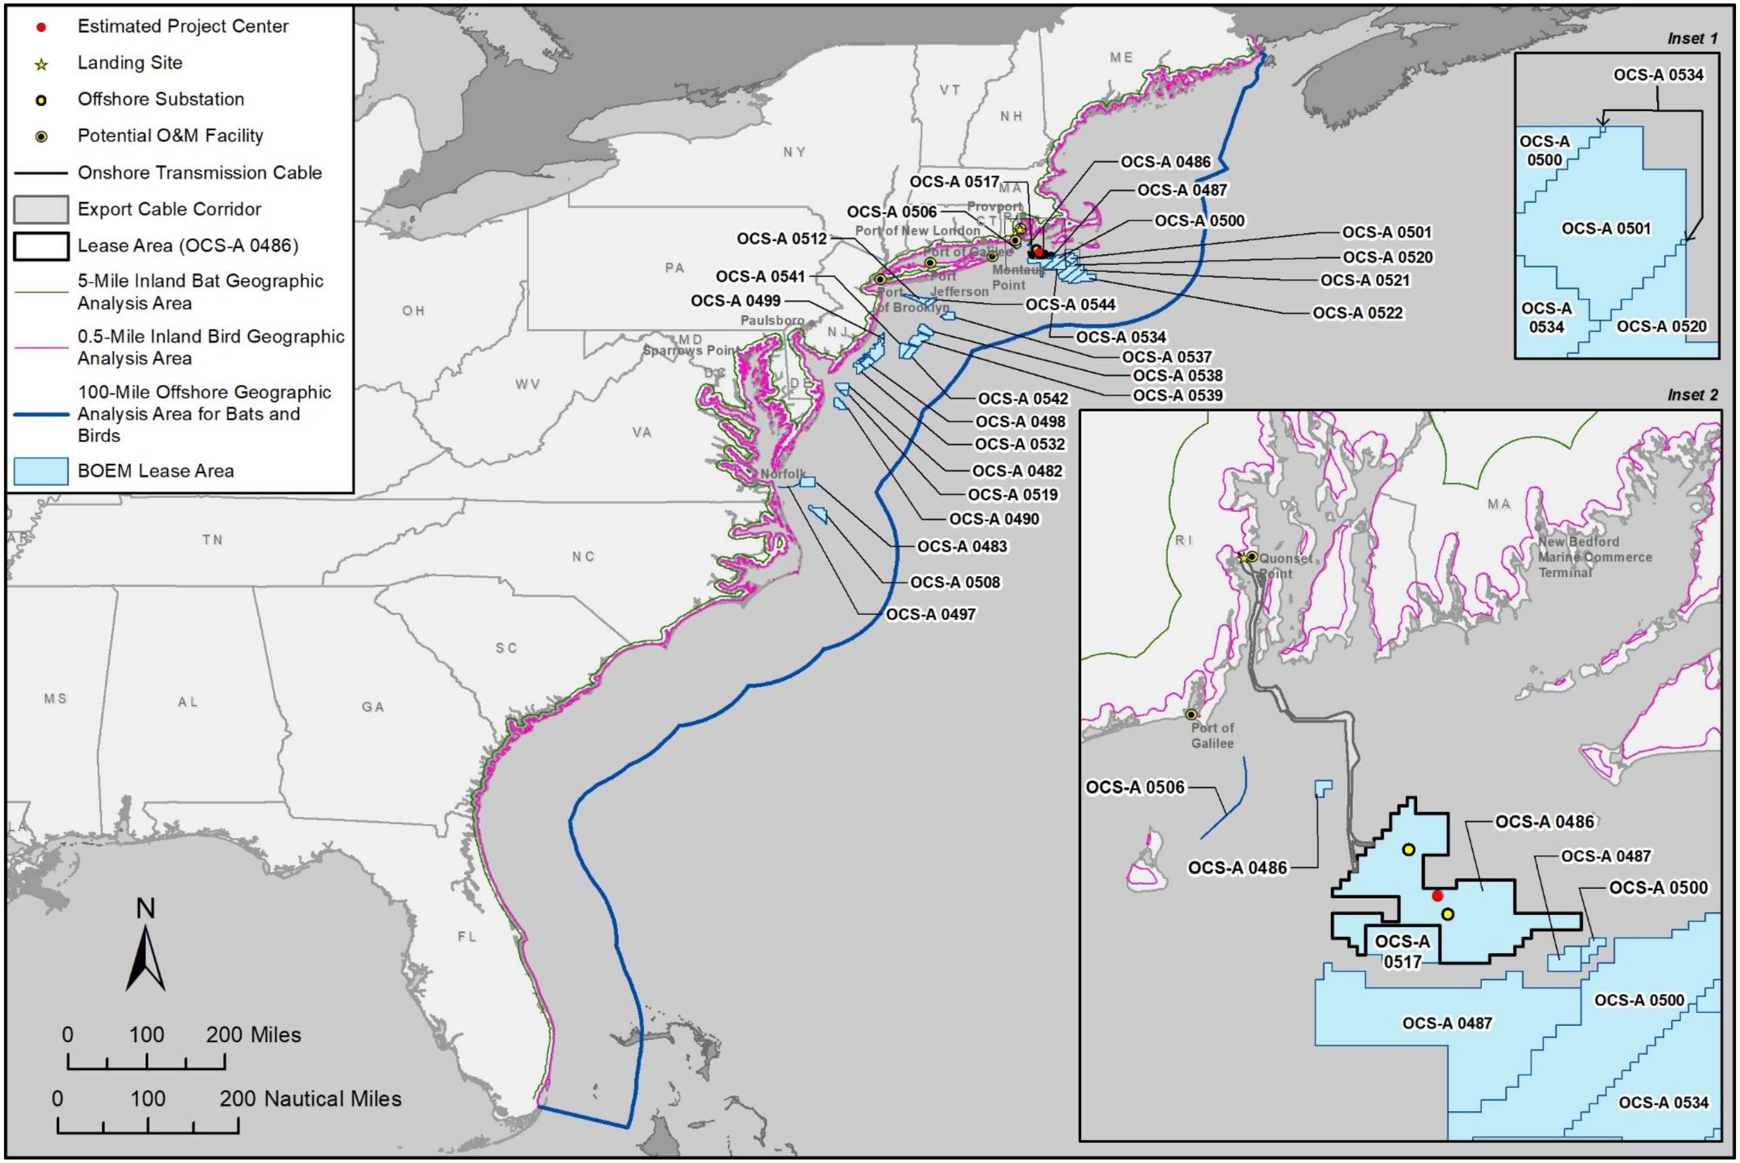

Figure 3.7-1. Geographic analysis area for birds.

### Migrating Birds

The Atlantic Flyway, which follows the U.S. Atlantic coast, is an important migration route for many bird species moving from breeding grounds in New England and eastern Canada to winter habitats in North, Central, and South America. Bays, beaches, coastal forests, marshes, and wetlands provide important stopover and foraging habitat for migrating birds (MMS 2007). Both the onshore and offshore facilities associated with the Proposed Action are located within the Atlantic Flyway. Bird species using this flyway during spring and fall migrations have the potential to encounter proposed Project facilities. Despite the level of human development and activity present, the Mid-Atlantic Coast plays an important role in the ecology of many bird species. Chapter 4.2.9.3 of the Atlantic OCS EIS/EA (BOEM 2014a), incorporated here by reference, discusses the use of Atlantic Coast habitats by migrating birds.

All native birds (except certain game birds protected under state laws) are protected under the Migratory Bird Treaty Act of 1918 (MBTA). The official list of migratory birds protected under the MBTA, and the international treaties that the MBTA implements, is found at 50 CFR 10.13. The MBTA makes it illegal to "take" migratory birds, their eggs, feathers, or nests.[1] Under Section 3 of Executive Order 13186, BOEM and the USFWS established an MOU on June 4, 2009, which identifies specific areas in which cooperation between the agencies would substantially contribute to the conservation and management of migratory birds and their habitats (MMS and USFWS 2009). The purpose of the MOU is to strengthen migratory bird conservation through enhanced collaboration between the agencies. One of the underlying tenets identified in the MOU is to evaluate potential impacts to migratory birds and design or implement measures to avoid, minimize, and mitigate such impacts as appropriate (MMS and USFWS 2009: Sections C, D, E(1), F(1–3, 5), G(6)).

Within the Atlantic Flyway, much of the bird migration activity is concentrated along the coastline (Watts 2010). Waterbirds use a corridor between the coast and several miles out onto the Atlantic OCS, whereas land birds tend to use a wider corridor extending from the coastline to tens of miles inland (Watts 2010). Although both groups may occur over land or water within the Atlantic Flyway and may extend considerable distances from shore, the highest diversity and density are centered on the shoreline. Migrating terrestrial species using the Atlantic Flyway may follow the coastline during migration or use more direct flight routes over expanses of open water. Many marine birds also make annual migrations up and down the eastern seaboard (e.g., gannet, loon, and sea ducks), taking them directly through the northeastern region in spring and fall. This results in a complex ecosystem where the community composition shifts regularly and where temporal and geographic patterns are highly variable. The region supports large populations of birds in summer, some of which breed in the area (e.g., coastal gulls and terns). Other summer residents (e.g., shearwaters and storm-petrels) visit from the Southern Hemisphere (where they breed during the austral summer). In the fall, many of the summer residents leave the area and migrate south to warmer regions and are replaced by species that breed farther north and winter in the northeastern region of the United States.

BOEM funds scientific studies and partners with the USFWS to better understand how migratory birds use the Atlantic OCS and to refine the understanding of the risks from development to migratory species (BOEM 2020). BOEM uses information from these studies, the USFWS, and the scientific literature to

[1] As described under 50 CFR 10.12, "Take means to pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to pursue, hunt, shoot, wound, kill, trap, capture, or collect."

avoid leasing areas with high concentrations of migratory birds that are most vulnerable to offshore wind development. In addition, BOEM's stakeholder engagement during the delineation of the adjacent MA WEA resulted in the exclusion of 14 Atlantic OCS blocks that overlapped with high value sea duck habitat (BOEM 2013). BOEM worked with the USFWS to develop standard operating conditions for commercial leases and terms and conditions of plan approval that are intended to ensure that the potential for adverse impacts on birds is minimized. The standard operating conditions have been analyzed in recent EAs, consultations for lease issuance and site assessment activities, and BOEM's recent approval of the Virginia Offshore Wind Technology Advancement Project (BOEM 2015). Some of the standard operating conditions originated from BMPs in the ROD for the 2007 *Programmatic Environmental Impact Statement for Alternative Energy Development and Production and Alternate Use of Facilities on the Outer Continental Shelf, Final Environmental Impact Statement* (MMS 2007:Section 2.7). BOEM and the USFWS will continue to work with lessees to develop postconstruction plans (e.g., those developed for the Vineyard Wind 1 final EIS (BOEM 2021a) and the SFWF final EIS (BOEM 2021b) aimed at monitoring the effectiveness of mitigative measures considered necessary to minimize impacts to migratory birds with the flexibility to consider the need for modifications or additions to the measures.

**Regional Offshore and Inland Birds**

The Lease Area is located within the Mid-Atlantic Bight, an oceanic region spanning Cape Cod, Massachusetts, to Cape Hatteras, North Carolina. A broad group of bird species may pass through the Lease Area and surrounding area, including migrants (e.g., raptors and songbirds), coastal birds (e.g., shorebirds, waterfowl, and waders), and marine birds (e.g., seabirds and sea ducks). See Table 3-1 in COP Appendix AA for a list of species that may pass through the Lease Area (BRI 2023). A high diversity of marine birds uses the Lease Area because it is located at the northern end of the Mid-Atlantic Bight, which overlaps northern and southern species assemblages (BRI 2023). Avian surveys were conducted within the Rhode Island Ocean Special Area Management Plan (OSAMP) study area, which included approximately 1,467 square miles (3,800 square kilometers [$km^2$]) with areas of the Block Island Sound, Rhode Island Sound, and the Atlantic continental shelf (Winiarski et al. 2012). Several methods were used to quantify the distributions and abundances of birds in the OSAMP study area, including land-based surveys, boat-based surveys, and aerial surveys. Survey data show that the use of these waters by coastal and marine birds is heaviest during winter months, peaking in early March to mid-April as birds prepare for and begin their spring migration. In general, coastal waters of less than 65.5 feet (20 m) in depth are important foraging habitat for diving ducks in winter, and nearshore shallow waters are important foraging habitat for locally breeding terns during summer months. Passerines use the air space during migration periods, and Block Island is an important stopover and resting spot for many species. Figures 3-7, 3-10, 3-12, and 3-13 in the Project's COP Appendix AA (BRI 2023) depict shorebirds; herons and egrets; songbirds; and coastal ducks, geese, swans, and grebes observed by season during OSAMP surveys, respectively.

The Marine-life Data and Analysis Team (MDAT) bird models (Curtice et al. 2019; Winship et al. 2018) describe regional-scale patterns of abundance with a range of environmental variables to produce long-term average annual and seasonal models. The MDAT Version 2 relative abundance and distribution models were produced for 47 bird species using U.S. Atlantic waters from Florida to Maine and thus provide an excellent regional context for local relative densities estimated from OSAMP surveys (see Part IV of COP Appendix AA) (BRI 2023). Overall, the MDAT models indicate avian abundance is greater closer to shore than in the Lease Area (see Figure 3-6 in COP Appendix AA) (BRI 2023).

A variety of passerines and other birds migrate along the Atlantic Coast and could fly over the onshore facilities' locations. Although most of the U.S. coastline is disturbed from previous anthropogenic uses, there are several different key habitats present that are suitable to a range of wildlife species. Bird species observed during field investigations and a list of birds that could occur based on habitat preferences within the GAA are listed in Tables C-1 through C-3 in Appendix C in COP Appendix K (VHB 2023).

Overall, birds in the northeastern United States are subject to pressure from ongoing activities, particularly accidental releases of fuel/fluids/hazardous materials (hazmat), sediment, and/or trash and debris; new cable emplacement; interactions with fisheries and fishing gear; and climate change. More than one-third of bird species that occur in North America (37%, 432 species) are at risk of extinction unless significant conservation actions are taken (North American Bird Conservation Initiative [NABCI] 2016). This is likely representative of the conditions of birds within the GAA. The northeastern United States is also home to more than one-third of the human population of the nation. As a result, species that live or migrate through the Atlantic Flyway have historically been, and will continue to be, subject to a variety of ongoing anthropogenic stressors, including hunting pressure (approximately 86,000 sea ducks harvested annually [Roberts 2019]), commercial fisheries bycatch (approximately 2,600 seabirds killed annually on the Atlantic [Hatch 2017; Sigourney et al. 2019]), and climate change, all of which have the potential to adversely impact bird species. According to the NABCI, more than half of the offshore bird species (57%, 31 species) have been placed on the NABCI watch list because of their small ranges, small and declining populations, and threats to required habitats (NABCI 2016). Globally, monitored offshore bird populations have declined by nearly 70% from 1950 to 2010, which may be representative of the overall population trend of seabirds (Paleczny et al. 2015) that may forage, breed, and migrate over the Atlantic OCS. Overall, offshore bird populations are decreasing, although considerable differences in population trajectories of offshore bird families have been documented (NABCI 2016).

Coastal birds, especially those that nest in coastal marshes and other low-elevation habitats, are vulnerable to the rising sea level and the increasing frequency of strong storms due to global warming. According to the NABCI, nearly 40% of the more than 100 bird species that rely on coastal habitats for breeding or migration are on the NABCI watch list. Many of these coastal species have small population sizes and/or restricted distributions, resulting in an increased vulnerability to habitat loss/degradation and other stressors (NABCI 2016). These ongoing impacts on birds would continue regardless of the offshore wind industry. Some of the main drivers of bird population declines include habitat loss, habitat fragmentation, collisions with glass windows and power lines, invasive species, predators, toxic chemicals, and climate change (Mass Audubon 2011, 2013, 2017).

Avian exposure assessments for the Project were conducted for species-season combinations using MDAT and/or OSAMP data (BRI 2023). To assess bird exposure at the local (i.e., MI/RI WEA) and regional scales (i.e., U.S. Atlantic waters), the Lease Area was compared to other similarly sized areas in each dataset for each season and species. Estimated exposure for each season and species was given a final score (see Table 3-4 in BRI [2023]), which was categorized as minimal (a combined score of 0), low (combined score of 1–2), medium (combined score of 3–4), or high (combined score of 5–6). The exposure scores for each species and season, as well as the aggregated scores (e.g., the annual scores for each species and taxonomic group), should be interpreted as a measure of the relative importance of the Lease Area for a species/group, as compared to other surveyed areas in the region and in the northwest Atlantic. Qualitative exposure determinations were developed using the quantitative assessment of exposure (described above), other locally available data, existing literature, and species accounts. Maps showing the results of the exposure assessment can be found in Part VI of COP Appendix AA (BRI 2023).

The Lease Area is generally far enough offshore as to be beyond the range of most breeding terrestrial or coastal bird species. Coastal birds that may forage in the Lease Area occasionally, visit the area sporadically, or pass through on their spring and/or fall migrations include shorebirds (e.g., sandpipers, plovers), waterbirds (e.g., cormorants, grebes), waterfowl (e.g., scoters, mergansers), wading birds (e.g., herons, egrets), raptors (e.g., falcons, eagles), and songbirds (e.g., warblers, sparrows). Overall, except for migratory falcons and songbirds, coastal birds are considered to have minimal exposure to the Lease Area. Falcons, primarily peregrine falcons (*Falco peregrinus*), may be exposed to the Lease Area. Of the marine birds, loons, sea ducks, gulls, terns, and auks received up to a medium overall exposure assessment. Some migratory songbirds, particularly blackpoll warblers (*Setophaga striata*), may also be exposed to the Lease Area during fall migration (BRI 2023).

**Special-Status Species**

Three bird species listed under the ESA are present in the region: piping plover (*Charadrius melodus*) (threatened), rufa red knot (*Calidris canutus rufa*) (threatened), and roseate tern (*Sterna dougallii*) (endangered). The Atlantic population of piping plover nests on beaches in the northeastern U.S. coastal region and will also migrate (spring and fall) through the Lease Area to and from breeding sites. Rufa red knots winter in southern states or in Central or South America and may pass through the Lease Area during migration (spring and fall) in transit to and from Arctic breeding sites. Roseate terns also migrate through the Lease Area in the spring and fall on their way to and from breeding sites in New York, the New England states, and Atlantic Canada.

BOEM prepared a BA to address Project effects to federally listed species under the jurisdiction of the USFWS, pursuant to Section 7 of the ESA (BOEM 2022, 2023a).

BOEM submitted the BA to the USFWS on November 17, 2022, requesting initiation of consultation under Section 7 of the ESA, and the USFWS responded on November 25, 2022, with a letter of consultation initiation. BOEM requested concurrence on its conclusion in the BA that the impacts of the proposed activities are expected to be discountable and insignificant, and thus *may affect but are not likely to adversely affect* piping plover, roseate tern, and rufa red knot. There are no critical habitats designated for these species in the action area (which includes the Lease Area) defined in the BA (BOEM 2022). An addendum to the BA was submitted to the USFWS on January 12, 2023, providing updates to the Stochastic Collision Risk Assessment for Movement (SCRAM) model for the rufa red knot (BOEM 2023a). The updated model output did not change the effect determinations in the November BA (BOEM 2022, 2023a). Another addendum to the BA was submitted to the USFWS on April 13, 2023. In this BA addendum, based on the updated SCRAM model, BOEM’s determinations for roseate tern and piping plover remained the same where the Proposed Action would not likely adversely affect roseate tern and piping plover for both SCRAM modeling scenarios (BOEM 2023b). However, BOEM revised its previous determination for the red knot and determined that the Proposed Action is likely to adversely affect red knot (BOEM 2023a). The USFWS, in its biological opinion (BO) dated May 30, 2023, concurred with BOEM’s determinations for roseate tern and rufa red knot but determined that the Proposed Action is likely to adversely affect piping plover as well (USFWS 2023).

To assess if any special-status species have the potential to occur in the onshore portion of the Lease Area, information from the Rhode Island Department of Environmental Management (DEM) Environmental Resource Map (ERM) was evaluated and an official species list from the USFWS IPaC tool was generated on September 28, 2019, regarding the landfall envelope, the onshore transmission cable routes, the OnSS, and the interconnection cable route (VHB 2023). VHB used the Information for Planning and Consultation (IPaC) tool to generate lists of bird species protected under the MBTA that have been designated as Birds of Conservation Concern (BCC) by the USFWS within the proposed limits of the onshore facilities during development of the *Onshore Natural Resources and Biological Assessment* (VHB 2023). BCC are species that without additional conservation actions are likely to become candidates for listing under the ESA (USFWS 2021). Table 4.3.6-3 in the COP provides the list of BCC with the potential to occur within the limits of the onshore facilities and indicates which of these species were observed during field investigations. According to the Rhode Island DEM ERM, there are no records of state-listed species within the GAA (VHB 2023). Migratory bird species with potential to occur near proposed onshore facilities are also presented in Table 4 of COP Appendix K (VHB 2023).

**Bald and Golden Eagles**

Eagles have additional federal protection (besides under the MBTA) under the Bald and Golden Eagle Protection Act. The general morphology of both bald eagles (*Haliaeetus leucocephalus*) and golden eagles (*Aquila chrysaetos*) dissuades long-distance movements in offshore settings (Kerlinger 1985). These two species generally rely upon thermal formation, which develops poorly over the open ocean, during long-distance movements. The bald eagle is present year-round in Massachusetts and Rhode Island, and its numbers have been slowly increasing over approximately the last 30 years. They are rarely observed in offshore surveys (Williams et al. 2015; all observations < 3.7 miles [6 km] from shore), which supports the notion that bald eagles do not venture far from land. Although bald eagles could be present near the proposed onshore facilities and would most likely be present in late April, no bald eagles were observed during field investigations (VHB 2023). Bald and golden eagles are not expected to occur within the Lease Area, but some potential exists for effects (e.g., displacement due to noise, habitat loss/modification, and injury/mortality due to contact with construction equipment) resulting from the construction and installation, O&M, and decommissioning of the onshore facilities.

## 3.7.2 Environmental Consequences

### 3.7.2.1 Relevant Design Parameters, Impact-Producing Factors, and Potential Variances in Impacts

This assessment analyzes the maximum-case scenario; however, there is the potential for variances in the proposed Project build-out, as defined in the PDE (see Appendix D). The Project design parameters that would influence the magnitude of the impacts on birds include the number, size, and location of WTGs; the location of the OnSS and ICF; the type of lighting to be used; the location of construction within the landfall work area and within the transmission cable envelope; and the time of year during which construction occurs. Impacts associated with construction of onshore elements of the Proposed Action during the breeding season for birds could be avoided if onshore construction occurs outside of this time frame.

The following EPMs would be implemented to minimize potential impacts to birds (see Appendix F, Table F-1):

- Revolution Wind evaluated siting alternatives for the OnSS using the criteria that included avoidance or minimization of disturbance to ecologically sensitive areas.
- Onshore facilities would be sited within previously disturbed and developed areas to the extent practicable, as follows:
    - The OnSS and ICF would be located on parcels that are already highly altered and include buried demolition waste.
    - The transmission cable would be located primarily in unvegetated and previously disturbed or developed ROWs.
- The onshore transmission cables would be buried and would therefore avoid the risk to avian and bat species associated with overhead lines.
- To the extent feasible, tree and shrub removal for onshore facilities would occur outside the avian nesting and bat roosting period (May 1 through August 15). If tree and shrub removal cannot be avoided during this season, Revolution Wind would coordinate with appropriate agencies to determine appropriate course of action.
- Construction and operational lighting would be limited to the minimum necessary to ensure safety and compliance with applicable regulations.
- Revolution Wind is committed to an indicative layout scenario with WTGs sited in a grid with approximately 1.15-mile (1-nm) × 1.15-mile (1-nm) spacing that aligns with other proposed adjacent offshore wind projects in the RI/MA WEA. This wide spacing of WTGs would allow avian and bat species to avoid individual WTGs and minimize risk of potential collision.
- Revolution Wind would comply with FAA and USCG requirements for lighting while using lighting technology (e.g., low-intensity strobe lights) that minimizes impacts on avian species.
- Accidental spill or release of oils or other hazardous materials offshore would be managed through the OSRP.
- All vessels would comply with USCG and EPA regulations that require operators to develop waste management plans, post informational placards, manifest trash sent to shore, and use special precautions such as covering outside trash bins to prevent accidental loss of solid materials. Vessels would also comply with BOEM lease stipulations that require adherence to NTL 2015-G03, which instructs operators to exercise caution in the handling and disposal of small items and packaging materials, requires the posting of placards at prominent locations on offshore vessels and structures, and mandates a yearly marine trash and debris awareness training and certification process.
- An SESC plan, including erosion and sedimentation control measures, would be implemented to minimize potential water quality impacts during construction and operation of the onshore facilities.
- Revolution Wind has developed a draft avian and bat postconstruction monitoring plan (see Appendix G and COP Appendix AA [BRI 2023]) for the Project that summarizes the approach to monitoring; describes overarching monitoring goals and objectives; identifies the key avian species, priority questions, and data gaps unique to the region and Lease Area that will be addressed through monitoring; and describes methods and time frames for data collection, analysis, and reporting. Postconstruction monitoring will assess impacts of the Project with the

purpose of filling select information gaps and supporting validation of the Project's avian risk assessment. Focus may be placed on improving knowledge of ESA-listed species occurrence and movements offshore, avian collision risk, species/species-group displacement, or similar topics. Where possible, monitoring conducted by Revolution Wind would build on and align with postconstruction monitoring conducted by the other Orsted/Eversource offshore wind projects in the Northeast. Revolution Wind would engage with federal and state agencies and environmental groups (eNGOs) to identify appropriate monitoring options and technologies and to facilitate acceptance of the final plan.

- Revolution Wind would document any dead (or injured) birds/bats found incidentally on vessels and structures during construction, O&M, and decommissioning and provide an annual report to BOEM and USFWS.
- Revolution Wind would continue to coordinate with RIDEM and NOAA NMFS regarding TOY restrictions through the permitting process and will adhere to requirements imposed by these agencies.
- Revolution Wind would use an ADLS (or a similar system), pursuant to approval by the FAA and commercial and technical feasibility at the time of facility design report (FDR)/Fabrication and installation report (FIR) approval.

These EPMs would be implemented across all alternatives; therefore, BOEM would not expect measurable potential variances in impacts across the alternatives.

See Appendix E1 for a summary of IPFs analyzed for birds across all action alternatives. IPFs that are either not applicable to the resource or determined by BOEM to have a negligible adverse effect are excluded from Chapter 3 and provided in Table E1-3 in Appendix E1. Offshore and onshore IPFs are addressed separately in the analysis if appropriate for the resource; not all IPFs have both an offshore and onshore component. Where feasible, calculations for specific alternative impacts are provided in Appendix E4, to facilitate reader comparison across alternatives.

Table 3.7-1 provides a summary of IPF findings carried forward for analysis in this section. Each alternative analysis discussion consists of the construction and installation phase, the O&M phase, the decommissioning phase, and the cumulative analysis. If these analyses are not substantially different, then they are presented as one discussion.

A detailed analysis of the Proposed Action is provided following the table. Detailed analysis of other considered action alternatives is also provided below the table if analysis indicates that the alternative(s) would result in substantially different impacts than the Proposed Action.

The Conclusion section within each alternative analysis discussion includes rationale for the effects determinations.

The overall impact to birds from any action alternative would be **minor** adverse, as the effects would be small, and the resource would recover completely, with no mitigating action required.

<tr><td>Accidental releases and discharges</td><td>Future offshore wind and non-wind activities could expose coastal offshore waters to contaminants (e.g., fuel, sewage, solid waste, or chemicals, solvents, oils, or grease from equipment) in the event of a spill or release during routine vessel use. Vessel compliance with USCG regulations would minimize trash or other debris; therefore, BOEM expects accidental trash releases from offshore wind vessels to be rare. All future offshore wind projects would be required to comply with regulatory requirements related to the prevention and control of accidental spills administered by the USCG and BSEE. OSRPs are required for each project and would provide for rapid spill response, cleanup, and other measures that would help to minimize potential impacts on affected resources from spills. Based on the low risk of spills from vessels due to implementation of safe handling, storage, and cleanup procedures, impacts from accidental spills and trash would represent a negligible adverse impact to birds.</td><td>Offshore: Potential adverse impacts to birds from contaminant discharges or releases or from improper disposal of trash or debris during construction would be avoided or minimized with adherence to federal, state, and local regulations regarding disposal of solid and liquid wastes, resulting in short-term negligible to minor adverse impacts. Accidental releases, if any, would occur infrequently at discrete locations and vary widely in space and time; for this reason, BOEM expects localized and temporary negligible adverse impacts on birds.<br>Impacts to birds from this IPF during operation and decommissioning of the offshore facilities would be similar to offshore construction impacts and result in short-term negligible to minor adverse impacts with compliance with USCG requirements and BSEE regulations.<br>In the context of reasonably foreseeable environmental trends, the combined impacts from this IPF from ongoing and planned actions, including the Proposed Action, would be likely limited in extent and duration and would result in localized and temporary negligible adverse cumulative impacts on birds.</td><td colspan="4">Offshore: Alternatives C through F would reduce the number of WTGs, potentially resulting in a reduced amount of offshore construction equipment and vessels required, thereby resulting in a negligible decreased risk for accidental releases and discharges. However, no measurable change from Proposed Action construction impacts to birds from this IPF is anticipated, which are expected to be localized and temporary negligible to minor adverse.<br>Impacts to birds from this IPF during operation and decommissioning of the offshore facilities are expected to be similar to offshore construction impacts, and no measurable change from Proposed Action construction impacts to birds from this IPF is anticipated, which are expected to be negligible to minor adverse.<br>Future offshore wind activities would contribute to an increased risk of spills and associated impacts due to fuel, fluid, or hazmat exposure. The contribution from future offshore wind and Alternatives C through F would be a low and non-measurable percentage of the overall spill risk from ongoing activities. In the context of reasonably foreseeable environmental trends, the combined impacts from this IPF from ongoing and planned actions, including Alternatives C through F, would be likely limited in extent and duration of a release and result in localized and temporary negligible adverse cumulative impacts to birds.</td><td>Offshore: Similar to Alternatives C through F, Alternative G would reduce the number of WTGs, resulting in no measurable change from Proposed Action construction, O&M, and decommissioning impacts to birds from this IPF is anticipated, which are expected to be localized and temporary (for construction) negligible to minor adverse.<br>Future offshore wind activities would contribute to an increased risk of spills and associated impacts due to fuel, fluid, or hazmat exposure. The contribution from future offshore wind and Alternative G would be a low and non-measurable percentage of the overall spill risk from ongoing activities. In the context of reasonably foreseeable environmental trends, the combined impacts from this IPF from ongoing and planned actions, including Alternative G, would be likely limited in extent and duration of a release and result in localized and temporary negligible adverse cumulative impacts to birds.</td></tr>
<tr><td></td><td></td><td>Onshore: Onshore, construction and HDD activities could result in the accidental releases of fuel, fluids, or hazmat; sediment; and/or trash and debris. Based on the low risk of spills due to implementation of safe handling, storage, and cleanup procedures, impacts from accidental spills and trash would represent a localized and temporary negligible adverse impact to birds.<br>The OnSS would require various oils, fuels, and lubricants to support its operation. Accidental discharges, releases, and disposal could indirectly cause bird habitat degradation; however, risks would be avoided through spill prevention and control measures and associated BMPs. Therefore, potential adverse impacts associated with discharges and releases are considered short term and localized negligible adverse.</td><td colspan="4">Onshore: Alternatives C through F would not alter impacts to onshore activities; therefore, impacts would be the same as those described for the Proposed Action: temporary to short term negligible adverse.</td><td>Onshore: Alternative G would not alter onshore activities; therefore, impacts would be the same as those described for the Proposed Action: temporary to short term negligible adverse.</td></tr>

| **Impact-Producing Factor** | **No Action Alternative** | **Alternative B (Proposed Action) up to 100 WTG** | **Alternative C (Habitat Alternative) 64–65 WTGs** | **Alternative D (Transit Alternative) 78–93 WTGs** | **Alternative E (Viewshed Alternative) 64–81 WTGs** | **Alternative F (Higher Capacity Turbine Alternative) 56 WTGs** | **Alternative G (Preferred Alternative) 65 WTGs** |
|---|---|---|---|---|---|---|---|
| | | In the context of reasonably foreseeable environmental trends, the combined impacts from this IPF from ongoing and planned actions, including the Proposed Action, would be localized and temporary due to the likely limited extent and duration of a release and result in **negligible** adverse cumulative impacts to birds. | | | | | |
| Anchoring and new cable emplacement/ maintenance | A small amount of infrequent construction impacts associated with onshore power infrastructure would be required over the next 6 to 10 years to tie future offshore wind energy projects to the electric grid. Typically, this would require only small amounts of habitat removal, if any, and would occur primarily in previously disturbed areas. Where future offshore wind activities overlap the GAA, there would be increased anchoring of vessels during survey activities and during the construction and installation, O&M, and decommissioning of offshore components. Disturbed seafloor from construction of future offshore wind projects and anchoring may affect diving birds' foraging success or may affect some prey species (e.g., benthic assemblages); however, impacts would be temporary and localized, and birds would be able to successfully forage in adjacent areas and would not be affected by increased suspended sediments and no population-level impacts would occur. Therefore, adverse impacts would be **minor**. | **Offshore**: Seafloor disturbed by cable installation and dredging prior to cable installation would result in turbidity effects that could reduce marine bird foraging success or have temporary and localized impacts on marine bird prey species. Vessel anchoring during construction would also result in increased turbidity. Individual birds would successfully forage in nearby areas not affected by increased turbidity/sedimentation during anchoring and cable emplacement, and only nonmeasurable **negligible** adverse impacts, if any, on individuals or populations would be expected given the localized and temporary nature of construction activities.<br>Other than temporary increases in turbidity from seafloor disturbance due to occasional vessel anchoring, no impacts to bird species are anticipated during the O&M phase for the offshore RWF or RWEC. Impacts from decommissioning would be similar to construction impacts unless the RWEC is abandoned in place: **negligible** adverse.<br>In the context of reasonably foreseeable environmental trends, the combined cable emplacement impacts from ongoing and planned actions, including the Proposed Action, could occur if impacts are in close temporal and spatial proximity. However, these adverse impacts from anchoring and cable emplacement would be **negligible** and would not be biologically significant. For these reasons, the Proposed Action when combined with other past, present, and reasonably foreseeable projects would result in short-term **negligible** to **minor** cumulative adverse impacts to birds. | **Offshore**: Alternatives C through F would reduce the number of WTG foundations and IACs. Reduced habitat disturbance from foundation and IAC installation could negligibly decrease turbidity that could alter the behavior of bird species. Therefore, BOEM would expect a similar but lower impact to birds than the Proposed Action: temporary, lasting up to 12 hours, localized and nonmeasurable **negligible** adverse impacts.<br>Similar to the Proposed Action, no impacts to bird species are anticipated during the O&M phase for the offshore RWF or RWEC. Impacts from decommissioning would be similar to construction impacts unless the RWEC is abandoned in place: **negligible** adverse.<br>Alternatives C through F would add 5,821 to 6,994 acres of seafloor disturbance from the RWEC and IAC installation and anchoring compared to the No Action Alternative, which represents up to 6% of the total seafloor disturbance estimated under the No Action Alternative. This would result in localized turbidity effects that could reduce marine bird foraging success or impact marine bird prey species. However, individual birds would be expected to successfully forage in nearby areas not affected by increased turbidity, and only nonmeasurable negligible impacts, if any, on individuals or populations would be expected given the localized and temporary nature of the potential impacts. In the context of reasonably foreseeable environmental trends, the combined cable emplacement and anchoring impacts from ongoing and planned actions, including Alternatives C through F, could occur if impacts are in close temporal and spatial proximity. However, these adverse impacts from anchoring and cable emplacement would be negligible and would not be biologically significant. For these reasons, these alternatives in combination with other past, present, and reasonably foreseeable projects would result in short-term **negligible** to **minor** adverse cumulative impacts to birds. | | | | **Offshore**: Similar to Alternatives C through F, Alternative G would reduce the number of WTG foundations and IACs, resulting in temporary (for construction), lasting up to 12 hours, localized and nonmeasurable **negligible** adverse impacts.<br>Similar to the Proposed Action, no impacts to bird species are anticipated during the O&M phase, and impacts from decommissioning would be similar to construction impacts unless the RWEC is abandoned in place: **negligible** adverse.<br>Alternative G would add 5,498 acres of seafloor disturbance from RWEC and IAC installation and anchoring compared to the No Action Alternative, which represents up to 5% of the total seafloor disturbance estimated under the No Action Alternative. This would result in localized turbidity effects that could reduce marine bird foraging success or impact marine bird prey species. However, individual birds would be expected to successfully forage in nearby areas not affected by increased turbidity, and only nonmeasurable negligible impacts, if any, on individuals or populations would be expected given the localized and temporary nature of the potential impacts. In the context of reasonably foreseeable environmental trends, the combined cable emplacement and anchoring impacts from ongoing and planned actions, including Alternative G, could occur if impacts are in close temporal and spatial proximity. However, these adverse impacts from anchoring and cable emplacement would be negligible and would not be biologically significant. For these reasons, these alternatives in combination with other past, present, and reasonably foreseeable projects would result in short-term **negligible** to **minor** adverse cumulative impacts to birds. |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTG | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
|---|---|---|---|---|---|---|---|
| | | **Onshore**: Land disturbance and habitat alteration resulting from construction within the landfall work area may result in the direct injury or mortality of bird species. Mitigations like observing time-of-year restrictions on vegetation removal would avoid the breeding season of birds, thus reducing the likelihood of injury and/or mortality from construction activities. Therefore, the impacts (e.g., injury and/or mortality) resulting from land disturbance and habitat alteration would be temporary **negligible** adverse. Additionally, construction work within the landfall work area would occur largely outside of the breeding period of listed species that might nest in the area, and because use of the shoreline by shorebirds within the landfall work area has not been documented (VHB 2023), onshore impacts for listed species from land disturbance would also be **negligible** adverse.<br>Onshore transmission cable installation would also result in temporary ground disturbance. Most of the temporary ground disturbance would occur in previously disturbed areas along paved roads or parking lots and would not result in impacts to bird habitat.<br>Operation of the onshore transmission cable would pose no risk to birds because it would be buried. Land disturbance in the form of vegetation management would occur on a periodic basis to maintain vegetation at shrub height within the perimeters of the onshore facilities. Land disturbance as it relates to vegetation clearing may result in the direct injury or mortality of birds. However, mortality and injury impacts would be mitigated by observing time-of-year restrictions on vegetation removal that would avoid the breeding season of bird species. Therefore, the adverse impacts resulting from this IPF would be **negligible**.<br>The contribution of the Proposed Action on adverse cumulative impacts to birds from new cable emplacement or maintenance in the context of reasonably foreseeable onshore environmental trends within the GAA is expected to be **negligible** adverse. | **Onshore**: Alternatives C through F would not alter impacts to onshore activities; therefore, impacts would be the same as those described for the Proposed Action: **negligible** adverse. | | | | **Onshore**: Alternative G would not alter onshore activities; therefore, impacts would be the same as those described for the Proposed Action: **negligible** adverse. |
| Climate change | Impacts associated with climate change (i.e., increased storm severity and frequency, ocean acidification, altered | **Offshore**: Construction of the offshore facilities would result in a small temporary increase in GHG emissions within the GAA during the construction | **Offshore**: Alternatives C through F would reduce the number of WTGs, potentially resulting in a reduced number of GHG-emitting construction vessels and/or aircraft. However, no measurable change from Proposed Action construction impacts to birds | | | | **Offshore**: Similar to Alternatives C through F, Alternative G would reduce the number of WTGs, potentially resulting in a reduced |

|---|---|---|---|---|---|---|---|
| | migration patterns, increased disease frequency, habitat conversion, and increased erosion and sediment deposition) could result in long-term **minor** adverse risks to birds and could lead to changes in prey abundance and distribution, changes in nesting and foraging habitat abundance and distribution, and changes to migration patterns and timing. However, future offshore wind development activities may beneficially contribute to a broader combination of actions to reduce future impacts to birds from climate change over the long term due to reduced reliance on fossil fuel–generated energy sources. | phase. As a result, adverse impacts to birds from construction of the Proposed Action associated with climate change would be short term **negligible** adverse.<br>The expected impacts on climate change from operation of the offshore facilities alone would not result in a measurable increase in the adverse impacts to birds beyond those described under the No Action Alternative. In addition, operation of the Proposed Action could also contribute to a long-term net decrease in GHG emissions, but this change would likely not be measurable. Therefore, BOEM expects the impacts from the Proposed Action on climate change would be long term **negligible**.<br>The types of impacts from global climate change described for the No Action Alternative would occur under the Proposed Action. Therefore, long-term **minor** adverse and long-term **negligible** beneficial cumulative impacts to birds are expected. | from this IPF is anticipated, which are expected to be short term **negligible** adverse. Likewise, no measurable change from Proposed Action operational impacts to birds is anticipated, which are expected to be long term **negligible** adverse.<br>The types of impacts from global climate change described for the No Action Alternative would occur under Alternatives C through F. However, Alternatives C through F could also contribute to a long-term net decrease in GHG emissions. This difference may not be measurable but would help reduce climate change impacts. Therefore, long-term **minor** adverse and long-term **negligible** beneficial cumulative impacts to birds are expected. | | | | number of GHG-emitting construction vessels and/or aircraft. However, no measurable change from Proposed Action construction and O&M impacts to birds from this IPF is anticipated, and impacts are expected to be short term **negligible** adverse (construction) and long term **negligible** adverse (O&M).<br>The types of impacts from global climate change described for the No Action Alternative would occur under Alternative G. However, Alternative G could also contribute to a long-term net decrease in GHG emissions. This difference may not be measurable but would help reduce climate change impacts. Therefore, long-term **minor** adverse and long-term **negligible** beneficial cumulative impacts to birds are expected. |
| | | **Onshore**: Onshore impacts to birds associated with climate change from construction and decommissioning of the Proposed Action would be similar to those discussed above for offshore facilities and activities: short term **negligible** adverse.<br>No measurable climate change impacts to birds from O&M of the onshore facilities are expected. Therefore, the adverse impacts from this IPF are expected to be long term **negligible** adverse.<br>The types of impacts from global climate change described for the No Action Alternative would occur under the Proposed Action. Therefore, the combined impacts from this IPF from ongoing and planned actions, including the Proposed Action and cumulative impacts, are expected to be long term **minor** adverse. | **Onshore**: Alternatives C through F would not alter onshore activities; therefore, construction and operational impacts would be the same as those described for the Proposed Action: short term to long-term **negligible** adverse.<br>Cumulative impacts would also be the same as those described for the Proposed Action: long term **minor** adverse. | | | | **Onshore**: Alternative G would not alter onshore activities; therefore, construction and operational impacts would be the same as those described for the Proposed Action: short term to long term **negligible** adverse.<br>Cumulative impacts would also be the same as those described for the Proposed Action: long term **minor** adverse. |
| Light | Nighttime lighting associated with offshore structures and vessels could represent a source of bird attraction. Vessel lighting would be temporary and result in a **minor** adverse impact to birds; structure lighting may pose an increased collision or predation risk (Hüppop et al. 2006), although this risk would be localized in extent and minimized using BOEM lighting guidelines (BOEM 2021c; Kerlinger et al. | **Offshore**: Lighting used during construction would be limited to the minimum required for safety during construction activities to minimize potential impacts. Therefore, adverse impacts to birds from lighting during construction would be localized and temporary **negligible** to **minor** adverse.<br>Under the Proposed Action, up to 100 WTGs and up to two OSSs would be lit with USCG navigational and FAA hazard lighting. These lights have some potential to attract birds and result in increased collision risk (Hüppop et al. 2006). However, the mandatory use of | **Offshore**: Although the number and duration of construction vessels and work areas requiring nighttime lighting could be slightly reduced under Alternatives C through F, no measurable change from Proposed Action construction impacts to birds is anticipated, which are expected to be localized and temporary **negligible** to **minor** adverse.<br>Alternatives C through F would reduce nighttime lighting, thereby negligibly decreasing the risk of avian injury or mortality from collision with WTGs as compared to the Proposed Action, and impacts are expected to be long term **negligible** adverse.<br>Alternatives C through F would add 56 to 93 new WTGs with red flashing aviation hazard lighting to the No Action Alternative; these lights could attract birds and result in increased collision risk (Hüppop et al. 2006). Additionally, marine navigation lighting | | | | **Offshore**: Similar to Alternatives C through F, the number and duration of construction vessels and work areas requiring nighttime lighting could be slightly reduced under Alternative G, and no measurable change from Proposed Action construction impacts to birds is anticipated, and impacts would be localized and temporary **negligible** to **minor** adverse.<br>Alternative G would reduce nighttime lighting for operations, negligibly decreasing the risk of avian injury or mortality from collision with |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTG | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
| --- | --- | --- | --- | --- | --- | --- | --- |
| | 2010), and therefore would also be a **minor** adverse impact. | red flashing aviation obstruction lights, the avoidance of any steady-burning aviation obstruction lights, and the use of ADLS (see Table F-2 in Appendix F for details) are expected to minimize bird attraction and therefore collision risk (Kerlinger et al. 2010; Orr et al. 2016). For this reason, BOEM expects adverse impacts, if any, to be long term **negligible** adverse from offshore lighting.<br>Ongoing and future non–offshore wind activities are expected to cause short-term impacts, primarily from vessel lights. For these reasons, the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in long-term **negligible** to **minor** adverse cumulative impacts to birds, and no individual or population-level impacts would be expected. | would include one or more flashing white lights on each WTG and the OSSs and would be directed out and down to the water surface. Vessel lights during construction and installation, O&M, and decommissioning would be minimal and limited to vessels transiting to and from wind farm areas. Ongoing and future non–offshore wind activities are expected to cause short-term impacts, primarily from vessel lights. For these reasons, Alternatives C through F when combined with past, present, and reasonably foreseeable activities would result in long-term **negligible** to **minor** cumulative adverse impacts to birds because no individual or population-level impacts would be expected. | | | | WTGs as compared to the Proposed Action, and impacts are expected to be long term **negligible** adverse.<br>Alternative G would add 65 WTGs with red flashing aviation hazard lighting to the No Action Alternative; these lights could attract birds and result in increased collision risk (Hüppop et al. 2006). Additionally, marine navigation lighting would include one or more flashing white lights on each WTG and the OSSs and would be directed out and down to the water surface. Vessel lights during construction and installation, O&M, and decommissioning would be minimal and limited to vessels transiting to and from wind farm areas. Ongoing and future non–offshore wind activities are expected to cause short-term impacts, primarily from vessel lights. For these reasons, Alternative G when combined with past, present, and reasonably foreseeable activities would result in long-term **negligible** to **minor** cumulative adverse impacts to birds because no individual or population-level impacts would be expected. |
| | | **Onshore**: Most of the onshore construction would occur during the daylight hours, although some overnight lighting may occasionally be necessary during construction of the onshore facilities. However, this is not expected to have a measurable effect on bird behavior, therefore BOEM anticipates temporary **negligible** adverse impacts to birds.<br>During the O&M of the OnSS and ICF, yard lighting would be used for assessment of equipment. Most decommissioning activities would occur during the day, and overnight lighting would only be necessary if there is work in progress on-site or lights are left on for safety and security purposes. Therefore, the adverse impacts resulting from this IPF would be long term **negligible**.<br>Ongoing and future onshore activities could contribute to impacts to birds from light if they occur at the same time within the GAA. However, these effects are also expected to be localized and temporary and would not contribute to adverse cumulative impacts to birds in the GAA. | **Onshore**: Alternatives C through F would not alter impacts to onshore activities; therefore, construction and operational impacts would be the same as those described for the Proposed Action: temporary to long-term **negligible** adverse.<br>Cumulative impacts would also be the same as those described for the Proposed Action: localized and temporary **negligible** to **minor** adverse. | | | | **Onshore**: Alternative G would not alter impacts to onshore activities; therefore, construction and operational impacts would be the same as those described for the Proposed Action: temporary to long-term **negligible** adverse.<br>Cumulative impacts would also be the same as those described for the Proposed Action: localized and temporary **negligible** to **minor** adverse. |

|---|---|---|---|---|---|---|---|
| Noise | Multiple offshore wind project construction periods are anticipated between 2022 and 2027. Construction noise sources will include, most notably, pile driving as well as geological and geophysical surveys, offshore and onshore construction, and aircraft and vessel traffic. These would create noise and may temporarily impact some bird species by displacing them and changing their behavior. Vessel and aircraft noise could also disturb some individual diving birds, but they would acclimate to the noise or move away, potentially resulting in temporary displacement. Collectively, these noise sources would be temporary and localized, resulting in a **minor** adverse impact to these birds. | **Offshore**: **Negligible** to **minor** adverse impacts to birds would occur from construction noise related to pile driving as well as geological and geophysical surveys and aircraft and vessel traffic. These activities could flush birds in the path of vessels, causing temporary displacement from the area.<br>Impacts to birds from operational noise and decommissioning of the offshore facilities would be similar to offshore construction impacts and result in **negligible** adverse impacts.<br>Pile-driving and other construction noise and activity associated with the Proposed Action could add to baseline noise and activity associated with other offshore wind projects with overlapping construction periods. Therefore, the Proposed Action when combined with past, present, and reasonably foreseeable activities would result in **negligible** to **minor** adverse cumulative impacts to birds. | **Offshore**: Alternatives C through F would slightly decrease noise associated with pile driving for WTGs and other construction-related noise as compared to the Proposed Action, which are short-term **negligible** to **minor** adverse impacts.<br>No measurable change from Proposed Action O&M impacts is anticipated because operational noise sources and levels would be the same: long-term **negligible** adverse impacts.<br>Pile-driving and other construction noise and activity associated with Alternatives C through F could add to baseline noise and activity associated with other offshore wind projects with overlapping construction periods. Potential impacts could be greater if avoidance and displacement of birds occur during seasonal migration periods. However, Alternatives C through F's contribution would be limited in duration, negligible, and cease when construction ends. No individual fitness (i.e., a bird's ability to survive and reproduce) or population-level effects would be expected. Therefore, these alternatives when combined with past, present, and reasonably foreseeable activities would result in **negligible** to **minor** cumulative adverse impacts to birds. | | | | **Offshore**: Similar to Alternatives C through F, Alternative G would slightly decrease noise associated with pile driving for WTGs and other construction-related noise impacts as compared to the Proposed Action, which are short-term **negligible** to **minor** adverse impacts.<br>No measurable change from Proposed Action O&M impacts is anticipated because operational noise sources and levels would be the same: long-term **negligible** adverse impacts.<br>Pile-driving and other construction noise and activity associated with Alternative G could add to baseline noise and activity associated with other offshore wind projects with overlapping construction periods. Potential impacts could be greater if avoidance and displacement of birds occur during seasonal migration periods. However, Alternative G's contribution would be limited in duration, negligible, and cease when construction ends. No individual fitness (i.e., a bird's ability to survive and reproduce) or population-level effects would be expected. Therefore, these alternatives when combined with past, present, and reasonably foreseeable activities would result in **negligible** to **minor** cumulative adverse impacts to birds. |
| | | **Onshore**: Noise from traffic associated with construction and vegetation removal within the landfall work area and other onshore facilities could affect shorebirds, some seabirds, and land birds that use the terrestrial habitats in the immediate vicinity of construction activities through displacement or avoidance behavior of individuals and/or disruptions in communication, mating, and hunting. The impacts associated with construction would be similar to existing sources of noise and traffic in the local area and therefore are considered a temporary **negligible** adverse impact.<br>Temporary noise and construction-related traffic may occasionally be generated due to nonroutine maintenance. Infrequent vehicle usage within the OnSS and ICF may create temporary noise-related disturbance to birds adjacent to the OnSS. However, such disturbance would be short term, and normal avian activity would likely resume after the traffic | **Onshore**: Alternatives C through F would not alter impacts to onshore activities; therefore, impacts would be the same as those described for the Proposed Action: temporary **negligible** adverse. | | | | **Onshore**: Alternative G would not alter impacts to onshore activities; therefore, impacts would be the same as those described for the Proposed Action: temporary **negligible** adverse. |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTG | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |
|---|---|---|---|---|---|---|---|
| | | ceases. BOEM expects these adverse impacts to be **negligible**.<br>In the context of reasonably foreseeable environmental trends, the combined impacts from this IPF from ongoing and planned actions, including the Proposed Action, would be localized and temporary due to the likely limited extent and duration of noise and would result in **negligible** adverse cumulative impacts to birds. | | | | | |
| Presence of structures | Onshore land development or port expansion activities could result in limited loss of nesting and/or foraging habitat for some bird species. The presence of offshore structures can lead to impacts, both beneficial and adverse, on birds through fish aggregation and the associated increase in foraging opportunities as well as entanglement and gear loss/damage, migration disturbances, and WTG strikes and displacement. These impacts may arise from buoys, met towers, foundations, scour/cable protections, and transmission cable infrastructure. Therefore, these impacts would be **minor** adverse. | **Offshore**: The various types of impacts on birds that could result from the presence of structures during construction include fish aggregation and an associated increase in foraging opportunities as well as entanglement and fishing gear loss/damage, migration disturbances, and displacement. These impacts would be temporary, and BOEM expects them to be **negligible** adverse. **Negligible** to **minor** temporary adverse impacts from bird collisions with visible structures could occur during construction, depending on the species and number of individuals involved.<br>The primary impact to avian resources during operation would be collision with rotating turbine blades. The presence and operation of the offshore facilities may also result in displacement of waterbirds, waterfowl, seabirds, and phalaropes that use the area for foraging, resting, or nighttime roosting. Long-term adverse impacts would be **negligible** to **minor**, depending on whether birds are at high risk for collision and/or displacement or are able to access preferred habitat, and these impacts may change over time if birds become habituated to the presence of the WTGs and OSSs. Impacts to birds from decommissioning of the RWF and offshore RWEC would be similar to those described for the construction phase. The Project is not expected to affect special-status species populations.<br>Cumulative impacts on birds from the presence of structures associated with the Proposed Action when combined with past, present, and reasonably foreseeable activities would be long term **minor** adverse and long term **minor** beneficial. | **Offshore**: Alternatives C through F would reduce the number of WTGs, potentially resulting in a reduced amount of offshore construction equipment and vessels required. However, because bird exposure to vessels and installation infrastructure would be temporally limited to the construction period, the behavioral vulnerability to collision with construction equipment under Alternatives C through F is expected to be the same as described for the Proposed Action, which are **negligible** to **minor** temporary adverse impacts.<br>During operations, Alternatives C through F would reduce the number of WTGs, potentially allowing for improved maneuverability for birds through the Lease Area and negligibly decreasing the risk of injury or mortality from collision with WTGs as compared to the Proposed Action, and impacts are expected to be long term **negligible** to **minor** adverse.<br>Alternatives C through F would add 56 to 93 additional WTGs and up to two OSSs compared to the No Action Alternative. The total cumulative foundations on the Atlantic OCS would be 3,146 to 3,183, and the Project would account for less than 4% of that total number. Adverse impacts to migration patterns or collision risk from these additional turbines would be negligible and persist until decommissioning is complete. Additionally, beneficial impacts to foraging near offshore structures would similarly be negligible and persist for the life of the Project. Therefore, cumulative impacts on birds from the presence of structures associated with these alternatives when combined with past, present, and reasonably foreseeable activities would be long term **minor** adverse and long term **minor** beneficial. | | | | **Offshore**: Similar to Alternatives C through F, Alternative G would reduce the number of WTGs and is expected to result in the same impacts as described for the Proposed Action, which are **negligible** to **minor** temporary adverse during construction and long term **negligible** to **minor** adverse during operations.<br>Alternative G would add 65 WTGs and up to two OSSs compared to the No Action Alternative. The total cumulative foundations on the Atlantic OCS would be 3,155, and the Project would account for less than 3% of that total number. Adverse impacts to migration patterns or collision risk from these additional turbines would be negligible and persist until decommissioning is complete. Additionally, beneficial impacts to foraging near offshore structures would similarly be negligible and persist for the life of the Project. Therefore, cumulative impacts on birds from the presence of structures associated with these alternatives when combined with past, present, and reasonably foreseeable activities would be long term **minor** adverse and long term **minor** beneficial. |
| | | **Onshore**: Impacts from habitat alteration and land disturbance on coastal and terrestrial bird habitats generated from the construction of the onshore facilities would create habitat loss and conversion, | **Onshore**: Alternatives C through F would not alter impacts to onshore activities; therefore, impacts would be the same as those described for the Proposed Action: temporary to long-term **negligible** to **minor** adverse. | | | | **Onshore**: Alternative G would not alter impacts to onshore activities; therefore, impacts would be the same as those described for the Proposed Action: temporary to long-term |

| Impact-Producing Factor | No Action Alternative | Alternative B (Proposed Action) up to 100 WTG | Alternative C (Habitat Alternative) 64–65 WTGs | Alternative D (Transit Alternative) 78–93 WTGs | Alternative E (Viewshed Alternative) 64–81 WTGs | Alternative F (Higher Capacity Turbine Alternative) 56 WTGs | Alternative G (Preferred Alternative) 65 WTGs |

| | | affect bird habitat use, and possibly create habitat degradation. During the breeding season, clearing of trees or vegetation could result in destruction of nests, adversely impacting some individuals. However, lasting impacts to local breeding populations are not anticipated. Collisions between birds and vehicles or construction equipment have some limited potential to cause injury and mortality. Therefore, impacts to birds from construction of onshore facilities would be short term **negligible** to **minor** adverse.<br>The OnSS and ICF would be visible structures that would result in permanent bird habitat conversion and loss. The OnSS access road and fenced-in property would become nonhabitat and result in habitat fragmentation. The conversion of forested cover type outside the OnSS and ICF fences would alter the structural diversity within a forested area by adding more edge habitat. Considering the adjacent landscape consists primarily of residential and commercial developments with some undisturbed areas of ruderal forested swamp, the adverse impacts to birds from the OnSS and the ICF on forested habitat fragmentation would be long term **negligible** to **minor**.<br>The potential for avian mortality or injury due to the low risk of collision with the OnSS and related structures would be a long-term **minor** adverse impact. The potential for avian avoidance behavior related to habitat conversion and loss from the OnSS would also be a long-term **minor** adverse impact. Adverse impacts to birds from habitat fragmentation related to a visible change in the landscape during decommissioning would be **negligible** because local populations would have adapted to the landscape changes.<br>The presence of these structures when considered in the context of ongoing and planned actions within the GAA would be a very minor risk of mortality or injury to birds due to collision, and generally, the changes to the habitat conditions would result in avoidance behavior and may influence bird habitat selection. Therefore, BOEM anticipates long-term **negligible** to **minor** adverse cumulative impacts to birds. | | | | | **negligible** to **minor** adverse. |

### 3.7.2.2 Alternative A: Impacts of the No Action Alternative on Birds

#### 3.7.2.2.1 Impacts of the No Action Alternative

Under the No Action Alternative, baseline conditions for birds (see Section 3.7.1) would continue to follow current regional trends and respond to IPFs introduced by other ongoing activities and by permitted and constructed offshore wind COP projects within the GAA for birds. These IPFs are described and analyzed in Appendix E1.

#### 3.7.2.2.2 Cumulative Impacts
